Fig. 31—Reactance Curves for a Coupled Circuit Likely to Give but a Single Frequency

If the two circuits are tuned to the same frequency but are constructed so that

$$M^2 < L_1 C_2 R_2^2 \qquad (2)$$

where $L_1 = L_p + L_g$, the reactance introduced (W) will be such as to produce only one intercept for Z. The curves indicating the primary oscillation circuit reactance X_1, the introduced reactance W, and the resulting reactance Z, are shown in Fig. 30. The above expression gives a critical value a trifle too high, for if $M^2 = L_1 C_2 R_2^2$ there are still three intercepts but they are close together and a slight reduction in M makes them merge into one. This expression was derived by equating the slope of the primary oscillation reactance curve to the negative slope of the introduced reactance curve W at the resonant value. Thus by constructing this type of circuit with two circuits tuned to the same frequency, and such that the primary one has a large ratio of L_1 to C_o, or the secondary one has a small ratio of $(L_2 + L_3)$ to C_2, a single frequency circuit can be obtained and full power delivered into the secondary circuit.

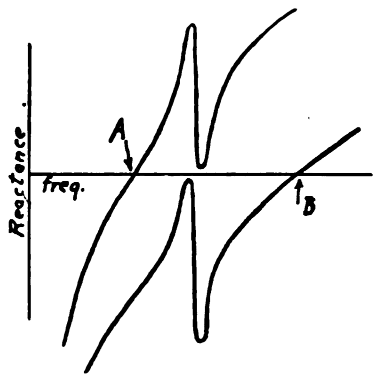

Fig. 32—Other Reactance Curves Similar to Fig. 31 Which Give Only a Single Frequency

When the two circuits are not tuned to the same frequency, it is comparatively easy to cause oscillations to occur at one frequency only. In Fig. 31, X stands for the reactance of the primary circuit $(L_g + L_p)\, C_o$. W stands for the reactance introduced from the secondary circuit $(L_2 + L_3)\, C_2$ which is tuned to a much lower frequency. The total primary reactance is given by Z. This gives two possible frequencies F and G, but by proper proportionment, frequency G will never occur. The effective inductances of L_g and L_p,

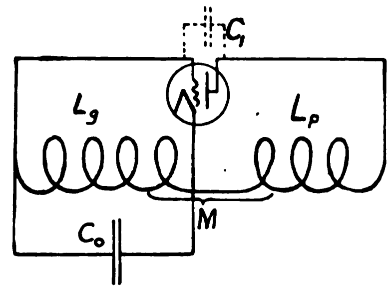

Fig. 33—A Feed-Back Circuit as it Occurs in Practise

together with the coupled tuned circuit at frequency G, are too low in comparison to the resistance and capacity C_o to allow oscillations to occur and oscillations will occur only at F.[4]

By choosing the coupling and detuning the circuits properly, reactance curves of the form in Fig. 32 can be secured. One curve has the intercept at A only and the other at B only. In one case the secondary circuit is tuned enough lower than the primary to make only one intercept real, the others being imaginary. In the other case the secondary is tuned enough higher than the primary to accomplish the same thing.

16. Feed-back Circuits

In the previous discussion of feed-back circuits (section 10) it was mentioned that they often operated in a manner differing from that usually supposed. In Fig. 33 is shown the usual feed-back circuit with the capacity between the plate and grid represented by C_1. This circuit as shown has two tuned circuits, $L_g\,C_o$, and $(L_g + 2\,M + L_p)\,C_1$. This circuit can be resolved into the Hartley type circuit by substituting for $L_g\,C_o$

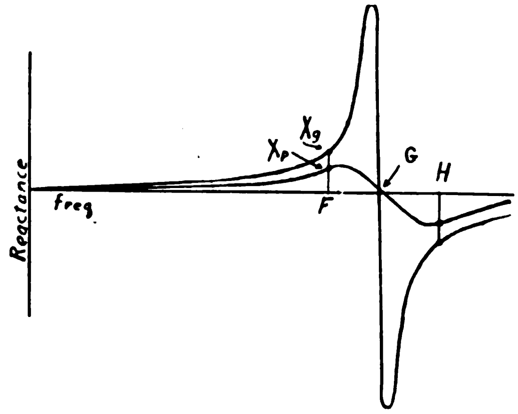

Fig. 34—Reactance Curves for Feed-Back Circuit of Fig. 33

its effective inductance, and for L_p, the effective inductance, due to its coupling with $L_g\,C_o$. Curves showing these are given in Fig. 34. The frequency of oscillation will not be the resonant frequency of $L_g\,C_o$ (G) but will be frequency F at which the effective grid and plate reactances X_g and X_p are equal to the grid-plate capacitive reactance. The frequency of oscillation will thus always be below the resonant value of $L_g\,C_o$. The behavior of the reversed feed-back circuit Fig. 18 is the same.

If this circuit has an inductive reactance between the grid and plate, such as can be produced by connecting an inductance L_o as in Fig. 25, the circuit will operate as a Colpitts circuit, above resonance. The frequency will be the value H in Fig. 34 which gives the capacitive reactance for the grid-filament and plate-filament branches.

Feed-back circuits usually operate in the manner just described when used for high frequencies. They operate in the first mentioned manner (f fixed by $L_g\,C_o$) for low frequencies. There is no sharp line of demarkation, as sometimes a circuit can be made to operate either way. It is rather a function of the values of inductances, capacities, and resistances than of frequency, but the relative capacities are to a considerable extent dependent upon the frequency.

These circuits will often oscillate in this manner when there is no mutual inductance between L_p and L_g, in which case the actual value of L_p must be sufficient to give the necessary amount of reactance X_p to make the circuit oscillate with $L_g\,C_g$ as an effective inductance, and C_1 as the capacity.

17. Direct- and Alternating-Current Branches

In drawing diagrams of oscillator circuits so far, the alternating-current parts only have been shown. This is in all cases sufficient for explanatory purposes as the direct-current paths are not all a part of the alternating-currents paths, and where not so may be omitted. In constructing any oscillator, the paths for the two kinds of current can be kept entirely separate except through the audion. It is only necessary to construct each circuit such that it does not conduct the other kind of current. In Fig. 35, the alternating- and direct-current paths of the Colpitts' oscillator are shown in which the only parts common to the two are the plate-filament and grid-filament paths of the audion, which is the minimum required in any oscillator. The alternating-current paths are broken up for direct current by the insertion of large condensers C_1 and C_2. These condensers in no way affect the frequency unless smaller than they should be made. Theoretically they should have zero reactance for the alternating current but practically they may have a reactance a few per cent, of the value of the impedance of that part of the audion with which they are in series. The direct-current paths are broken up for the alternating current by the choke coils $c\,h_1$ and $c\,h_2$. Choke coil $c\,h_2$ should have a reactance at the alternating-current frequency of several times the value of the impedance of the plate-filament path of the audion, and $c\,h_1$ should have a reactance of approximately the same value.

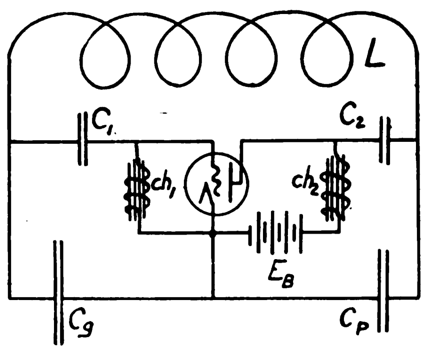

Fig. 35—Complete Colpitts Oscillator Circuit

The larger the values of these choke coils, the less will be the a-c. losses therein. Theoretically they should be infinite but practically the values mentioned before give satisfactory results. If they are large, they have no effect at all upon the frequency, but if too small, they may affect it slightly.

There are numerous other ways of constructing the direct- and alternating-current circuits, but they can all be summarized under the following: *The only common a-c. and d-c. paths required are the audion plate-filament and grid-filament paths. All external circuits solely for alternating current can have condensers inserted to prevent the flow of direct current, and all external circuits solely for direct current can have choke coils inserted to prevent the flow of alternating current. The separate a-c. and d-c. circuits must then each be properly connected to the audion.*

(To be continued.)

Economic Voltage of Long Transmission Lines

BY HENRY H. PLUMB

Asst. Engr., U. S. Reclamation Service, Electrical Division, Denver, Colo.

THERE has been a need of a rational method of determining the economic voltage for a proposed transmission line. This voltage has often been decided upon after making several lengthy cost estimates of lines at different operating voltages. It is the purpose of this paper to indicate a solution by an application of Kelvin's Law. While this law has certain limitations, of which the engineer must be aware, attention will be called to these at the proper time. Inasmuch as a choice of line conductor is generally limited to such standard sizes as are manufactured commercially, and a choice of voltage is limited in the same way, it is neither necessary nor advisable to find a solution which is accurate to any great degree

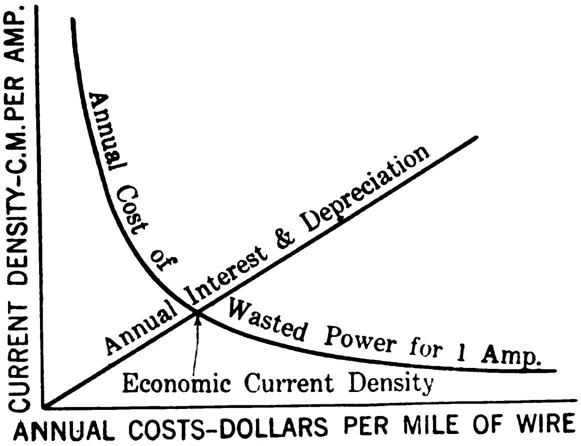

FIG. 1

of refinement. Capacity and skin effect are purposely ignored in obtaining the approximate solution. Such refinements can later be applied. The scope of this paper will be to present a rapid solution of the economic copper conductor as determined by Kelvin's Law, and using this as a stepping stone, the solution of the economic line voltage will be developed; the theory will then be extended to conductors other than copper. The principles given should be regarded as general, and should be supplemented by the use of good judgment in their application.

Kelvin's Law states that the most economical conductor is that one which gives the lowest annual charges, and that this occurs when the cost of the power wasted in the conductor is equal to the annual interest and depreciation on the conductor investment. The solution of this familiar problem has so often been presented in technical literature that it is unnecessary to review it here. This solution can be greatly simplified so that a very short calculation will suffice. Let the line current be taken at one ampere, and the solution will result in the economic current density in circular mils per ampere. Thus the size for any line current is immediately available. The current used should be figured for the desired power factor. Load factor can be accounted for by using the root mean square value of the ampere load curve. Fig. 1 indicates the economic current density at the intersection of the two curves of annual cost.

The curve showing the annual cost of wasted power is an hyperbola and any number of these may be drawn on the same sheet to cover any desired cost of power per kilowatt-hour. The interest and depreciation curve is a straight line, the position of which depends upon three items,—cost of copper per pound, interest rate, and depreciation rate. The interest and depreciation charge on a pound of copper will then be,

$$K = C\,(i + d)$$

where C = cost of copper cable per pound erected,
i = interest rate,
d = depreciation rate.

A number of lines may be drawn to represent different values of K, and Fig. 2 shows a form of chart which will solve Kelvin's Law for any values of cost of power and copper, and for any rates of interest and depreciation.

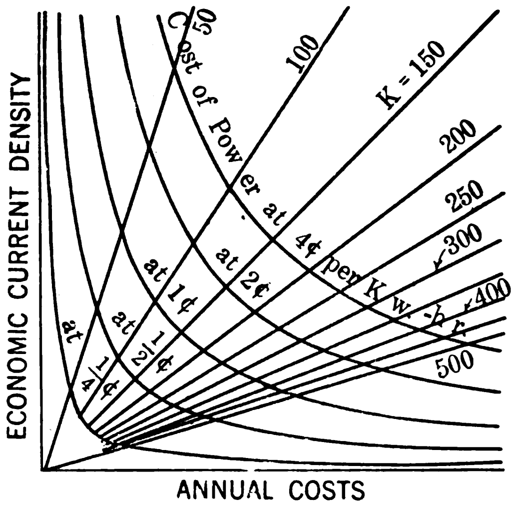

FIG. 2

Fig. 2 may be converted into a more convenient form by plotting cost of power as abcissas, as shown in Fig. 3.

Reference may now be made to the economic current density chart Fig. 5. This is a modification of Fig. 3, in that actual scales are supplied and plotted on logarithmic cross section in order that the curves of Fig. 3 may be plotted as straight lines and also that the scales of the chart may be increased to include any probable values of conductor and power costs.

This chart provides the means for determining the most economical voltage.

The size of copper required to transmit a given amount of power is reduced as the voltage is raised. For best economy the voltage should be raised as high as the corona losses will permit. The critical voltage at which corona begins to appear increases both with the size of conductor and with the spacing, but more rapidly with the former than with the latter. The size of cable, therefore, has the greater effect on the voltage at which corona appears. The effect of altitude is to reduce the voltage at which corona begins to form.

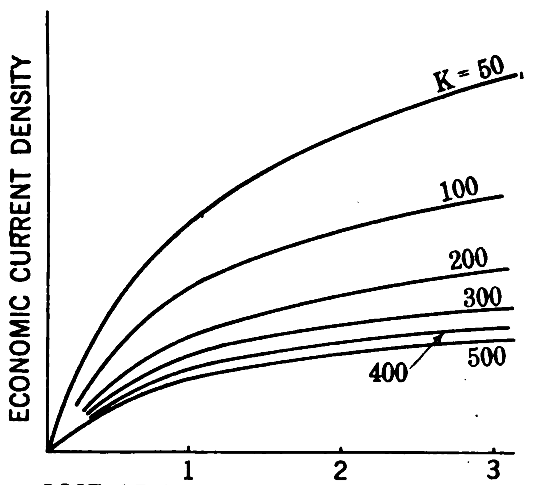

Fig. 3

It would appear then, that Kelvin's Law can be supplemented by a second law covering the line voltage which may be stated thus: The most economical voltage for long transmission lines is the highest voltage possible without excessive corona loss, upon a conductor of Kelvin's economic cross section. The truth of the above statement lies within certain limitations which must be clearly understood. The line must be long enough to prevent the cost of terminal apparatus from controlling the choice of voltage; the cost of switching apparatus and transformers increases very rapidly with the voltage, and for short lines this cost becomes the limiting factor instead of the line economics. It should be noted that the economic voltage for long lines, is a function of the power to be transmitted, and not of the distance of transmission as some rules of thumb have indicated. It is true however, that in some cases the line drop will be excessive when the economic voltage is used, in which case the economic conductor must be departed from, and a larger one used. This will permit the use of a higher voltage, which will further improve the line drop. The line drop could also be controlled by the use of synchronous condensers. Another limitation of this law lies in the fact that even in very long lines, the cost of the supporting structure and line insulators may increase to a point where they outweigh any saving in conductor cost which might be obtained by a further increase of line voltage. A third limitation is that while the line current is decreasing with an increasing voltage, the charging current is increasing and may reach a value much in excess of the load current. Up to a certain point this charging current may be beneficial to the characteristics of the line but it should be remembered that the charging current has a changing value along the length of the line and cannot be completely eliminated by control of power factor.

In spite of these limitations, it is believed that the economic line voltage should be calculated first, as here shown. A cost estimate of the line and terminal apparatus at the nearest standard voltage, and also at the next lower standard voltage, will show whether line conductors or terminal apparatus will dictate the choice of voltage. A conductor of Kelvin's economic section will give the lowest annual charges for a particular voltage; if the voltage is raised, the annual charges and first cost of conductor will both decrease. The most economical voltage for any length of line will therefore be that voltage which gives the lowest estimated first cost when conductors, insulators, supporting structures, terminal apparatus, erection costs, and upkeep are considered.

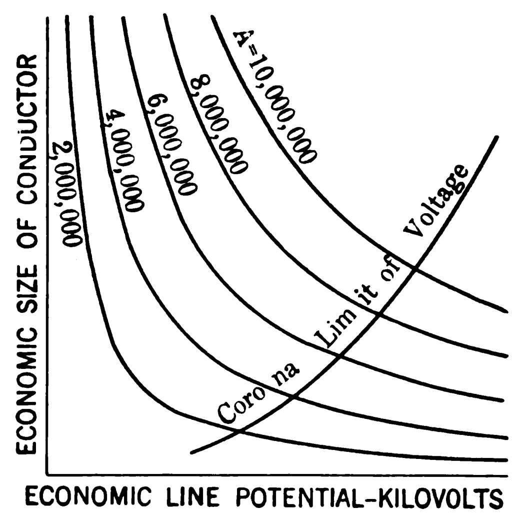

Fig. 4

Kelvin's economic section of conductor for any line voltage may be expressed by the equation,

$$S = D \frac{P}{\sqrt{3}\ E \cos \theta} \text{ for three phase lines where}$$

S = cross section in circular mils,

D = economic current density in circular mils per ampere,

P = root mean square value of power to be transmitted, in kilowatts,

E = kilovolts between conductors at generating end,

Cos θ = power factor of load.

Transposing, this becomes, $E\,S = \dfrac{D\,P}{\sqrt{3}\,\cos\theta} = A$

The second member of this equation is constant for a given set of design constants. This will at once

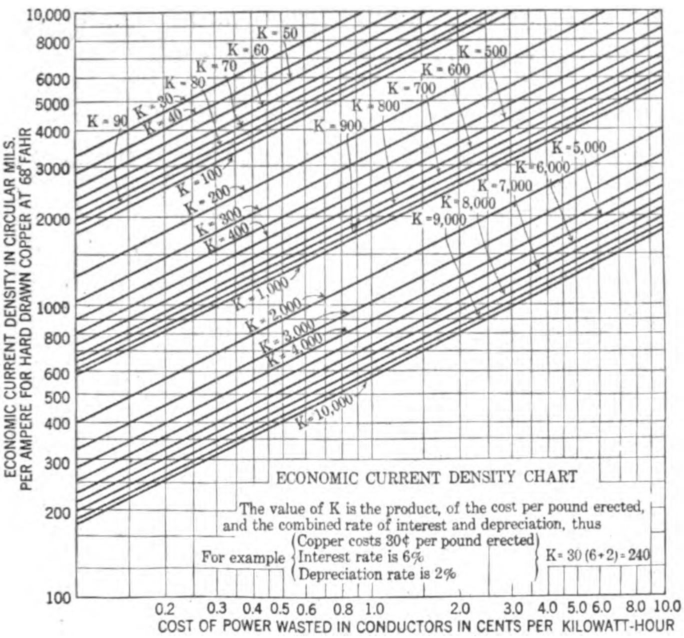

Fig. 5

be recognized as a standard form of the hyperbolic equation with variables in E and S, A being a constant. The whole family of curves can be drawn by suitably changing the value of A. Fig. 4 shows a number of these curves, and also a curve showing the variation of the critical corona voltage with the diameter of line conductor, for a given separation of conductors, and altitude above sea level.

After the value of A has been calculated for a particular problem it is only necessary to follow down the curve corresponding to the value of A as calculated, until it intersects with the corona limit of voltage curve. The asbcissa of this intersection indicates the economic line voltage, and the ordinate the economic cross section. Attention is now called to the economic voltage chart Fig. 6, which is drawn to definite scales as shown, and logarithmic cross section again employed. The corona voltage curves as shown for various altitudes and conductor spacings have been plotted from the tables given in the Standard Handbook for Electrical Engineers, Section 11, and are for stranded cables. It may be remarked that a stranded copper cable has a higher critical corona voltage than solid wire of equal conductivity. The critical corona voltages as shown by the curves are for "weathered" conductor and allowance is made so that the loss during storms will not be excessive. A careful check, using Peek's[1] formula for corona loss, should be made for accuracy under local conditions.

With proper handling these charts may also be used to determine the economic conductor and voltage when either aluminum or steel cored aluminum is employed as a conductor. Specific cost and copper equivalent charts Figs. 7 and 8, have been devised to facilitate the handling of aluminum conductors. By per cent specific cost is meant the ratio of cost of any conductor to a copper conductor, considering equal lengths and conductivities of each, using commercial hard drawn copper as a standard. Actual specific cost is the product of per cent specific cost and current price of hard drawn copper per pound. The copper equivalent chart shows the cross sections of copper and other conductors of equal conductivity. Curves have also been shown on these sheets for magnetic conductors, which could be used in the same way as aluminum were it not for the magnitude of the skin effect. These curves, therefore, may be used for direct current only. Allowance for skin effect has not been made for the copper and aluminum conductors, but since this effect ordinarily will not increase the resistance more than about 2 per cent, it is unnecessary to include this item in the determination of the economic voltage. Tests on steel cored aluminum show that it behaves very nearly as a non-magnetic conductor, and that the aluminum carries practically all of the current.

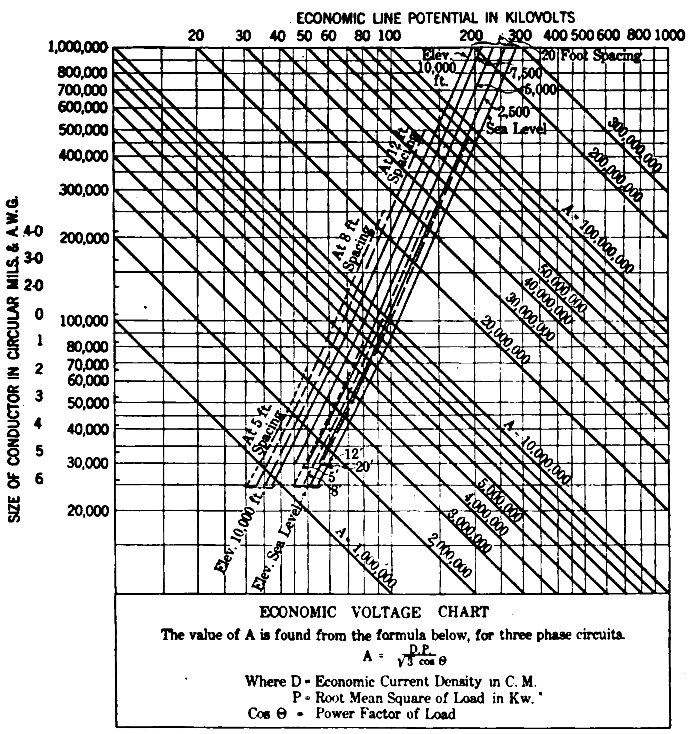

Fig. 6

A concise statement of procedure in the use of the accompanying charts is in order. For a copper conductor, figure the value of K as directed on the economic

1. Trans. A. I. E. E., Vol. 30, p. 1889.

current density chart. Starting with the cost of power at the bottom of the chart, follow the ordinate until it intersects the line corresponding to the value of K, interpolating if necessary. From this intersection follow the abscissa horizontally to the left and read off the economic current density.

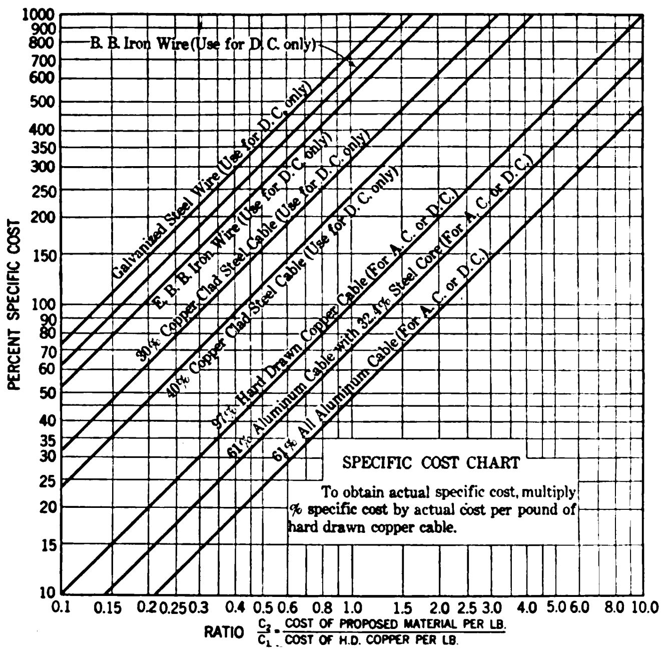

FIG. 7

Turn to the economic voltage chart, and calculate the value of A, using the economic current density found. Place a straight edge on the line corresponding to the value of A just found, interpolating if necessary. Choose now, the curve marked with the elevation of the proposed line. The intersection of this curve with the straight edge is the economic voltage for a 20-foot separation of conductors. If a smaller separation seems advisable, it can be interpolated by the use of dividers and the curves shown for reduced spacing. Having now a pencil point on the straight edge at the desired elevation and spacing, the economic voltage is read at the bottom scale, and the economic section of conductor at the left.

If an aluminum conductor is desired, turn to the specific cost chart and find the ratio C_2/C_1. Follow the ordinate corresponding to the decimal of the ratio until it intersects the diagonal line marked with the desired conductor and follow to the scale at the left and read off the per cent specific cost. The per cent specific cost multiplied by the actual cost of copper gives the actual specific cost. Turn now to the economic current density chart and use as before except that the cost of conductor will be the actual specific cost just found. The economic current density found from this chart is a current density for copper, equivalent in price to the aluminum. Turn to the copper equivalent chart and start on the left hand scale at the current density just found. Proceed horizontally to the line marked "Aluminum Cable" and proceed downward and read off the equivalent density in aluminum. If a steel core is contemplated for this cable, add to this density the *proportionate* circular mils of steel to be used and use this value of current density in the formula on the economic voltage chart. From this point on, use the same procedure as for copper cable.

From the foregoing study we may conclude that the voltage of long trunk lines may be determined by the method shown with small chance that the cost of terminal apparatus will affect the results. Transmission lines serving a number of substations cannot be handled in the same way for the reason that this method indicates different economic voltages for lines of different capacities. For such lines the voltage may be determined for the portion of line carrying the lightest load, and larger conductors used on other portions. As an alternative, the conductors may be made of uniform diameter in all parts of the system, the heavily loaded sections being served by copper conductors, the medium loads by aluminum, and the lightest loads in some cases by iron conductors. A combination of the two plans may be desirable under certain conditions. With the present tendency toward operating voltages of 220 kilovolts and over, the diameter of the cable becomes of great importance, overshadowing high conductivity. The use of iron may thus be given more consideration for these higher voltages, for branch lines especially.

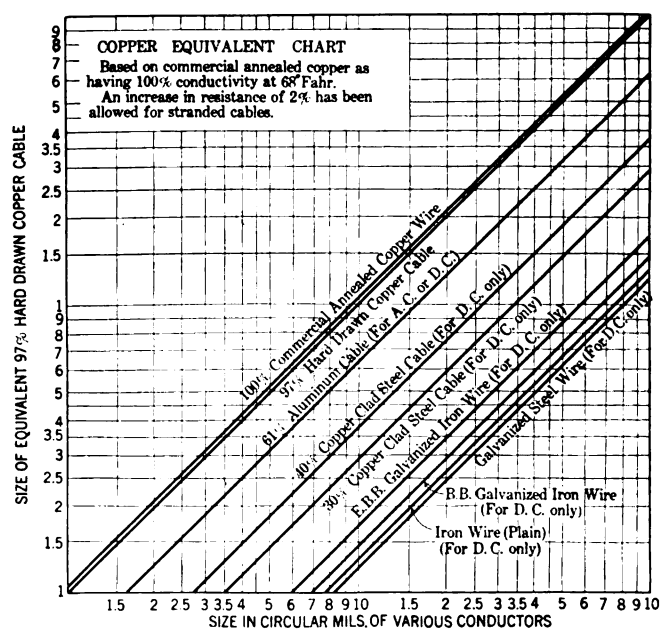

FIG. 8

A cost comparison of various conductor materials can readily be made by applying the method to the conductors in question. The first cost of conductor thus determined will be an indication of its relative value for the proposed line. Of two cables having

the same specific cost with different diameters, the one having the larger diameter will be more economical, from this standpoint, on account of its ability to carry a higher voltage with consequently lower line loss. A selection of conductor material should not be made, however, without a full consideration of its operating characteristics and special construction methods required.

A conductor is not being worked at its maximum economy unless the line voltage is reasonably close to the critical corona voltage. This is in accord with latest principles of line design, and high potential surges are more readily dissipated when the line voltage is just below the critical corona voltage. There is a definite, standard voltage, as well as a definite size and material of conductor to be employed for maximum economy in line design, and all of these points can be readily determined by this method of attack.

Submarine Detection in an Alternating Magnetic Field

APPENDIX A

The Amplifier

It has been mentioned that when using a detecting instrument of quite high sensitivity it is necessary to go to very large sizes of the magnet and detecting coil, in order to reach even moderate distances of detection, if no other means are used for increasing the sensitivity.

In all of the subsequent experiments amplifying tubes were used for increasing the sensitivity. The general principle of the operation of these tubes is now well known. The tube has a hot cathode, consisting of a filament excited by continuous current, a plate anode and an intermediate electrode, known as the grid. A continuous voltage is applied between the cathode and anode, resistance being connected in series. The hot cathode emits electrons, thus permitting a constant flow of current between anode and cathode. The amount of electronic emission of the cathode is extremely sensitive to slight variations in the potential gradient in its neighborhood. When used as an amplifier these potential variations are brought in by means of the grid. The resulting changes in the current passing through the tube cause corresponding changes in the voltage drop over the resistance in series with the plate, and consequently very small variations in the potential of the grid are transformed into much larger variations in the potential across the resistance.

The amplifier that was used for the greater part of the detection experiments was constructed specially for this work and had five stages of amplification, the successive stages being coupled by means of resistance.

The voltage amplification, as measured by the manufacturer, with an output resistance of 530 ohms and always using the low impedance stage for the output was as follows:

3 stages	110 times
4 "	1,300 "
5 "	18,000 "

In the experiments on land an input transformer was also often used with the amplifier. In voltage amplification this transformer was somewhat better than one additional stage and used with the transformer, the amplification as given by the manufacturers was:

3 stages	2,600 times
4 "	93,000 "
5 "	1,270,000 "

The impedance of the primary of the input transformer at 30 cycles was in the neighborhood of 70 ohms.

The input transformer was placed in a triple nest of wrought iron boxes, each 3/16 in. thick. Nevertheless, the transformer picked up enough inductive disturbance from the 30-cycle and other circuits to give serious trouble. On land this inductive electromotive force was reduced as much as possible by orienting the transformer until it had a small value. Any small residual from the 30-cycle circuit could be balanced out. The presence of this disturbance, however, often gave serious difficulty in determining the proper commutator setting and in adjusting the capacity to be used in the detecting circuit. On board ship, where the limitations of space prevented a proper choice of the location of this transformer, it was finally abandoned. The loss of amplification was made up by an additional[1] stage of the amplifier, the transformer and three stages having been used in the land tests and four stages of amplification without transformer being used on board ship.

Precautions in use of Amplifier. Having in mind the figures of amplification given above, it will be readily seen how necessary it is to eliminate all types of disturbance in the detecting and amplifier circuits. In using four, or even three stages, very minute disturbances

are amplified to magnitudes greater than that of the detection signal due to the submarine.

Perhaps the commonest types of disturbance are those due to (a) poor connections and contacts in battery, amplifier and detecting circuits; (b) poor electrostatic and electromagnetic shielding. The amplifier itself and all leads should, as far as possible, be enclosed in grounded shields; (c) duplication of ground connections. All shields, conduits and cases should be connected to the same ground; (d) mechanical vibration of the amplifier. Very slight motions of the filament with reference to the grid cause variations in the tube impedance with resulting variations in output voltage. Careful spring suspension of the amplifier is therefore advisable.

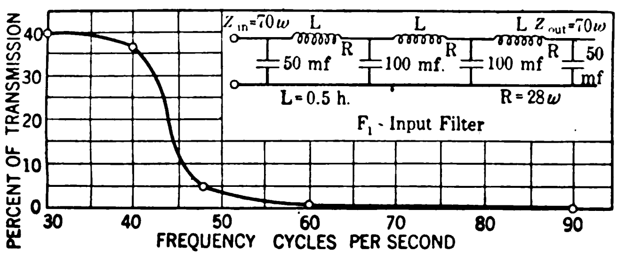

FIG. 6

Any of the foregoing types of disturbance which may be present will appear with no input in the detecting circuit, consequently with care all may be reduced to small values. On land it was found that they could be eliminated to such a degree that four and sometimes five stages could be used, resulting in a quiet galvanometer needle. There are, however, two other types of disturbance which are generally present in practise. They are (1) electromotive forces induced in the detecting circuit by neighboring circuits, (2) harmonic electromotive forces which are not balanced out.

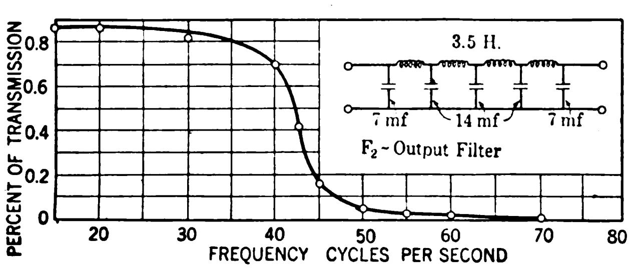

FIG. 7

When the inductive disturbances are of a frequency somewhere near 30 cycles, their presence is indicated by a slow oscillation of the galvanometer needle from one side to the other, the period depending upon the frequency of the disturbance. If the frequency of the disturbance is quite high, it may not cause a deflection of the needle, but result simply in a violent vibration. One disturbance was finally traced through oscillograms to a high commutator bar in a generator supplying some of the circuits of the neighboring building.

When the frequency of the disturbance, whether due to harmonics or to neighboring circuits, is greater than 40 cycles, it can be eliminated by means of "filters" or "pilot conductors" of the general character of those shown in Figs. 6, 7, 8 and 9. Fig. 7 shows a filter for use at the output end of the amplifier; Fig. 6 one designed for 70-ohm terminal conditions, that is, for use between the detecting coils and the primary of the input transformer. The pilot conductors were designed to go between successive stages of the amplifier.

In the experiments on shore the filters were found to be very effective in improving the conditions of balance. They cut out the higher frequencies, in accordance with the curves of Figs. 6 and 7 and do not seriously impair the sensitivity. They do, however, pick up inductive disturbances in the same way as that described for the input transformer. On land it was possible to eliminate these disturbances by proper location and orientation of the filters. On shipboard these preventive measures could not be readily carried out, owing to the limitations of space and the irregular distribution of the various sources of electric and magnetic disturbance. Consequently, in the final experiments on shipboard no filters were used.

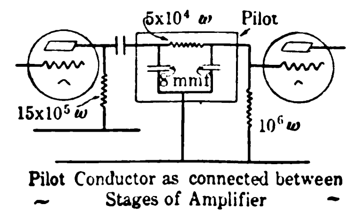

FIG. 8

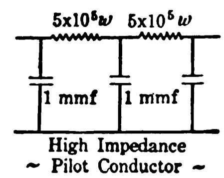

FIG. 9

The pilot conductors greatly improved the conditions of balance in the galvanometer circuit. There was, however, at the same time, a great loss in sensitivity on account of their high impedance. Extensive experiments were carried out with various forms of pilot conductor and invariably with the same result. It is impossible to state whether the improvement of the balance was due to the elimination of troublesome disturbances rather than to the reduction of the sensitivity.

Overloading of Amplifier. It is sometimes possible to balance the system so far as the 30-cycle detection signal is concerned and yet have present high frequency disturbances which do not appear in the balance other than as rapid vibrations of the needle about its zero position, with an amplitude say of three or four scale divisions. Under these circumstances it will sometimes be found that in passing from 3 to 4 stages, there is little or no increase of amplification. The explanation lies in the fact that at three stages the last tube of the amplifier has reached or passed its maximum rated load, the loading being caused by the amplified dis-

turbance. Several methods for studying this condition and its causes were available but cannot be given here.

The best conditions of balance without corresponding loss of sensitivity were always obtained by careful removal of causes of disturbance, identified by various methods. Obscure high frequency disturbances were still further removed by shunting a condenser of 0.0043 microfarads across the input of the amplifier. In this position the condenser is shunted across the high impedance secondary of the input transformer, a combination which constitutes a fairly efficient "low pass" filter.

Under the best conditions on shore, and with careful attention to all sources of disturbance, it was possible to obtain a balance using four stages of amplification and the input transformer, or five stages without the transformer. These balances were so sensitive and susceptible that they were obviously unsuited for work on shipboard. They were therefore not used for taking detection observations for use as a basis in computing results in practise.

Conditions on Shipboard. As anticipated, the conditions on shipboard were radically different from those encountered in the earlier work. Two most serious disturbances were those due to the vibration of the boat, caused by the engines, and the change in relative position of the magnet and the detecting coil, due to the straining of the hull of the ship. The effect of vibrations of the engines was considerably reduced by supporting the amplifier on springs. For these reasons it was found that the extreme value of amplification that could be used was four stages. As already mentioned, the input transformer was found to be unsuited to conditions aboard ship. The shunt to the galvanometer was also usually set much lower than 90 ohms and often as low as 10 ohms.

Under the above conditions, in quiet water and uniform speed, it was usually possible to secure a fair working balance. This balance, however, was invariably upset by sudden changes of speed, by rough water, or by a sharp change of course.

Toward the end of the experiments on board ship another amplifier with electro-magnetic coupling was used. This amplifier was not disturbed by a vibration of the boat to quite the same extent, apparently due to smaller, more compact, construction of the tube electrodes. This improvement was not however sufficiently great to permit an increased degree of amplification with resulting increase in the distance of detection.

APPENDIX B

Regulation for Constant Speed

Extreme constancy of speed is highly essential for maintaining the balance in the detecting circuit under conditions of high sensitivity.

Regulation by Tuning Fork. The method of speed regulation which was used throughout the greater portion of the experiments is indicated in Fig. 10. In this method the ultimate source of constant speed is an electrically operated tuning fork. A small rotary converter of the same frequency as the tuning fork is driven from the direct-current end and is loaded with a resistance on the alternating-current end, the load circuit being taken through a pair of contacts on the tuning fork, contact being made once during each half wave. The time interval of contact on the tuning fork is a fraction of the whole alternating-current period. If the speed rises, contact is made at an instant when there is a greater electromotive force and current, thus resulting in a greater load on the converter. If the speed goes down, the conditions are reversed, consequently the tendency of the change of load is to maintain the speed of the converter constant. This tendency can be made greater or more positive by inserting resistance in the armature circuit of the continuous-current end of the converter.

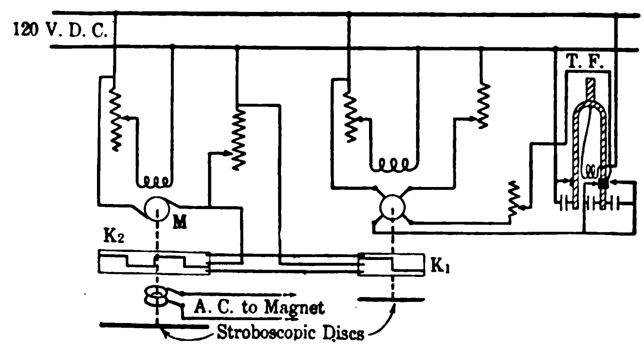

Fig. 10

The shaft of the small converter and that of the larger machine which is to be controlled are each supplied with a crown commutator. The number of commutator segments for each is chosen so that by their speeds the frequencies of reversal of the two commutators are the same. For example, in the experiments on S. C. No. 326, the speed of the generator for exciting the magnet was one half that of the regulating converter, consequently the numbers of commutator segments in the respective cases were four and two. The commutators were connected together, as indicated in Fig. 10, in such a way as to short-circuit a small resistance in the armature circuit of the main driving motor for a greater or less period, according as the commutators depart more or less from the position of exact coincidence of phase. The machines automatically find such a relative commutator phase relation than an increase in speed decreases the duration of short circuit of the armature resistance, and vice versa, so that the average voltage on the motor armature is such as to more or less exactly maintain the speed in a constant relation to that in the small converter, which in its turn is maintained constant by the tuning fork. The introduction of the small converter is necessary, since the tuning fork contacts will not carry the large

currents interrupted in the control of the considerably larger direct-current motor. The plan, as outlined, was used to control the speed of a 90 h.p., 230-volt, continuous-current motor operating at about 40 h.p. The speed of this machine was maintained constant by this method to within approximately. 0.5 per cent.

A number of modifications of the above method were tried, but without equal success. Among them were the following:

1. Apply a load to a small auxiliary alternating-current generator, mounted on the shaft whose speed

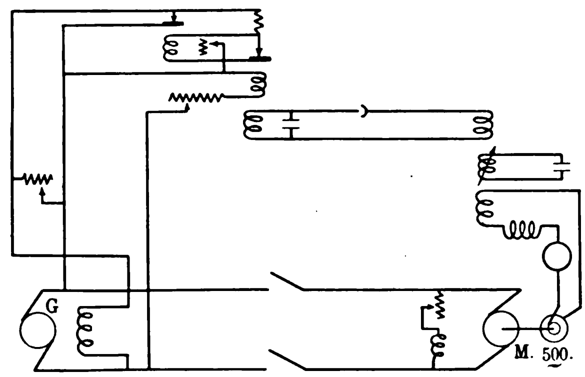

Fig. 11—Alexanderson Speed Control

is to be controlled, interrupt the load of the alternator by the commutators, thus regulating the speed in a manner similar to that in the combination of the small converter and tuning fork. The load necessary was found to be too great and the voltage between commutator segments too high, resulting in serious sparking.

2. The commutators were used to short-circuit a resistance in the field circuit of the main driving motor, rather than in its armature circuit. It was thought that the smaller value of current involved would result in an improvement in commutator action. However, the magnetic inertia of the field and the consequent slow action resulted in pronounced hunting of the larger machine.

Alexanderson Method of Speed Regulation. On shipboard motion of the ship caused the armature of the small converter, described in the foregoing method, and also that of the main motor generator to shift in their bearings, resulting in variable friction, and consequently in irregular variations of speed. Ball thrust bearings improved conditions somewhat, but not completely. The following method, due to Mr. E. F. W. Alexanderson, of the General Electric Co., was, through the courtesy of Mr. Alexanderson, studied as adapted to our needs, and finally put into operation.

The method is indicated by the diagram of Fig. 11. The essential features are a combination of an ordinary continuous-voltage regulator with a resonant alternating-current circuit. The resonant circuit is excited by a 500-cycle generator, geared to the shaft of the machine whose speed is to be controlled. The natural frequency of the tuning circuit is adjusted by variable reactance and capacity, so that the desired speed of the main generator is on the steep portion of the rising limb of the resonance curve. This circuit is loosely coupled to a circuit containing a vacuum tube rectifier and a part of one of the coils of the voltage regulator. When the speed rises for any reason, the current in the resonant circuit increases and thus operates the voltage regulator just as though there had been a rise in voltage. The regulator is therefore affected by either a rise in voltage or a change in speed, or both operating simultaneously. The 500-cycle generator was taken from an Army radio "pack set" and weighed only 40 lb.

This method of speed control is very positive in action. The closeness of its control was tested by comparison with a tuning fork. By a system of mirrors the amplitude of the tuning-fork vibration was greatly extended and a stroboscopic disk on the generator shaft permitted a close estimate of the momentary fluctuations of speed of the main generator shaft. These momentary variations were found not to exceed 0.04 per cent.

Temperature, or other slow variations of conditions, will cause a slow change in speed with the Alexanderson apparatus. Such slow changes, however, are of relatively small importance in their bearing on the balance of the detecting circuit. Sudden changes of small duration are the most troublesome. The use of the Alexanderson method therefore greatly improved the conditions of balance.

The tuning-fork method is free from the slow changes due to temperature, and it appears that a further refinement in speed control might be possible by using both the tuning-fork control and the Alexanderson control on the same shaft.

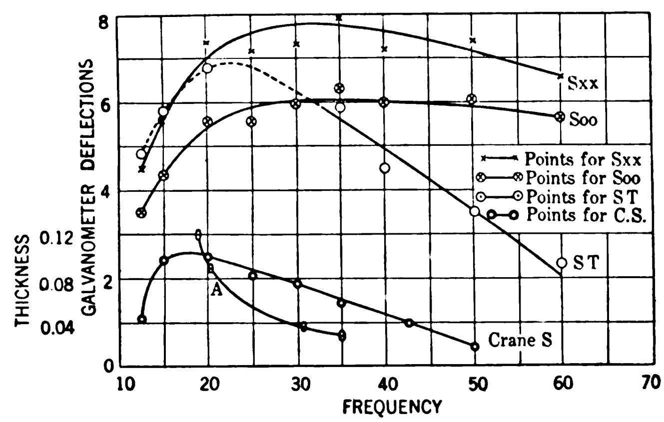

Fig. 12—Effect of Frequency on Sensitivity

APPENDIX C

Choice of Frequency

Early in the work at Baltimore a study was made, with a number of experimental submarine models, on the sensitivity of detection as affected by the alternating frequency. Some of the results are shown in Fig. 12.

The curves indicate that for every thickness tried

there is a frequency at which the deflection of the detecting instrument for a given distance of the submarine is a maximum. These curves were all taken with approximately constant flux in the magnet.

With a given strength of field at the submarine, due to its magnetization the electromotive force in the detecting coil rises with the frequency. The influence of secondary currents and eddy currents set up in the hull, however, also increases with the frequency, thus resulting in an increasing demagnetizing effect. The resultant maximum may therefore be due to the preponderance of the former effect at the low frequency, and of the latter effect at the high frequency.

With increasing thickness of the submarine, and indicated by the curves, the maximum of detection signal tends toward lower frequencies. (See curve *a*, Fig. 12, showing relation of thickness and maximum deflection). For the thickest submarine the maximum is also more sharply marked.

The earlier experiments with submarine models of the smaller thicknesses had indicated 30 cycles as the region of maximum sensitivity. The latter experiments, above described, rather indicate that a still lower frequency might be better suited for service in actual practise in which the thickness is greater. However, the relative distances and strengths of field at submarine and coil were different in several instances, thus introducing factors which are necessarily uncertain and which might therefore upset this conclusion. In any event, as indicated by the curves, there is relatively small gain in sensitivity in going from 30 cycles to say 15 cycles. As machines and other equipment adapted to 30 cycles were readily available, and those of lower frequency not obtainable within a reasonable time, the experiments were continued at 30 cycles.

APPENDIX D

Tests of Formula 11

The relations shown in Formula (**11**) were tested in the laboratory in an extensive series of experiments. Model submarines of different lengths, diameters, thicknesses and material were tried under as nearly as possible the same conditions. In addition, the inverse sixth power of Formula (**10**) was tested. No attempt will be made to include a complete account of these experiments here. The general results only will be given.

Formulas (**10**) and (**11**), for computing the distance of detection, show that if D is small compared with d, the signal should be inversely proportional to the sixth power of d. When D has a value that is more nearly comparable with the value of d, the increase of the signal with the decrease of d is proportional to some higher power of d.

The conclusion of the foregoing paragraph was readily tested by reading the variation of the signal in the detecting instrument with the approach of the submarine. With D equal to 5 ft. 8 in. and d decreasing from 15 ft., the signals were found to vary with approximately the inverse eighth power of d over the relatively short distance in which the comparison could be made. When D was reduced to 2 ft. or less, the average of a number of runs showed that the signal varied inversely as d to the power 6.2. A number of similar tests, all made with arrangement A of Fig. 1, indicated that the inverse sixth power was approached the smaller the value of D.

The tests as to the variation of the dimensions of the model were made with three models of the same size as S, but of different thicknesses, namely, 0.025 in., 0.0375 in. and 0.0625 in., and also with two models of different diameters, as well as different thicknesses. All were separable into several sections. (See Tables 1, 2 and 3).

The influence of the length of the model on the signal is given in Table I. The average ratio of the lengths in

TABLE I
INFLUENCE OF LENGTH OF SUBMARINE

the comparisons which are recorded is 2.06. The corresponding average of the ratio of the signals is 1.72. The curve of Fig. 13 shows clearly that when the length of the submarine is comparable with d, its effective length as a magnet decreases rapidly with the distance from the main magnet. It is therefore to be expected that this ratio, as observed on sections of varying length, should be lower than the ratio of the actual lengths. The last line in the table gives an exaggerated case of difference in the comparison of a 10-ft. submarine with a 16-ft. submarine. The ratio of signals is 1.14. This instance has not been included in taking the average mentioned above.

The influence of the diameter of the model is shown by the results of Table II. The average of a number of tests indicated that the signal increases directly as the diameter, the ratio of the diameters being 2 and the average ratio of the signals being 1.91.

The results of a study of the influence of the thickness of the wall of the model, shown in Table III, are not so definite. The ratio of thicknesses of wall is in two

cases 2.5. For the submarine of 1-ft. diameter the average ratio of signals was 1.92, but for models 2 ft. in diameter the ratio was only 1.13. A possible explanation may lie in the greater demagnetizing influence in circulating and eddy currents in the case of the model having larger diameter and greater thickness. The conclusion here is obviously not definite, but indicates at least some increase of signal of detection with increasing thickness of the shell of the submarine. It should be borne in mind, in all tests, of this character that there is a great element of uncertainty as to the continuity of the magnetic structure of an actual submarine. It seems quite possible that the caulking and painting of the plates may well interpose non-magnetic layers which would seriously offset the simple relations

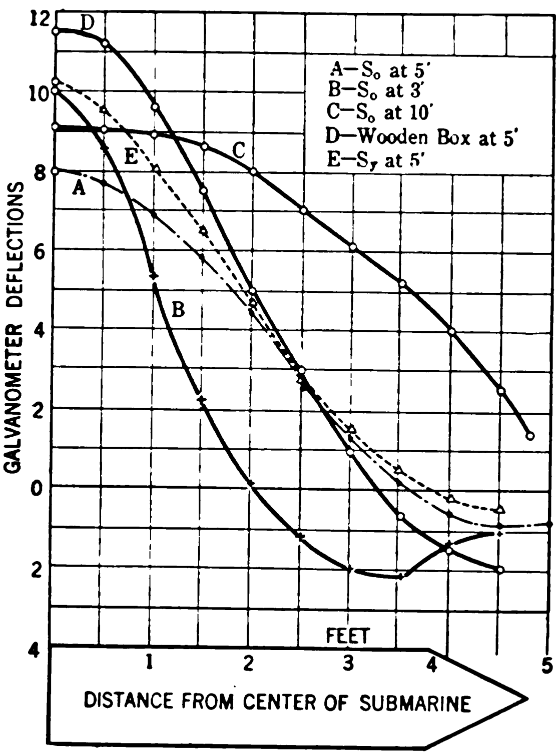

Fig. 13—Magnetization of Submarine

which are assumed in Formula (**11**). It was clearly recognized, through all the work of this character, that the experimental conditions probably differed markedly from those which would actually obtain in the case of the application to full size submarine. On the other hand, it appeared a matter of considerable importance that the approximate relations of the formulas should be tested.

By the method of derivation of Formula (**11**), it is shown that the distance of detection, using arrangement *B* of Fig. 1, should be greater than that of arrangement *A* by a factor the sixth root of 4, that is, 1.26. Owing to the limited distance of detection in the laboratory experiments, there are few possibilities for a convenient and certain test of this relation. From a number of tests in this direction only one will be given here:

Arrangement *A*. Distance for a standard signal—11.25 ft.

Arrangement *B*. Distance for the same signal—15 ft.

The ratio of these two distances is 1.33, indicating that the actual sensitivity of arrangement *B*, as compared with arrangement *A*, is greater than indicated by theory.

There appeared to be no reason why tests, of this character should be extended further to a more careful

TABLE II

determination. The object of all of this work was to check, to only an approximate degree, the relations of Formula (**11**), so that they might be used as a basis for the design of larger equipment.

APPENDIX E

Electric Balance in the Detecting Circuit

A question which arose early in the laboratory tests was the proper setting of the commutator for the maximum signal in the detecting coil due to the magnetized submarine. This question was answered experimentally by taking a number of detection observations with different commutator settings. A balance was obtained for each setting by rotating the balance coil *C'*, the detecting coil remaining fixed, and then bringing up the model submarine to a definite standard position.

TABLE III
INFLUENCE OF THICKNESS
Ratio of Thicknesses = 2.5

Diameter	Signal				Ratio of signals	
	0.0625		0.025			
	$d = 15'$	$d = 12'$	$d = 15'$	$d = 12'$	$d = 15'$	$d = 12'$
1'	3.35	17.5	1.75	8.2	1.91	2.14
1'	2.82	15.4	1.35	7.6	2.09	2.03

2'	2.35	15.3	2.7	18.5	1.17	1.23
2'	3.65	18.9	3.97	23.0	1.09	1.22

The conclusion from these experiments was that the phase of the signal from the submarine is practically co-incident with that from the main magnetic field due to the magnet, and that therefore the proper commutator setting for the submarine signal was the same as that pertaining to the electromotive force induced in the detecting coil by the magnetic field of the magnet. This conclusion was subsequently checked in the experiments afloat by making detection observations for different commutator settings. The simplest steps for obtaining a balance then are: to set the detecting coil with its plane approximately normal to the magnetic field, to cut out the balancing coil or rotate it until its plane is approximately parallel to the field, to insert a high non-inductive resistance in the detecting circuit in order to limit the current in the detecting instrument, inductance being already balanced with capacity, and then to rotate the brushes around the commutator to a point where the galvanometer deflection is zero. At this setting the current in the detecting circuit is chopped up into equal positive and negative quarter-waves. The commutator is then rotated 90 electrical degrees, in which position it will indicate, to a maximum degree, all disturbances in the detecting circuit which are in phase with the electromotive force induced in the detecting coil by the main field. The non-inductive resistance is now cut out, the balancing coil inserted and rotated to give a balance, as indicated by the detecting instrument.

In the early experiments, before the amplifier was used, it was found possible to obtain a very satisfactory balance with the above method, using a D'Arsonval suspension galvanometer of 83-megohms sensitivity, and the experiments of the type recorded on page 228 were taken under these conditions, but even at this time it was obvious that there were disturbances in the detecting system which could not be eliminated by the simple operations of commutator setting and rotating the balancing coil. At this point there began a study of the conditions of balance in the detecting circuit which extended through the entire period of the work, both ashore and afloat. With increasing sensitivity in the detecting circuit, there always appeared new types of disturbance which had to be attacked and, as far as possible, eliminated. In fact, the one problem in increasing the distance of detection is to increase the sensitivity of the detecting circuit, as shown in Fig. 2, without at the same time permitting the entrance of many types of common disturbance which are normally of greater magnitude than the signal due to the submarine.

Along with the various steps in the increase of the sensitivity, there was a continuous process of refinement of electric and magnetic screening and the rigid fastening of all leads and coil supports in the detecting circuit. It was found that this circuit must be grounded at one single point. If there are two grounds connected by a single stretch of wire in this circuit, under conditions of high sensitivity enough difference of potential arises to mask the signal.

Disturbance of the position of the galvanometer needle about its zero naturally led to studies of the commutator and of changes in voltage and frequency in their influence on the magnet excitation. The development of the commutator finally led to a rigid mounting on the end of the generator shaft, careful machine construction with narrow mica insulation between segments, and to quite narrow brushes with light spring tension. These brushes were usually made of three layers of brush copper with a thin steel backing for the spring tension. The commutator was kept clean by a rather sparing application, once or twice a day, of high-grade lubricating oil, with a clean rag.

Variations of both frequency and of voltage were found at once to upset the balance very violently. It became evident that the greater portion of the disturbances were due to these causes, especially to frequency variation. Efforts were directed not only to obtain constancy in these particulars, but also to a study of the possibility of compensating in some way the disturbances themselves. Since constancy of frequency is only a relative term, it is obvious that with increasing sensitivity possible disturbances, due to frequency variations, will continually appear.

If the system without amplifier is balanced, as described above, and the commutator be then rotated to successive positions, it will be found that the balance is upset, showing the presence of a residual disturbance in the detecting circuit after it is balanced. The wave form of this disturbance may be taken and while it is distorted in shape, its principal component is that of the fundamental 30-cycle frequency, thus showing the presence of an electromotive force which is displaced 90 degrees from that induced by the main field. This led to the question of a difference in phase in the electromotive forces in the detecting and balancing coils, and an experimental study promptly revealed the fact that with increasing distance from the magnet there was a continual lag in phase of the main magnetic field. It was subsequently found that this condition obtained with all three of the magnets. In the case of the laboratory magnet, M_1, for example, there was a lag of 4.5 electrical degrees in moving the detecting coil from a distance 4 ft. to a distance 17 ft. from the magnet. This residual may be balanced out in a number of ways, as described below, and in this way it was found that the disturbance due to frequency variation is very greatly reduced, and that due to voltage variation practically disappears when this residual is completely balanced out.

Two of the earliest efforts to balance out the residual electromotive force, due to the difference in phase in the electromotive forces in the detecting and balancing coil, should be described. In the first of these, the electromotive force in the detecting coil was balanced by a few turns taken completely around the main

magnet, the process of balancing being accomplished by rotating the detecting coil. It was found that by moving the balancing coil to different positions on the magnet, a place could be found for which a given change in frequency or voltage could be compensated; *i. e.*, on making this change there would be no upset of the zero reading of the detecting instrument. The second method involved moving a balancing coil to different positions in the neighborhood of the magnet in an effort to find a position in which the phase of the electromotive force in this coil was co-incident with that in the detecting coil. Sometimes this position could be found with resulting great improvement in the balance. Neither of these arrangements was satisfactory, the first because it compensated only for frequency

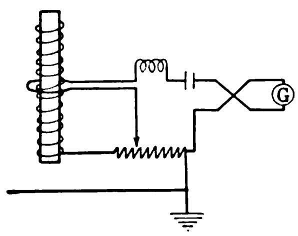

Fig. 14

and voltage changes of definite magnitude, and the second because the position described could not always be found.

The introduction of the amplifier greatly accentuated the influence of the residual electromotive force in the detecting circuit. Its presence became immediately evident in the balanced condition by a 60-cycle vibration of the galvanometer needle. The amplitude of this vibration would be normally two or three divisions of scale and thus became a ready means of determining the presence of a residual electromotive force. The vibration, or "wiggle," of the needle is obviously caused by the chopping up of the 30-cycle residual at its maximum point, since the commutator is set for a disturbance differing in phase from it by 90 electrical degrees.

Methods of Eliminating Residual Electromotive Force. Following is a list of some of the methods which were tried for eliminating the residual electromotive force in the detecting circuit.

1. Shunt the balancing coil with a non-inductive resistance, so that the electromotive force in the terminals of this resistance is in phase with the electromotive force in the detecting coil. See Fig. 2. This was the method finally adopted. The coil is rotated for balancing.

2. Introduce into the detecting circuit an electromotive force derived from the circuit exciting the magnet:

a. By resistance in series with the magnet winding, Fig. 14.

b. Inductively from a coil in series with the magnet winding and acting on the balancing coil.

c. Inductively from a coil excited by connection across a resistance in series with the magnet winding and acting on the balancing coil.

d. Inductively from a coil in parallel with the magnet winding.

e. Inductively from a coil excited from the terminals of the balancing coil.

3. Insertion of an electromotive force exactly equal and opposite to the residual electromotive force from a Drysdale alternating-current potentiometer arranged as a variometer:

a. Excited by split phase from the main generator.

b. Excited from a small two-phase generator mounted on the shaft of the main generator.

4. Omit the balancing coil and insert in the detecting circuit an electromotive force from the variometer exactly equal and opposite to the electromotive force in the detecting coil due to the main magnet field.

The residual electromotive force may be neutralized by any one of the methods mentioned above, by the following experimental adjustments:

1. Set the commutator for maximum current due to electromotive force in the detecting coil.

2. Balance C and C' by varying position or angle of C.

3. Shift commutator 90 electrical degrees, that is, for maximum current due to residual electromotive force.

4. Balance out the residual by resistance drop over resistance in series with magnet winding, or by any of the other methods described in the foregoing paragraph.

5. Shift commutator back 90 degrees.

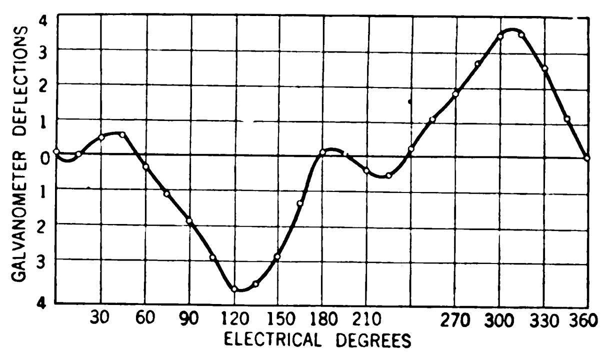

Fig. 15

6. A greatly improved balance will result, but if not yet perfect, the above process is repeated.

By the above methods the conditions of the balance were greatly improved, but they were still found to be very sensitive to changes in frequency. Although the residual was found to be balanced out, there was always to be found, by rotating the commutator or by taking an oscillogram, a highly distorted wave of current in the detecting circuit. The presence of this wave can be detected simply by rotating the brushes about the commutator, taking readings at different positions. Fig. 15 shows a curve taken in this way, after the sys-

tem is balanced and the 30-cycle residual removed, as far as possible, by one of the methods mentioned above. Obviously the curve of Fig. 15 does not show the true wave form, but serves only to indicate the presence of a disturbance made up of higher harmonic frequencies.

None of the foregoing methods of eliminating the residual electromotive force eliminated the disturbance due to frequency variation and several of them made this type of disturbance even worse.

Disturbances Due to Changes of Frequency. As has been already stated, the electromotive forces in the coils C and C' differ in phase. A number of causes for this may exist but the most obvious appears to lie in the difference in phase between the magnetic or stray field of the magnet winding alone, and that due to the main flux in the core of the magnet. These two fields differ in phase and combine in varying relative magnitudes at different points. This appears to be borne out by the fact that there is an increasing lag in phase with increasing distance from each of the magnets, M_1, M_2 and M_3. However, it will also be recalled that in close proximity to other magnetic and conducting masses there is also a shift in the phase of the magnetic field, undoubtedly due to magnetic and electric reactions of these masses. Whatever be the nature of the explanation of the shift in phase of the main magnetic field, it is obvious that the phase pertaining to any particular point will be different for different values of frequency.

The fields in the detecting and balancing coils are not unidirectional, but are rotating. This was readily determined experimentally in attempting to rotate a detecting coil so that its plane should be parallel to the field, and thus have in it no electromotive force. No such position could be found, and by the means mentioned it was readily possible to measure the relative magnitude to the two components of the rotating elliptical field at any point. For example, the magnitude of the right angle component in one position of M_1 was found to vary with the position of C between 1 per cent and 2 per cent of the principal component. With a change of frequency the relative magnitudes of these two components will also change.

In view of the foregoing, it would appear that the following are the principal causes which may lead to an upset of the electrical balance in the detecting circuit when a slight change of frequency occurs.

1. Inequality of phase between C and C'. Referring to the vector diagram in Fig. 16, if there exists a residual electromotive force R due to a difference in phase between C and C', a change of frequency will shift the position of the parallelogram and bring a component of R into the setting of the commutator. With a residual present equal to 50 divisions on the galvanometer a change of phase of 11 deg. would produce a deflection of 10 divisions.

2. If C and C' are in exact opposition in phase, a change in frequency will, in general, result in a shifting of the phases of C and C' in different amounts. This will cause a resultant electromotive force between them, a greater or less component of which will appear in the setting of the commutator. A simple calculation shows that in the case of M_3 and C_3 in the relative positions used on board ship, a phase difference 0.025 seconds would cause a deflection of 10 divisions on the galvanometer.

3. If C' is shunted so as to bring the electromotive force at its terminals into exact opposition with the electromotive force in C at one frequency, a change in this frequency will result in a change in both magnitude and phase of the electromotive force at the terminals of C'.

4. Since the magnetic fields at both C and C' are rotating, a change of frequency will change the relative values of the principal and right-angle components of these fields and, in general, by different amounts in the two coils, and so will result in an upsetting of the balance.

5. Under the best conditions of balance obtained, it has always been found that there is a residual current in the detecting circuit having a complicated wave form. This harmonic residual in the balanced condition is chopped up by the commutator for normal frequency. A change in the fundamental frequency will be multiplied correspondingly for higher harmonics which would naturally result in a displacement of the harmonic residual, so that it is no longer chopped up by the commutator, thus resulting in a zero upset.

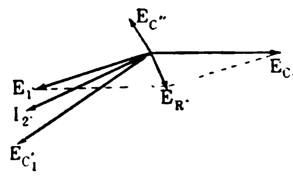

FIG. 16

Compensating of Frequency Disturbance. Since disturbances due to frequency variation may be used by any one of the methods mentioned in the foregoing paragraph, it is obvious that it should be possible, by the introduction of one or more of these causes, to compensate the existing disturbance in a particular location and arrangement of the whole detecting equipment. For example, out of a great number of combinations which were tried, the two following may be mentioned:

(a) Balancing C against a derived circuit on C', the characteristics of this latter circuit being so adjusted that the zero upset resulting from a small frequency change was as nearly as possible a minimum. This adjustment could be made by a cut and try method, using a definite frequency change in successive trials.

(b) With C and C' balanced as in the simple circuit of Fig. 18 to balance out their resultant with a derived electromotive force, the characteristics of

which were chosen so that the zero upset for a given small change of frequency was as nearly as possible zero.

An illustration of the type of circuit used for class (a) may be seen in Fig. 17, where C is balanced against an electromotive force across C and R. Fig. 18 shows a combination of the two, in which E_c is balanced against the resultant of E' and E_c''. Here it is possible to vary the effect of frequency on both the electromotive forces used to balance the electromotive force of C. E_1 is, in general, not in exact opposition of phase with E_c. The resultant of E_1 and E_c'' however may be brought into exact opposition.

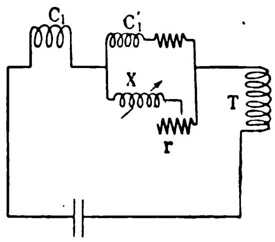

FIG. 17

These methods of eliminating a given frequency disturbance had two serious drawbacks:

(a) The amount of manipulation necessary to obtain the balance and

(b) The resultant balance, although independent of a frequency change of a given magnitude, still had a large zero disturbance in the final balanced position. The exact cause of this disturbance could not be found, but it is assumed that compensation for a frequency change of one amount is not necessarily effective for a frequency change of a different amount.

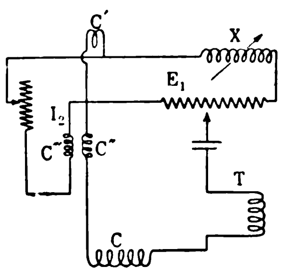

FIG. 18

Too conspicuous conclusions resulted from the work indicated in the foregoing; the first, the more complete the coincidence of phase in electromotive forces in C and C', the less the disturbance of the balance conditions by change in speed of the generator; and second, it is always possible to overtake an improvement in speed control by such increase in sensitivity as will still leave speed variations as a limiting factor to sensitivity of the detecting circuit.

Final Technique for Obtaining Balance. Since it is not possible to compensate all frequency variations, it appeared best to maintain the speed as nearly constant as possible and then adopt the simplest method available for bringing the electromotive forces in C and C' into exact opposition of phase. The two most satisfactory methods for speed control are described in Appendix B.

As already stated, the phase of the field due to the magnet lags more and more the greater the distance from the magnet. Unless therefore either C or C' is in close proximity to a large magnetic mass, it will be found that the phase of the electromotive force in C' leads that in C, since C', owing to its small size, is always nearer to the magnet. If now C' be shunted by a non-inductive resistance, the value of this resistance may be so chosen that the electromotive force at its terminals is exactly in phase with the electromotive force in C. The magnitude of the electromotive force at the terminals may be varied by rotating C' in the main magnetic field. Since C' and the shunt resistance may both be located within convenient reach on the observer's table, this appears as simple a method as may be found. Following are the successive steps in obtaining a balance by this means:

1. Set commutator for the maximum signal due to the electromotive force in the detecting coil C, by setting for zero deflection.

2. Shift the commutator brushes 90 deg. and balance out the electromotive force due to C by rotating C'.

3. Shift commutator back 90 deg. and balance out the residual by varying the resistance in shunt with C'.

4. Repeat (2) and (3) until the out-of-phase component is out and a good balance results.

Very often the proper value of shunt resistance may be found by noting the magnitude of the vibration, or "wiggle," of the galvanometer needle. A variation of the shunt resistance is reflected in the amplitude of this vibration. This method obviates the necessity of shifting the commutator away from the position (2), but is not as exact as the complete operation as described.

Ordinarily only a few minutes are required to make the complete balance adjustment, and once made a single adjustment is usually sufficient to rebalance after any upset of balance due to slow temperature changes.

Other Disturbances. The stability of the balance may be affected by a number of extraneous causes, and some of those encountered are mentioned below:

(1) Inductive disturbance from circuits and machines even at considerable distances from the detecting circuit. These disturbances could, in some cases, be neutralized inductively by placing a loop of the offending circuit in proper relation to the detecting circuit.

(2) Temperature changes often caused slow creeps of the galvanometer zero. These changes are usually present unless the whole equipment has been warmed up by a sustained period of operation.

(3) The harmonic residual always present in the

best balances appeared at maximum sensitivity as a vibration or shake of the galvanometer needle, quite different in appearance from the "wiggle" mentioned above. These disturbances may be eliminated by means of filters, or pilot conductors. (See Appendix A).

(4) Mechanical vibration of the amplifier. On shipboard this was completely obviated by spring suspension of the amplifier.

The many refinements of adjustment and elimination of disturbances, suggested in the foregoing paragraphs, were studied and used principally in the tests on shore. On shipboard the conditions, as regards mechanical vibration due to the engines and motion in the sea, became the limiting factor when the sensitivity was increased. Although, as stated, S. C. No. 326 was an unusually steady boat, it was nevertheless found that the changes in the relative position of the magnet, detecting and balancing coils, was the limiting factor; consequently, it was not possible to use the extremes of amplification and sensitivity that have been used on shore. Nevertheless, the care which had been given to the elimination of disturbances had resulted in such an improvement in the general makeup of the equipment that it was possible to use between three and four stages of amplification in increasing the sensitivity. This was approximately one stage less than used in the best shore tests, and consequently many of the refinements necessary in the latter tests for eliminating disturbances were not necessary on shipboard.

Other Forms of Balance. The foregoing discussion refers particularly to the arrangements *A* and *B* of Fig. 1. A number of other arrangements of the detecting coil were tried, but without noticeable advantage. One of these should be mentioned. The detecting coil is arranged with its plane parallel to the direction of the field of the main magnet. This arrangement is not practicable, by reason of the presence of the right-angle component of the rotating magnetic field. This component has to be balanced out and it appears to be extremely sensitive to frequency changes. It is possible that with further investigation and study this arrangement could be used. It has the great advantage that the electromotive force in the detecting coil is small and that therefore it can be balanced out by an electromotive force correspondingly small. Since the balance of large electromotive forces makes it correspondingly difficult to balance out their residual, it would appear that this method has some promise.

APPENDIX E

The Steel Hull as a Magnet

A serious limitation of the method of detection described in the body of this report is the requirement that the detecting vessel be of wooden construction. It is obviously highly desirable that any method of detection should be suitable for installation on a destroyer or other type of patrol vessel having a steel hull. The possibility of using the steel hull as the core of the magnet was suggested by Lieutenant-Colonel Mershon early in the investigation. A number of experiments were made at Johns Hopkins University on the submarine models which have been described in other parts of this report.

The models used have been described as S_x and S_y but in these experiments and the accompanying figures and curves they are designated D_{xx} and D_{yy}. A coil of 234

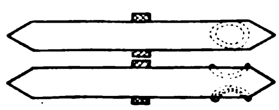

Fig. 19

turns of No. 10 B. & S. magnet wire was placed around the model at its center and excited with 80 volts, 30 cycles of alternating current. Experiments were made with D_{xx} in its original form and also after it had been slit longitudinally, *i. e.*, along one element through its entire length.

The detecting coils used were about 1 ft. in diameter and had 300 turns each. They were flexible so that they could be fitted closely to the sides of the model. In one arrangement two of these coils were balanced against each other, one being placed on each side of the model near the bow, as indicated in Fig. 19.

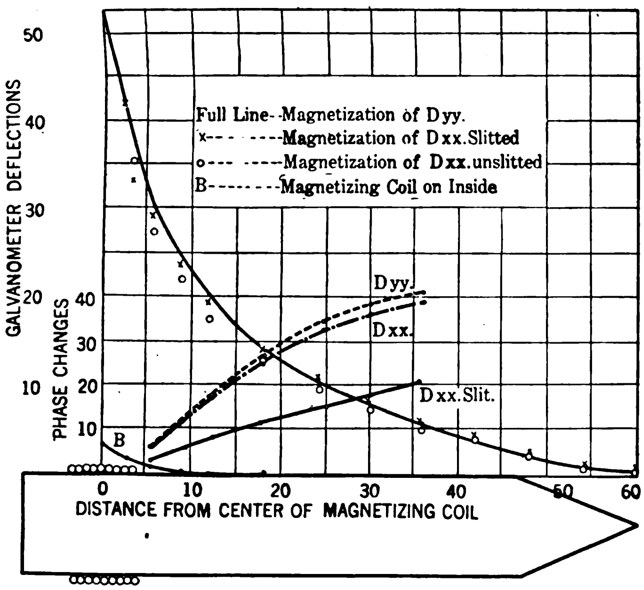

Fig. 20—Magnetization of Destroyer

The distribution of the magnetic flux over the length of the model is shown in Fig. 20, where the alternates represent the electromotive force in a test coil located at different positions along the length. The distribution is seen to be closely the same for models of different thickness and also for the model which was slit from one end to the other along one element.

An interesting and important feature, in its bearing on the use of the hull as a magnet, is the variation in

phase of the flux in passing along the length. The phase of the electromotive force in the exploring coil could be determined simply by the rectifying commutator and detecting instrument. The total variation in phase of the main flux passing from the magnetizing coil to the end of the model was found to be 46.5 deg. for D_{xx}, 23.4 deg. for D_{xx} slit, and 48 deg. for D_{yy}. This variation of phase is shown in the smaller curves of Fig. 20.

The serious limitation of the use of the hull as a magnet, as indicated by the experiments, is in the diffculty of maintaining a satisfactory balance in the

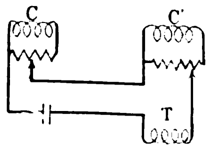

Fig. 21

detecting circuit. Several methods of balancing and disposition of coils were tried as follows:

1. With the coils in the position of Fig. 19, one or both coils were shunted with resistances, taps on which afforded the voltage changes required for balancing. (See Fig. 21, in which T is the primary of the transformer feeding into the amplifier and detecting instrument). The phase changes necessary were obtained by moving one or both of the coils lengthwise over the surface of the hull. With the coils in the positions shown in Fig. 19, this gave the best of all the balances studied in these tests.

2. The detecting coil was placed near the end of the destroyer in the position indicated in Fig. 22. In this

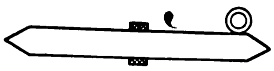

Fig. 22

case the attempt was made to set the coil parallel to the field and so obtain a minimum e. m. f. No position of zero e. m. f. was found and in fact the right angle component of the rotating field was so great that it was not possible to secure a balance in this way.

3. An attempt was made to balance a coil placed round the bow of the destroyer against portions of one placed at the center. It seemed possible that the submarine to be detected might cause a variation of some magnitude in the normal balance of two such coils. The arrangement was not practicable, however, on account of the serious phase difference between the electromotive forces in the two coils.

In all cases it was tedious to obtain a workable balance. The great difficulty was found to lie in the rapid variation of phase as between different positions of the coil along the side of the hull. If the position of the coil was varied to correct for phase difference, a large magnitude difference was introduced at the same time. The best balances which were obtained were very sensitive to variations of frequency and were, in general, less satisfactory than those pertaining to the experiments with a magnet having laminated core and

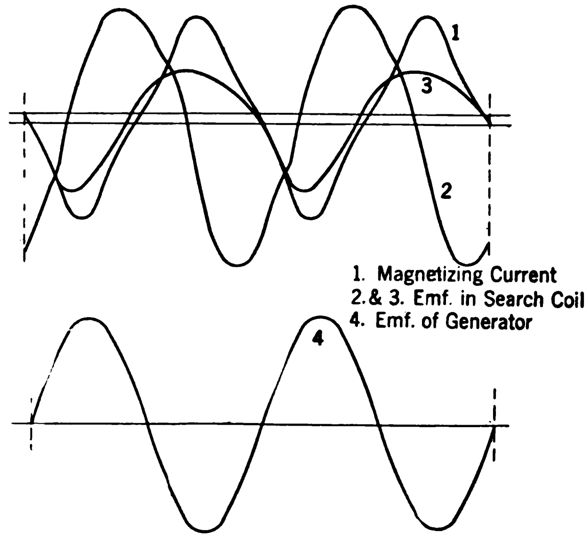

Fig. 23—Oscillograms of Destroyer Field

distributed winding. The balance was found to be extremely sensitive to changes of temperature. Due to eddy currents the temperature of the hull of the model rose considerably to the center, tapering off towards the ends. A glass of water thrown on one side of the hull caused a violent upset of the balance.

A part of the trouble with the balancing was found to lie in the presence of harmonics in the electromotive forces in the detecting circuit. Fig. 23 shows in curve 1 the magnetizing current, curve 2, the electromotive force in the exploring coil when placed around the hull

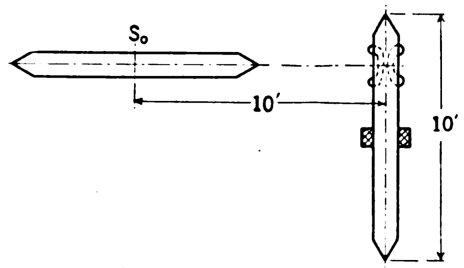

Fig. 24—Relative Positions of Destroyer and Submarine

near the magnetizing coil, and curve 3 the electromotive force in the exploring coil when flattened against the side of the model near the bow. Curve 4 shows the electromotive force of the generator. These curves were all closely copied from oscillograms. In the experiments the harmonic components present were eliminated by the use of a filter.

On account of the difficulty in balancing, the maximum sensitivity in amplifier and detecting instrument could not be used. A number of rough detection

observations were taken, however, of which the most promising were in the relative positions shown in Fig. With S in the position shown, and 10 ft. between centers and detecting coils flattened against the side, the following readings were obtained:

With D_y	30 divisions
With D_y	20 divisions

Using the 2000-turn coil, C_1, as used in the experiments with the magnet, the coil being set parallel to the field on the deck of the destroyer, as shown in Fig. 22, with S at 10 ft., the deflections were for D_{zz} 35 divisions, and D_{yy} 50 divisions.

The experiments with the magnetized model appear not to offer any very great promise for the use of this method. It is probable that the most promising direction in which further study of the method could be made would be in a more uniform magnetization of the hull by, applying additional coils further away from the center, and working the hull at a much lower flux density. In this way there should be less trouble with differences in phase in the balancing coil and also less possibility of disturbances due to temperature variations. It is also certain that the problem of balancing would be very greatly facilitated by the use of a variometer by which the electromotive force in the detecting coil could be balanced, thus obviating the necessity of obtaining a balance by moving a balancing coil.

APPENDIX G

Magnets and Coils

Magnet M_1. This magnet, used in the laboratory tests at the Johns Hopkins University, has been described, and the general method of applying the exciting winding is shown in Fig. 5. The purpose of the multiple winding is to increase the effective length of the magnet and, as far as possible, to prevent variations in this effective length with variation of frequency and voltage.

The distribution of flux in this magnet is indicated approximately in Table 4, in which the first column gives the distance of an exploring coil from one end of the core, and the second column the corresponding voltage induced in this coil. The figures show that the flux is fairly uniform over the whole length of the core, falling off rapidly, however, for positions outside the ends of the magnetizing winding.

Magnet M_2. This magnet was designed by the manufacturer, to give the largest possible magnetic moment with an excitation of 26 kv-a. at 30 cycles. It has a distributed winding with multiple connection of the same general character as that of magnet M_1, the number of coils, however, 266, being much greater. Data as to the number of turns, size wire and dimensions of the respective coils have not been given by the manufacturer. The whole winding is imbedded in weather-proof compound with protective covering.

The pole pieces of the core are relatively longer than in the earlier magnet M_1, thus reducing the amount of copper necessary in the end coils. The laminated core is built up around a wooden cylinder and the cross section of iron is not given. The outside diameter of the combined wooden and iron core, which is circular in cross section, is about 1 ft. The completed magnet is mounted on saddles in a strong and rigid wooden frame.

TABLE IV
DISTRIBUTION OF MAGNETIC FLUX IN MULTIPLE WOUND MAGNET M_1

Distance from one end—inches	Volts in exploring coil
1	3.22
6	5.05
11.2	4.80
15.7	4.90
22	4.84
27.7	4.84
33.5	4.84
39.2	4.70
45.2	4.75
51.2	4.71
58.2	4.70
61.7	4.82
65.7	4.95
71	2.95

Additional data on Magnet M_1 are given in Table 5.

The electric and magnetic constants are given in Table 5.

Magnet M_3. This magnet differs from magnet M_1 principally in its relatively longer pole pieces, the object being to still further reduce the excitation required. As a result, this magnet required a smaller kv-a. consumption and had a greater magnetic flux and magnetic moment than M_1. Its length was about as great as could be comfortably handled in various positions on the deck of S. C. No. 326.

Detecting and Balancing Coils. The data pertaining to the three detecting coils used in the three main divisions of the work are assembled in Table 6. The largest coil C_2, was built by the Westinghouse Electric & Mfg. Co. and was rigidly mounted in a wooden

framework. The winding was thoroughly water proof and enclosed in a protective wooden covering. This coil was designed for out-of-door service.

The detecting coil, C_3, was located in the small forehold of the chaser. This coil had to be wound by hand, its wooden form having been constructed outside and then assembled in place. Owing to the limited space, the winding of this coil was a tedious matter. However, when completed the substantial wooden form and its proximity to the timbers forming the frame of the ship offered a ready means for thoroughly bracing it in position. It contained approximately 900 lb. of No. 13 double cotton-covered magnet wire and was suitably protected against moisture and damage.

A variety of balancing coils was used in different stages of the work. In the experiments in the laboratory and on S. C. No. 326 three coils were used, all having the same dimensions as those of detecting coil C_1, but having 2000, 1000 and 306 turns, respectively. The balancing coil C_2' was of special weather-proof construction, as described for detecting coil C_2. It was three feet in diameter and had 530 turns. It was provided with a worm gear for rotation about a diameter as a vertical axis and also had a gear for a short rectilinear translation. Both of these features were for the purpose of accurate adjustment in balancing. All metal parts were of brass and the entire coil with its adjustment was mounted in a substantial wooden framework.

APPENDIX H

DETECTING AND MEASURING INSTRUMENTS

In the early stages of the work, when sensitivity was a desideratum, suspension-type D'Arsonval galvanometers were used as detecting instruments. It was realized, however, that such an instrument could not be used on shipboard, and as soon as the amplifying equipment was available, the instruments were abandoned. At one time the commutator was suspected as a possible seat of troubles in balancing the detecting circuit. A unipivot type of electro-dynamometer was therefore tried for direct measurement of the signal in the detecting circuit as an alternating current. Experiments with this instrument, however, gave indication that the disturbances in question were due to other causes. Furthermore, the sensitivity of the electro-dynamometer was lower than that of the most suitable D'Arsonval instrument available and offered certain difficulties in the process of balancing and detecting circuit, notably the steps necessary for eliminating the residual or out-of-phase component.

A further effort in the direction of increased sensitivity without the commutator was made in a series of experiments, using an Einthoven string galvanometer. The aim here was to reduce, as far as possible, the number of stages of amplification necessary. Two strings were furnished with this instrument, one of silver and the other of silver quartz. The extreme value of 3.5 times 10^{-16} watts direct current per division of sensitivity was claimed for the instrument using the quartz string.

As compared with the commutator and continuous-current galvanometer, the Einthoven string galvanometer is subject to the following limitations: With the former combination, in the process of balancing, any out-of-phase residual which may be left in the detecting circuit is chopped up by the commutator and appears, if at all, only as a slight vibration of the needle in its zero position. The same statement may be made with reference to any harmonic disturbances which may be present. With the string galvanometer, both the residual and the harmonic will produce a vibration of the string in exact proportion to their intensities. In the experiments with the string galvanometer, these residuals are necessary to produce deflections equal to that pertaining to a strong signal, this sets a definite limit to the sensitivity that may be used with the string galvanometer. A number of rough detection experiments were made, but it was found that the limits mentioned resulted in very much lower distances of detection than found in the case of amplifier, commutator, and continuous-current galvanometer. There remains the possibility of filtering out the harmonics using one or two stages of amplification, and so making use of the extreme sensitivity of this type of instrument. However, it appears probable that the process of balancing would have to be accomplished with the use of other equipment and there is always the question of the behavior of such an instrument on shipboard.

Two instruments of special type were constructed by the Weston Electrical Instrument Co. They were described as Weston No. 2 and No. 3. Instrument No. 2 was found to be not suitable on account of the delicacy of its suspension. Instrument No. 3 was designed especially to dampen out, as far as possible, irregular motions of the galvanometer needle in its position of balance. This instrument, therefore, was heavily damped and its moving part had a relatively high moment of inertia. The weight necessary, and

the consequent force per unit area on the bearings, puts a low limit to the moment of inertia of a sensitive pivot coil instrument; consequently, in this instrument an attempt was made to improve the balance conditions by the use of high and variable damping. This was accomplished in the two-pivot special Weston galvanometer No. 3, by electromagnetic excitation of its field. The instrument had the following characteristics:

Sensitivity,	5.7×10^{-8} amperes per division
Moment of inertia of coil,	2 g. cm.[2]
Undamped period,	1.65 seconds
Interval shunted with 80,000 ohms,	7 seconds
Interval when connected to last stage of amplification and with field fully excited,	80 seconds

By sacrificing some sensitivity, the extremely long interval mentioned, when connected for testing, could be reduced by reducing the field excitation. For the same sensitivity of detection the instrument could be used with one stage of amplification less than that pertaining to the instrument which was used for practically all the other tests. It showed no other decided advantage over the latter instrument which is described below. The possibility of using one less stage of amplification offers some advantage and the instrument was used in a large number of tests. However, it was not as rugged as the instrument next to be described and which supplanted the Weston instrument in all of the later tests on shipboard.

Best Form of Detecting Instrument. The most satisfactory detecting instrument of all was a Siemens & Halske, double-pivot, D'Arsonval type, portable needle galvanometer. This instrument had a central zero and a complete scale of 25 one-millimeter divisions on each side. Its resistance was 100 ohms and its sensitivity 10^{-6} amperes per division. Its critical damping resistance was 90 ohms. This galvanometer withstood all the hard usage of over a year of experiment, and was continuously subjected to various forms of accidental unbalancing, resulting in excess currents, and to the many extreme manifestations of "wiggles" and "shakes" of the needle arising from unforeseen unbalanced resultants, harmonics and extraneous disturbances amplified several hundred times. It had a clear and open scale for direct reading and was in every way superior to all other instruments tried, from the standpoint of convenience and rugged construction. At the end of the experiments its sensitivity was found by test to be unimpaired. Efforts were made to find an instrument of the same general type which would have a higher sensitivity, but when increased sensitivity was found it developed that it was at the sacrifice of either length of scale or substantial construction.

Telephone Receiver as Detector. A number of tests were made with telephone receivers in place of the commutator and galvanometer. Obviously 30 cycles is too low a frequency for audibility. Consequently in order to use the telephone receiver it is necessary to interrupt at sufficiently high frequency the current constituting the signal from the detecting circuit. This was accomplished by placing in series with the telephone instrument at the output end of the amplifier a "chopper," the speed of which could be adjusted for any desired pitch tone for the telephone. Three different forms of chopper were tried, (a) simple interrupter, (b) condenser chopper with sliding contacts and (c) condenser chopper without sliding contacts. All were relatively small machines driven by direct-current motors of variable speed. No further description of these choppers need be given here, as no promising results were obtained from any of them. The invariable trouble was that even at low sensitivity, as regards amplifier and detecting instrument, it was found practically impossible to balance for zero noise in the receiver. Moreover, it was found that under best conditions as to quietness, the electromotive force in the detecting circuit necessary to give a signal was considerably in excess of that required to give a full scale deflection on any one of the galvanometers as detector.

No special study was made of the characteristics of the telephone receiver itself, but four or five different receivers collected from the laboratory telephone and radio equipments were tried. The fact that it was found impossible to eliminate sound in the balanced condition, even with low sensitivity equipment led to the conclusion that this was not the most promising direction in which to look for a higher sensitivity. Moreover, the telephone has in common with the Einthoven galvanometer the disadvantage that it needs an auxiliary equipment for balancing, nor does it give a quantitative indication.

CHEAP WIRELESS TALK ACROSS OCEAN

Signor Marconi prophesies that in the immediate future conversations between Great Britain and the United States will be carried on by wireless telephones and that the price will not be more than 14 cents for one minute.

The great inventor said that he spoke direct to Canada from London and he added:

"It is only a matter of time when we shall be able to talk to New York from London. Already we have carried out many successful experiments between London and the Continent, and we hope that we shall be able soon to announce the installation of a world-wide wireless telephone system in all countries interested. Our plans are developing rapidly."

Transoceanic conversations will be carried on through an ordinary telephone, the exchange being connected with the wireless stations at the receiving end and the same methods will be followed.

Signor Marconi already has applied for permission to erect a station in Norway to demonstrate his ability to talk across large expanses of water.—*Telephone Engineer.*

Magnetic and Electrical Properties of Iron-Nickel Alloys

BY T. D. YENSEN

Research Metallurgist, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Part I. This investigation was undertaken to determine whether any iron-nickel alloys could be found having a higher saturation value than pure iron. Alloys were prepared containing 0-100 per cent Ni.

Pure Fe-Ni alloys do not forge readily, and to make them forgeable it is necessary to add alloying elements like Mn or Ti.

The results show that the saturation value decreases slowly with increase in Ni content up to 20 per cent Ni; then rapidly to 30 per cent; again rises rapidly to 50 per cent and falls off gradually toward 100 per cent Ni. At no point does it exceed that of pure iron.

For values of H between 100 and 400 the permeability is about 5 per cent higher for 6 to 8 per cent Ni than for pure iron, but this advantage is offset by the large increases in hysteresis loss.

Alloys containing 35 to 70 per cent Ni have high permeability at low and medium densities and low hysteresis loss, the highest permeability occurring for 50 per cent.

30 to 50 per cent alloys are characterized by a nearly straight line B-H curve from the origin to B = 2000 to 4000 gausses and also by low retentivity and coercive force, properties which are of value in connection with certain electromagnetic meters.

Part II. Previous investigations on commercial iron-nickel alloys have shown that 25 to 35 per cent alloys have irreversible magnetic and electrical transformation points occurring below ordinary temperatures. The present investigation confirms these results for pure alloys. A 30 per cent alloy, annealed and cooled to room temperature, had its saturation value, $4\pi I_s$ increased from 2500 to 17,800 gausses and its electrical resistance decreased from 81 to 32 microhms per cu. cm. after being cooled to liquid air temperature and reheated to room temperature. Alloys containing 15, 35 and 50 per cent nickel showed practically no change after the above treatment. After allowing all transformations from the austenitic state to the α state to take place the curves for $4\pi I_s$ and for electrical resistances both have definite cusps for 34.5 per cent nickel, corresponding to the compound Fe_2Ni, thus giving evidence of the existence of this compound. It is pointed out that the irreversible transformation causes an enormous increase in the hysteresis loss.

PART I

Introduction. The discovery of materials having higher magnetic saturation than pure iron is of great importance in connection with dynamo-electric machinery, because it is the saturation value of the material in the teeth of the armature that determines to a large extent the size of the machines. If the saturation value could be raised 10 per cent, this would mean that the length of the armature—and consequently the field and frame—could be decreased by approximately 10 per cent, with a resultant large saving in the cost of the machine. Cobalt has been known for some time to increase the saturation value; in the case of the alloy Fe_2 Co by as much as 10 to 13 per cent[1]. At high inductions the author has shown[2] that the permeability of Fe_2 Co may be as much as 25 per cent higher than that of pure iron. This alloy would therefore seem to be very suitable for the purpose mentioned were it not for its high cost. Efforts have consequently been made to discover less expensive materials with properties similar to those of Fe_2 Co.

Nickel has been suggested as a possible substitute for Co, in spite of the fact that according to Weiss[3] nickel lowers the saturation value of iron. Burgess and Aston[4] prepared a large number of alloys ranging from 0–100 per cent Ni and among these there were one or two alloys having a slightly higher permeability at high inductions than pure iron. The composition of these alloys was in the neighborhood of 5 per cent Ni. These results and certain others obtained with low nickel steels prepared commercially made it desirable to investigate carefully the possibilities in the direction indicated. Alloys were consequently prepared from the purest materials obtainable and by the most approved method known to yield pure alloys.

Preparation. The alloys were made by melting the desired proportions of electrolytic iron and electrolytic nickel placed in magnesia crucibles in an Arsem type vacuum furnace under pressure of 1 to 2 mm. mercury. Chemical analysis of the above materials gave the following results:

Element	Electrolytic Iron	Electrolytic Nickel
S	0.003 per cent	0.006 per cent
P	Trace	0.001
C	0.014	0.030
Mn	Trace	Trace
Si	Trace	0.040
Cu	Trace	.....
Al	0.005	.....
Fe	99.978 (by diff.)	0.250
Ni	.....	99.673 (by diff.)

The first attempts that were made to forge the ingots

revealed the fact that pure iron-nickel alloys do not forge very well at ordinary forging temperatures. Up to 8 per cent Ni, and in rare cases with higher nickel contents, fairly good forgings were obtained by forging at a dull red heat, but not by forging at a bright red heat. In other cases the alloys would forge at a black heat, or even cold, while some alloys could not be forged under any conditions. In order to obtain

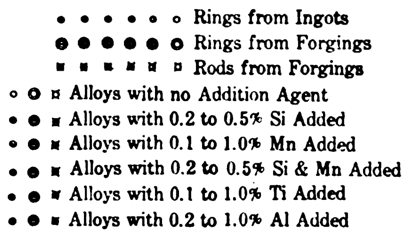

Fig. 1—Key to Point-Notation of Iron-Nickel Alloys

pure iron-nickel alloys in the form of test pieces it was, therefore, necessary in some cases to machine rings directly from the ingots. Forgeable alloys were obtained by means of certain addition agents. Ti and Mn worked successfully for this purpose, while Si, Al and Mg had no effect. The amounts of Ti and Mn required varied from 0.2 per cent for 10 per cent Ni to 1.0 per cent for 50 per cent.

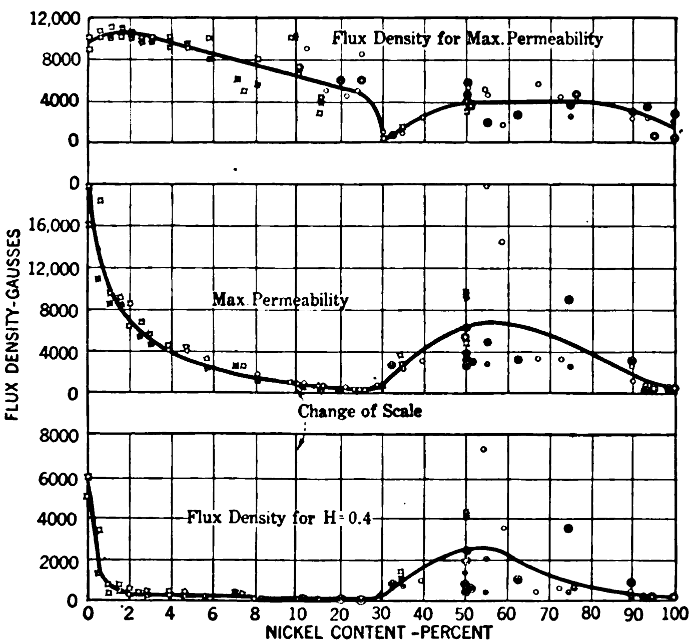

Fig. 2—Flux Density for Maximum Permeability

Three kinds of test pieces were prepared:

1. Rings from ingots, 2.46 cm. (31/32 in.) outside diam., 1.83 cm. (23/32 in.) inside diam. and 0.95 cm. (3/8 in.) long.

2. Rings from forgings, 2.46 cm. (31/32 in.) outside diameter, 1.83 cm. (23/32 in.) inside diameter and 0.95 cm. (3/8 in.) long.

3. Rods from forgings 1.27 cm. (1/2 in.) diam. and 30.5 cm. (12 in.) to 35.5 cm. (14 in.) long.

The annealing was done at 900 to 950 deg. cent, in rare cases at higher temperatures, in a vacuum furnace, under a pressure of less than 0.1 mm. of mercury, the test pieces being buried in granulated MgO, and the temperature measured by means of a Pt-Pt Rh thermo couple. The cooling was extended over a period of 24 hours and was done at a rate of approximately 30 deg. per hour.

Testing. The magnetic testing of the rods was done by the Burrows compensated double bar and yoke

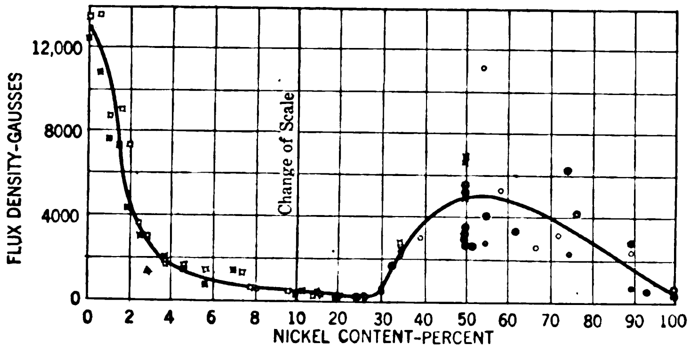

Fig. 3—Flux Density for $H = 1$

method,[5] being the most approved method thus far developed for rods. The rings were tested by means of the ordinary two-winding method, no other method being either simpler or more accurate.

Results. The results are embodied in the following tables and curves. No attempt has been made by means of separate curves to show the effect upon the properties of pure iron-nickel alloys by the addition of other elements necessary to make them forgeable.

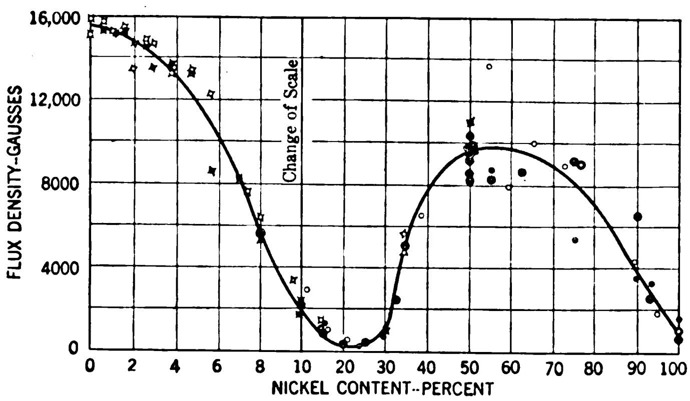

Fig. 4—Flux Density for $H = 4$

In most cases the effect of nickel upon iron is so marked as to obscure any effect due to other elements. Only in the region from 50–70 per cent are the alloys markedly susceptible to mechanical and heat treatment and to other alloying elements, and in this region there is much uncertainty as to the magnetic proper-

ties at low flux densities. This is plainly seen in Figs. 2, 3, 4 and 10 for maximum permeability, for permeabilities for H = 0.4, 1 and 4, and for hysteresis loss, respectively. In spite of this uncertainty all points have been plotted together and the curves

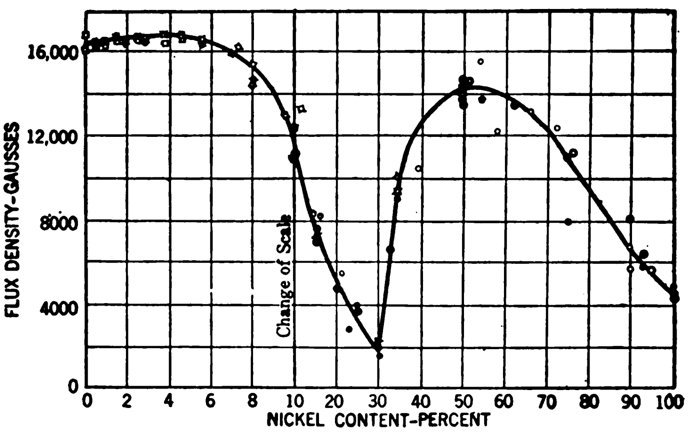

FIG. 5—FLUX DENSITY FOR H = 20

drawn through the centers of density of the point. The curves thus obtained for H = 0.4, 1, 4, 20, 100, 400 and for the saturation intensity, $4\pi I_s$, have all been replotted in Fig. 9 showing at a glance the variation in permeability for various magnetizing forces with variation in nickel content. These curves might be termed the magnetic iso-gilberts for the iron-nickel alloys. To this set of curves the following general statements can be applied:

1. The saturation intensity, I_s decreases slightly—not more than 1 or 2 per cent—from pure iron to 20

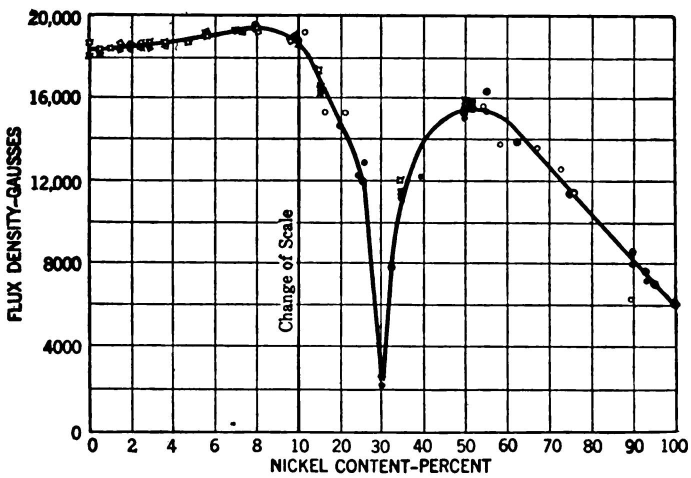

FIG. 6—FLUX DENSITY FOR H = 100

per cent nickel. Between 20 and 30 per cent nickel I_s decreases to one-tenth of its previous value, increases again rapidly beyond 30 per cent, reaches a maximum for 50 per cent nickel and finally decreases

gradually toward 100 per cent nickel, the value for pure nickel being between 1/3 and 1/4 that for pure iron.

2. The iso-gilberts for high values of H are of the same general shape as that for I_s, except that there is a slight increase—about 5 per cent—in permeability between O and 8 per cent nickel.

30 per cent nickel has been shown to be due to the fact that the magnetic transformation point of these alloys lies below ordinary temperatures. K. Honda in a recently published paper[6] has shown that cooling the alloys in liquid air and then heating them to room temperature raises I_s from the minimum value of about 200 to nearly 1000. At the same time the

1. As per Chem. Anal. other alloys as per amount added.
2. C—0.061 per cent not plotted.
3. For $\beta = 2,000$
4. For $\beta = 4,000$
5. For $\beta = 6,000$
6. For $\beta = 8,000$

3. For low values of H the iso-gilberts drop rapidly from pure iron and remain very low until the 30 per cent point has been passed; reaching a maximum between 50 and 60 per cent nickel, for which in some cases a permeability has been reached approaching that for pure iron; and finally decreases to very low values for 100 per cent nickel.

The low saturation value occurring in the region of minimum point has been shifted from 28 to 30 per cent to about 34.5 per cent, the latter corresponding to the compound Fe_2Ni.[7]

6. The Thermal and Electrical Properties of Nickel Steels, *Sci. Repts.*, Tohoku Imp. Iniv. 7, pp. 59–66. (1918).

7. By the above treatment the iso-gilberts would, of course, also be changed, and the entire set of curves would appear very differently. This matter is discussed in Part II of this paper.

1. Per cent Ni added, alloy not analysed chemically.
2. For $\beta = 4{,}000$
2. For $\beta = 1{,}500$

Fig. 10 shows the variation of hysteresis loss for B = 10,000 gausses with nickel content. As might be expected from the iso-gilberts of the previous curve, the loss increases rapidly even with small additions of nickel, and the loss becomes very high for alloys containing 15 to 25 per cent, reaching a maximum of nearly 50,000 ergs per cu. cm. per cycle for the 25 per cent alloy. Between 30 and 70 per cent the loss is as low or even lower than for pure iron, but above 70 per cent the loss again increases rapidly reaching 20,000 for pure nickel.[8]

Fig. 10 shows the retentivity to decrease with increasing nickel content reaching a minimum of only 200 for the 30 per cent alloy. With further increase in nickel content, the retentivity again increases, reaching a maximum between 50 and 60 per cent nickel.[9]

Fig. 12 shows the variation in electrical resistance checking very closely the results obtained by Burgess and by Honda.[10] The curve has been drawn through the points for pure iron-nickel alloys for all cases in which alloys were available in the form of rods. In every case it will be noticed that the alloys containing a small amount of silicon have a decidedly higher resistance than the alloys without silicon, as

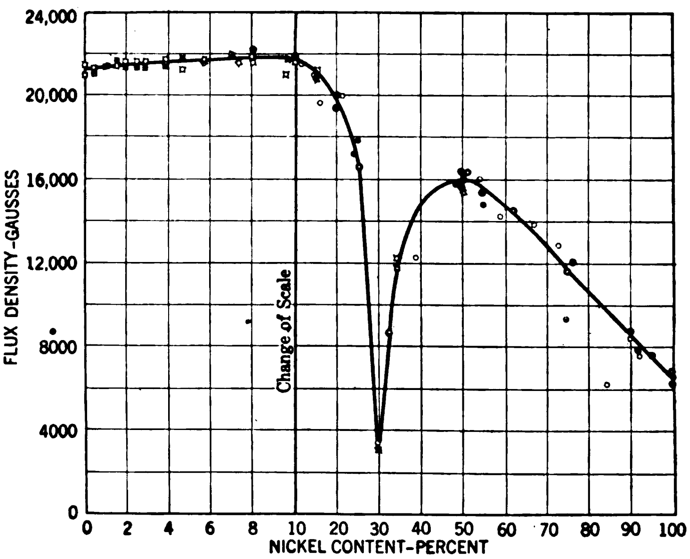

FIG. 7—FLUX DENSITY FOR H = 400

might be expected. The curve reaches a maximum for 30 per cent nickel corresponding to the composition of the alloy having the lowest magnetic saturation value. Honda has obtained a decrease in electrical resistance corresponding to the increase in the saturation value above referred to, by cooling the alloys in liquid air and then heating to room temp-

8. All losses are based on a flux density of 10,000 gausses. In case of the 30 and 80 to 100 per cent alloys having saturation values lower than 10,000 the losses were obtained for as high densities as possible, and the hypothetical loss for 10,000 calculated by means of the formula

$$W_{10} = W_B \left(\frac{10{,}000}{B} \right)^{1.6}$$

Where W_B is the loss actually obtained by test for the flux density B. The 1.6 law may not be strictly applicable in the case of the alloys mentioned, but is believed to be sufficiently accurate for the purpose of comparison.

9. No correction has been made in case the alloy was tested at a lower density than 10,000, but the error is supposed to be small in every case. Examples: 2 Ni 285, containing 75 per cent nickel was tested at 10,000 gausses, showing a retentivity of 2350, while 2 Ni 290, having the same nickel content, tested at B = 4000 gave a retentivity of 2550.

10. Loc. Cit.

erature. For the 30 per cent alloy the resistance decreased from a value of approximately 90 to 30 microhms, whereas no change is shown for the 34.5 per cent alloy corresponding to Fe_2Ni, making this the alloy having the maximum resistance.[11]

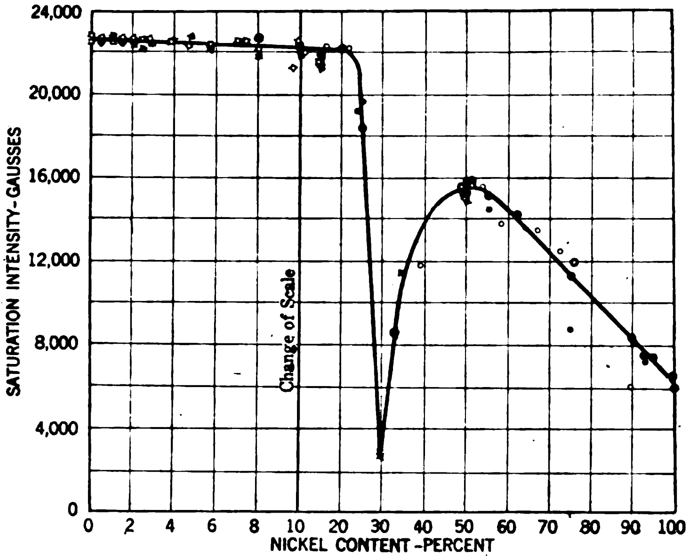

FIG. 8—SATURATION INTENSITY $4\pi I_s$ AND FLUX DENSITY FOR VARIOUS MAGNETIZING FORCES

The specific gravity shown in Fig. 13 was obtained incidentally as a means of obtaining the true cross section of the ring test pieces. The values increase uniformly from 7.9 for pure iron to 8.9 for pure nickel.

PART II

MAGNETIC AND ELECTRICAL PROPERTIES OF IRON-NICKEL ALLOYS REVERSIBLE AND IRREVERSIBLE TRANSFORMATIONS

Introduction. In Part I of this paper it was pointed out that the properties of alloys in the neighborhood of 30 per cent nickel would be very different after being cooled to liquid air temperature from after being cooled merely to room temperature. It was further pointed out that this difference is due to the fact that these alloys—in addition to the reversible transformation point occurring above room tempera-

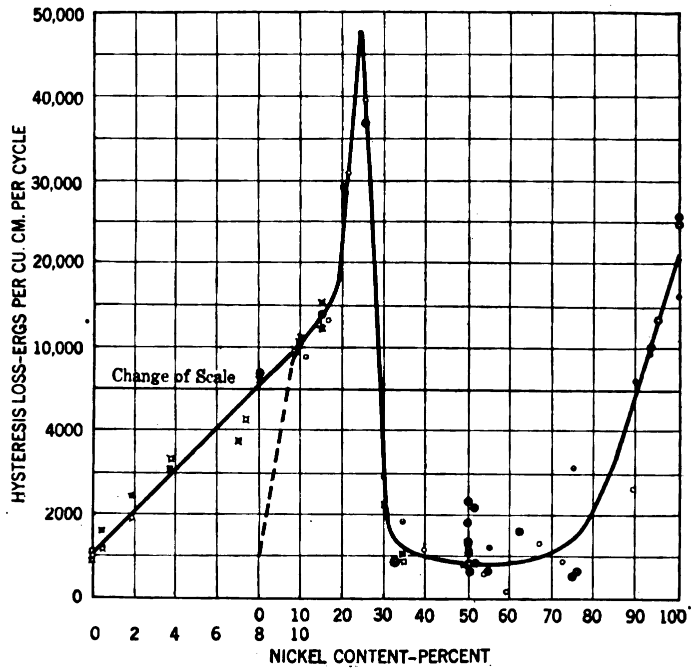

FIG. 10—HYSTERESIS LOSS FOR B = 10,000

ture—have an irreversible transformation point occurring below room temperature. These transformations have been studied a great deal in recent years, the pioneers in the field being Hopkinson (1), LeChatelier (2), Osmond (3), Guillaume (4) and Dumas (5).[12] The alloys investigated by these scien-

tists all contained foreign elements to some extent, particularly carbon and manganese. As a matter of fact manganese was considered an essential constituent, because without it, the alloys could not be forged. It is very unfortunate, however, for the interpretation of the results of the above investigations that these two elements referred to are the ones that affect the transformation points the most. Thus

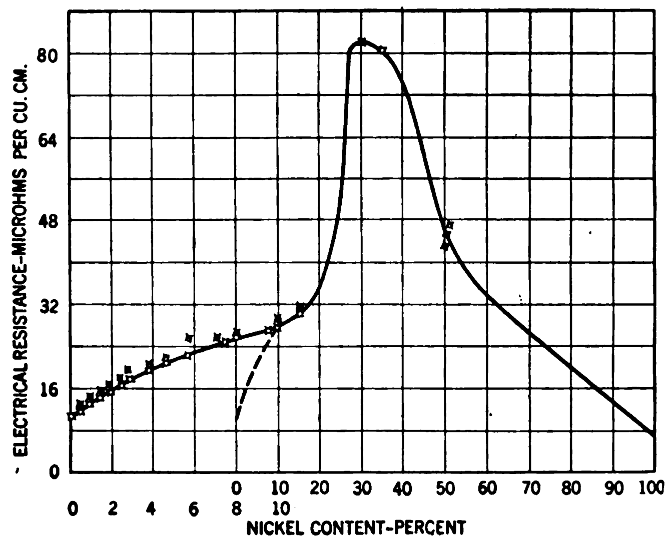

Fig. 12—Electrical Resistance

carbon is 20 times as effective as nickel in lowering the transformation points, and manganese, while less effective in this respect than carbon, still is much more effective than nickel. Dumas[13] realized this

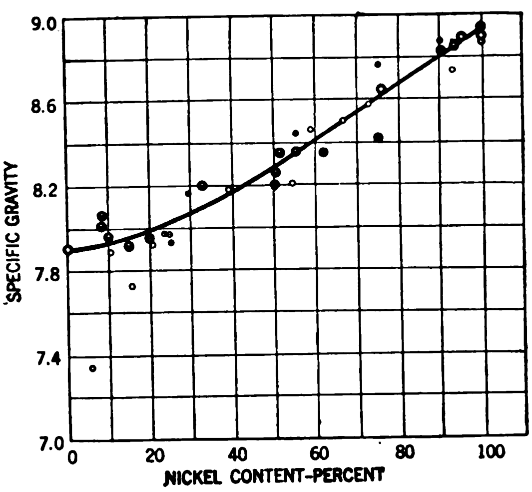

Fig. 13—Specific Gravity

when he stated that "No nickel steel is non-magnetic at ordinary temperatures except steels containing carbon and manganese," and he consequently attempted to keep these elements as low as possible. The results of his experiments are shown in Fig. 14. It will be noted that from 27 to 31 per cent nickel Dumas found both reversible and irreversible transformations.

13. Loc. Cit.

Of the two, however, the irreversible was by far the more intense. The broken curves indicate probable transformations in pure alloys that are too feeble in comparison with the transformations that have already occurred to be readily detected. However, by introducing carbon into the alloys, the irreversible transformation points may be lowered sufficiently

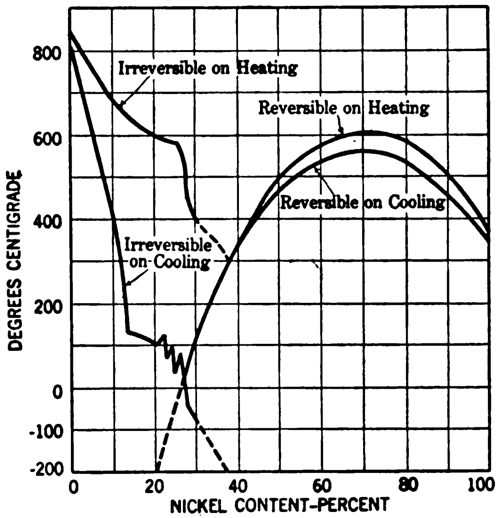

Fig. 14

without lowering the reversible points, to reveal the latter. Dumas cites the example of a 23 per cent alloy, which when pure has an irreversible point on cooling at +75 deg. but apparently no reversible point. By adding 0.85 per cent and 1.41 per cent

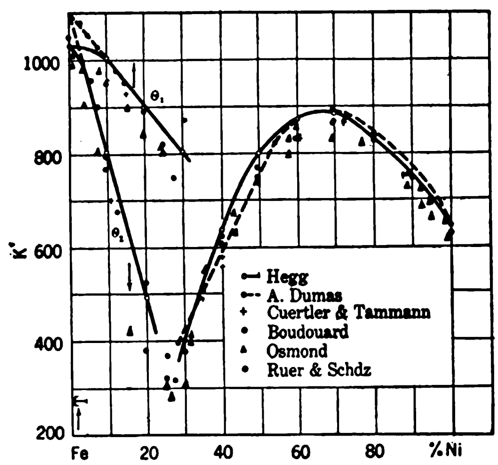

Fig. 15—Absolute Centigrade Temperatures of Magnetic Transformation (Curie Points) for Pure Ferronickels (Hegg)

Mn to this alloy the irreversible point is decreased to −188 deg., and on cooling from 0 deg.—the alloy is now non-magnetic—the reversible point is revealed at −150 deg. On the assumption that the reversible points are unaffected by C or Mn, Dumas concludes that the pure Fe-Ni alloys between 20 and 37 per cent nickel have both reversible and irreversible transformation points.

15. The Thermal and electrical properties of Nickel Steels *Sc. Reports* Tohoku Imp. Univ. 7, p. 59, 1918.

and electrical properties of nickel steels at ordinary temperatures and after quenching in liquid air. The latter treatment caused remarkable changes in the region of 25 to 30 per cent nickel, but no appreciable changes for other nickel contents, thus confirming the results already referred to. The results are shown in Figs. 17 and 18. On account of the foreign elements present in Honda's steels it seemed desirable to repeat his tests with pure alloys, and thus round out the investigation of the iron-nickel alloys covered in Part I.

Procedure. The samples used were selected from those used in the previous investigation, the prepara-

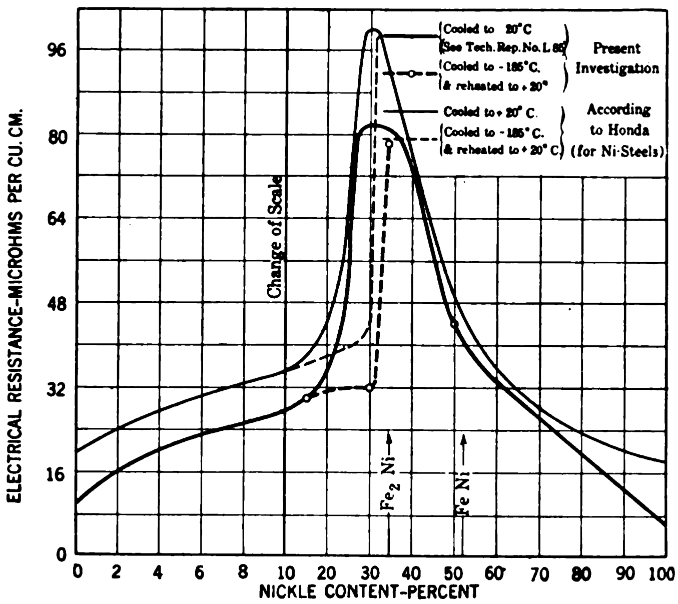

Fig. 18

tion of which is fully described in Part I. The test pieces used are as follows:

2 Ni 225—15 per cent Ni, 2 Rods 1.27 cm. (½ in.) diameter.
2 Ni 232—30 per cent Ni, 2 Rods as above and I ring 3.83 cm. (1½ in.) inside diam. and 4.47 cm. (1¾ in.) outside diam.
2 Ni 233—34.5 per cent Ni, 1 Rod and 1 Ring as above.
2 Ni 234—34.5 per cent Ni, 1 Rod and 1 Ring as above.
2 Ni 261—50 per cent Ni, 1 Rod and 1 Ring as above.
2 Ni 262—50 per cent Ni, 1 Rod and 1 Ring as above.

As a preliminary the rings were tested successively at room temperature, in CO_2 snow (– 70 deg. cent.), again at room temperature, then in liquid air (– 180 deg. cent.) and finally at room temperature. Then the rods were tested at room temperature, after having been cooled to – 70 deg., and after having been cooled to – 180 deg. The cooling to – 70 deg. was done by immersing the test pieces in gasoline, gradually adding CO_2 snow until no more would melt and maintaining the temperature for about half an hour by adding more snow from time to time.

Results. The results are tabulated in Table IV and shown graphically in Figs. 16, 17 and 18. It will be noted that while there is practically no change in the properties of the 15, 34.5 and 50 per cent alloys the 30 per cent alloy has undergone a marked change. Its saturation value, $4 \pi I_s$, was increased from 2700 to

Fig. 19—2 Ni 232 30 Per Cent Ni Cooled to Room Temperature. (100 Diameters)

14,600 by cooling to – 70 deg. and to 17,800 by cooling to – 180 deg. Similarly, the electrical resistance was decreased from 82 to 38 and to 32 by the above treatments. It is probable that the change would have gone to completion at – 70 deg. if the

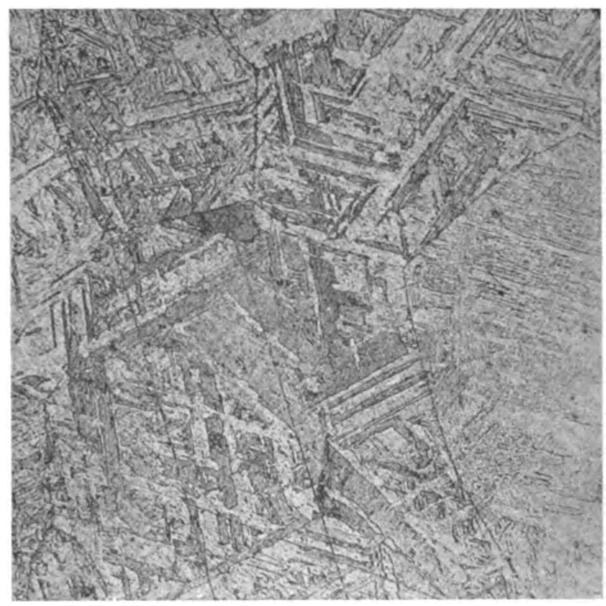

Fig. 20—2 Ni 232 30 per cent Ni Cooled to —70 deg. cent. and Reheated to Room Temperature. (100 Diameters)

testpiece had been held there sufficiently long and that the irreversible transformation point therefore lies between O and – 70 deg. thus confirming Dumas' results.

While only a few points were determined, they are sufficient to demonstrate that the cusp of both curves, after the completion of the transformations, occurs for approximately 34.5 per cent nickel instead of for 30 per cent as the previous investigation would lead one to believe. This points strongly towards the existance of the compound Fe_2Ni, corresponding to 34.6 per cent nickel, suggested by earlier investigators. The existence of the compound FeNi corresponding to 51.5 per cent nickel, is more doubtful, because there is no definite indication of it in the electrical resistance curve.

It is interesting to note that while the saturation value of the 30 per cent alloy was increased to a remarkable extent by being cooled to below the irreversible transformation point, the permeability at low flux densities was decreased and the hysteresis loss enormously increased, the latter 15 times. In other words, the reversible transformation produces a material with low hysteresis loss and low magnetic saturation, while the irreversible transformation produces a material with 6 times the saturation value, but with 15 times the hysteresis loss. Thermal and magnetic hysteresis thus go together.

It is also interesting to note that there apparently is no change in the microstructure of the 30 per cent alloy accompanying the marked magnetic and electrical transformation. Fig. 19 shows the microstructure of the alloy cooled to room temperature, and Fig. 20 after cooled to -70 deg. cent. and reheated to room temperature. The latter corresponds to magnetic and electrical properties widely different from those of the former, and yet the microstructures at 100 diameters are identical as far as can be seen. It is therefore apparent that the magnetic and electrical transformations are atomic or ionic in their nature.

The Fixation of Atmospheric Nitrogen by the Silent Electric Discharge Process–I

This paper is the the first of a series on the same type.

BY C. FRANCIS HARDING
Head, School of Electrical Engineering, Purdue University
AND
K. B. McEACHRON
Research Assistant, Engineering Experiment Station, Purdue University

THE very great increase in the demand for nitrates during the war for the manufacture of explosives and fertilizers, together with the shortage of imported Chile saltpeter, which was the principal source of nitrates before the war, has been emphasized sufficiently in previous papers. This condition of increased demand and curtailed supply led not only to the establishment of many manufacturing plants for the production of nitrates by well-known methods, but also to laboratory research and commercial development in connection with promising new processes.

Such a process, for obtaining nitric acid from the air by means of the silent electric or corona discharge at high voltage, has been investigated throughout a period of several years at Purdue University under the auspices of the Engineering Experiment Station of that institution. Improvements in the yield, resulting from a given input of electrical energy, are being made quite frequently as the investigation progresses and many of the peculiarities of both electrical and chemical reactions of the oxides of nitrogen, combined with ozone, are being disclosed as phenomena incidental to the process under consideration. It has, nevertheless, been considered advisable to present, as a progress report, the results obtained thus far in order that, in the spirit of co-operative research, discussions and suggestions of value will result which in turn will hasten the development of the process. With this object in view, the results of the investigation being carried on at Purdue University are presented in this paper.

It is well to point out at first the distinction between the process herein described and the arc method of nitrogen fixation. In the former, air is passed through an electro-static field of such intensity that marked corona and some static sparks are produced, but no power arc is established and the temperature is increased but slightly above that of the incoming air. While the arc process of nitrogen fixation is dependent principally upon the very high temperature of the power arc, the silent discharge reaction is the result of electrical ionization of the air at a relatively low temperature.

The fact that electro-static brush discharges and sparks will produce, in a confined volume of air, various oxides of nitrogen and ozone, has been known for many years. Oxidation of these lower oxides of nitrogen by an excess of ozone results in nitrogen pentoxide, N_2O_5. This gas, when absorbed in water, produces nitric acid from which the desired nitrates may readily be formed.

To be presented at the Boston meeting of the A. I. E. E., April 9, 1920.

Earlier Investigations

The investigation, to which this paper forms an introduction, was the result of the translation from the German, by Messrs. G. N. Unger, G. W. Payne and F. S. Weimer, of an article entitled, "The Formation of Nitric Oxides by the Silent Electric Discharge in a Siemen's Tube." The latter was submitted by Hugo Spiel for a doctor's degree at The Technical High School, Vienna, in 1909. Spiel gives credit for the first publication of the effect of this silent electric discharge upon air as follows:

> The first observations of the silent electric discharge in literature appeared about 1870, following the work of Andrew, Hauzau, Jean, Thenard and Boillit, with ozone and nitric acid. It concerned the decomposition of carbonic acid and turned the general interest to the chemical effect of the electric discharge in gases. In 1873 the French physicist, Moncel, published a work entitled, "Concerning the Condensed Discharge of the Induction Coil," in which he claimed to have discovered the above phenomena in 1853.

Following a review of the previous work done by others upon the problem, Spiel described a series of laboratory research investigations performed by him upon fixed volumes of air and various artificial nitrogen-oxygen mixtures. Spiel's apparatus consisted of a small glass or quartz Siemen's tube, using acidified water electrodes upon either side of an annular air space of only 3 mm. thickness. The electro-static discharge, within this space, was produced by an induction coil and condenser having a sparking distance of 40 cm., and a frequency of approximately 40 cycles per second.

As a result of the exposure of a confined volume of air to the electro-static discharge, at different pressures and voltages, Spiel noted during a single test; first, a decrease in pressure and later, at the minimum pressure, a reversal of the reaction. This reversal was indicated by the presence of brown fumes of NO_2. If the electric discharge was continued beyond this point, the pressure increased to the initial, or to a greater pressure, when equilibrium was established.

The conclusions reached by Spiel have been summarized in the appendix of this paper, because of the bearing they have upon this investigation and the inaccessibility of the original article.

Early Investigations at Purdue University

In planning a further investigation of this process,[1] it was decided that although the work must necessarily be performed with laboratory apparatus upon a comparatively small scale, when contrasted with commercial arc plants, the equipment should be designed and constructed in such a way as to provide for a continuous flow of air through the electric field. There is no reason apparent, therefore, to prevent the construction and continuous operation of a commercial plant based upon the same principle.

To produce the so-called "silent electric discharge" in a column of air, it is, of course, necessary to apply an electric potential between conducting plates or concentric pipes, Fig. 1, sufficient in magnitude to exceed the dielectric strength of air under the particular pressure at which such air is being forced through the apparatus, *i. e.*, the potential gradient must be such that the molecules of the air are torn apart into ions and neutral atoms which may reunite in new combinations. Such ionized air is a comparatively good conductor of electricity and unless special precautions are taken in the design of the tube, a power arc will result at one point and the potential will be lowered at other points in the field, thus eliminating the reaction.

Original Apparatus. The apparatus used in this first investigation is illustrated in Fig. 2. Following

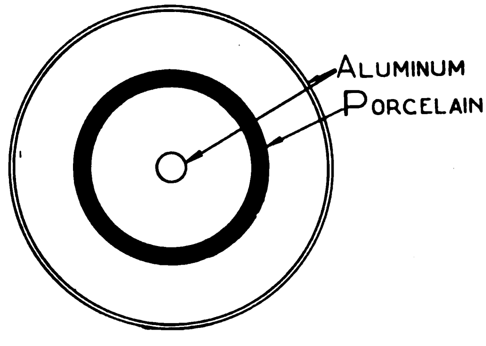

Fig. 1—Elevation of Corona Chamber

the passage of the air from the compressor on the left through air chamber, meter and drying apparatus in sequence, it passes into the discharge tube. This consists of a vertical aluminum tube 37.8 in. (96 cm.) in length and 2.91 in. (7.4 cm.) internal diameter, inside of which was mounted concentrically a glass tube of slightly greater length, 2.5 in. (6.35 cm.) diameter and 0.125 in. (0.318 cm.) thickness. This glass tube provides the barrier of higher dielectric strength than air to prevent the arc from forming. The potential is applied between a coaxial aluminum rod of 0.625 in. (1.59 cm.) diameter and the outer aluminum tube. The air passes upward between the glass and aluminum tube, and thence the gases pass downward between the central rod and the glass tube, emerging from the bottom into the mixing chamber. Receptacles are provided at the right with glass beads and distilled water or a solution of $N/10$ potassium hydroxide (KOH) for the fine subdivision and absorption of the gases. Traps are placed upon either side of the drying bottles to prevent the sulphuric acid, (H_2SO_4) which is used as the drying agent, from being carried into the meter or discharge tube. A similar trap is located between the mixing chamber and absorption apparatus to prevent the absorption water from being forced back into the mixing chamber.

1. Thesis entitled "The Fixation of Atmospheric Nitrogen by the Silent Electric Discharge at High Voltage," 1917 by G.W. Payne, G. N. Unger and F. S. Weimer.

Manometers and thermometers are installed, as indicated in the figure, for the purpose of determining pressures and temperatures of entering air and effluent gases, respectively.

Power Measurement. A potential in the neighborhood of 30 kilovolts, alternating at a frequency of 60 cycles, was furnished by a 200-kilovolt, 50-kv-a., air-cooled transformer. The tertiary coil of this transformer, whose potential was calibrated against the A. I. E. E. standard sphere gap in the secondary circuit, provided a convenient means of reading voltage. The potential terminals of the wattmeter were also connected to the tertiary coil. An ammeter and the current coil of a wattmeter were connected, as indicated in the figure, between the neutral point of the transformer winding and ground. Only one side of the transformer was used to supply the potential to the

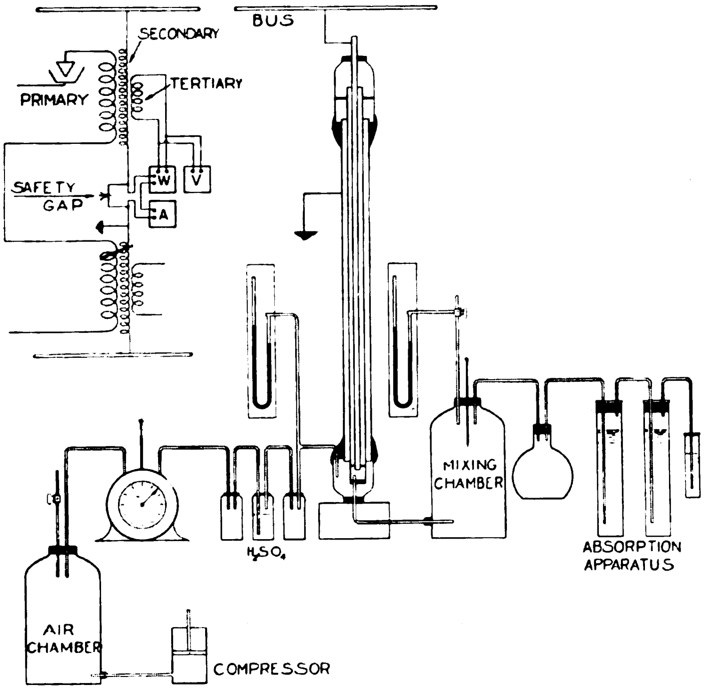

Fig. 2—Original Apparatus

discharge tube. Protective film cut-outs, connected around the meters, prevented accident in case the ground wires of the meters or tube should become disconnected. A Rowland dynamometer, calibrated over a wide range of power factor as a wattmeter, was used in these early tests for measuring the power input to the discharge tube. The difference between the readings of this dynamometer, with and without the tube connection, provided a measure of the net power supplied to the tube, quite apart from any transformer or corona losses on connecting bus bars. This method of power measurement is the same as that used in determining corona loss on transmission lines previously reported to the Institute.[2]

2. "Corona Losses between Wires at High Voltages," C. Francis Harding, Transactions A. I. E. E. Vol. XXXI (1912), page 1035.

With the methods of gas absorption and power measurement outlined, it was a comparatively simple matter to titrate the nitric acid formed or determine the amount of alkali neutralized thereby per kw-hr. of energy expended.

Conclusions of Original Investigation. The results of three (3) tests by Messrs. Unger, Payne, and Weimer are listed in Table I.

TABLE I.

NITRIC ACID YIELDS.

Test	Grams HNO_3 per kw-hour.
No. 1	4.17
2	2.55
3	5.55

A study of Table I indicates that thus far the yield by the silent discharge method is very much smaller than those of the arc processes. Some of the conclusions derived from the investigation as indicated seemed however, to warrant further research along similar lines.

1. The reaction is not necessarily a thermal one, but nitrogen pentoxide (N_2O_5) is formed at low temperatures by the action of the corona at high voltages.
2. Although this reaction is accompanied by much free ozone (O_3), the lower oxides of nitrogen, so objectionable in the arc process, are apparently not present to any great extent, except in case of reversal of the reaction.
3. Since the effluent gases consist principally of a mixture of nitrogen pentoxide (N_2O_5), ozone (O_3) and air, the absorption is more readily accomplished than with the arc process.
4. The gases emerge at comparatively low temperatures. Little energy is therefore carried away in the form of heat and no apparatus is needed to make efficient use of this heat energy.
5. The process is a continuous one and, as such, is more adaptable to commercialization than previous investigations of the silent discharge process which have been limited to a single confined volume of air.

Improved Apparatus

Encouraged by the possibilities of this process, in spite of the relatively low yields available thus far, the work was taken over upon a larger scale by the Engineering Experiment Station with the assistance of Messrs. H. W. Asire, S. S. Green and H. C. Thuerk.[3]

Apparatus operating upon the same principle, but much larger and more commercial in design, was constructed as indicated in Fig. 3.

3. Thesis entitled "The Fixation of Atmospheric Nitrogen by the Silent Electric Discharge Method," 1918 by H. C. Thuerk and S. S. Green.

The corona discharge takes place inside an aluminum tube five feet (1.52 m.) long and six inches (15.2 cm.) in diameter, mounted in a vertical position, the lower end being about 18 inches (45.7 cm.) from the floor. A 5/8-inch (1.59-cm.) aluminum rod is placed on the axis of the tube and extends 18 inches (45.7 cm.) above the end of the tube. The lower end of the rod is screwed into the end of a ½-inch (1.27-cm.) bakelite tube 15 inches (38.1 cm.) in length. A perforated

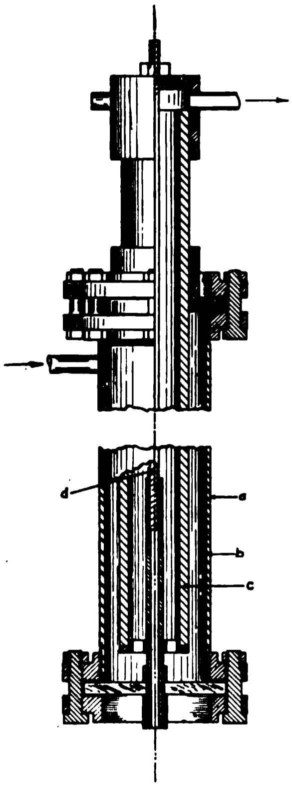

Fig. 3—Discharge Tube

a.—Wrought iron casing. c.—Porcelain dielectric.
b.—Aluminum lining. d.—Aluminum electrode.

bakelite disk, about four inches (10.2 cm.) in diameter, is arranged so that it may be screwed onto the outside of the bakelite tube. This disk furnishes the support for a glazed porcelain tube of three inches (7.62 cm.) inside diameter and ½ inch (1.27 cm.) thickness, the upper end of which projects beyond the end of the aluminum tube, but not as high as the aluminum rod. The top of the tube is closed with a bakelite cap placed over the end of the porcelain tube. A collar, also of bakelite, is inserted between the aluminum and the porcelain tubes. The joints between the porcelain and the bakelite are sealed with a rosin, beeswax and sealing wax compound, which is not appreciably affected by the gases. The bottom of the tube is sealed with a piece of thick plate glass, through the middle of which the bakelite tube is passed. By the use of a mirror, placed on the floor at the proper angle, a view of the inside of the tube is afforded.

Surrounding the aluminum tube is a length of wrought iron pipe, having flanges screwed on either end in such a way that the bakelite collar at the top and the plate glass at the bottom may be clamped securely.

In order that the temperature of the tube may be raised at will, a heating element, consisting of several hundred feet of iron wire, is provided. The heating element, wrought iron pipe and flanges are covered with a magnesia covering which decreases the radiation.

Air enters the tube near the top, and passes downward between the aluminum and porcelain tubes, through the holes in the bakelite disk and up through the inside of the porcelain tube, exhausting through a bakelite tube screwed into the cap over the end of the porcelain. The path of the air is shown in Fig. 4.

A mercury manometer, connected to the inlet pipe, indicates the relative pressure in the discharge tube. The temperatures of the incoming and outgoing gases are measured by alcohol thermometers whose bulbs are in actual contact with the gases. Mercury thermometers were not used on account of the breaking up of

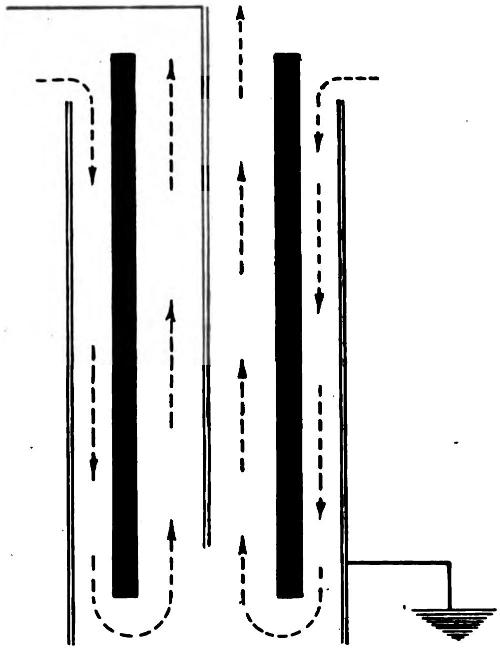

Fig. 4—Path of Air in Discharge Tube

the mercury column due to the static charges formed. The mercury is also a conductor which is, of course, a serious disadvantage, and makes their use unsatisfactory.

The aluminum rod is connected to the high-tension transformer, while the outer iron casing is grounded. With the proper voltage impressed on the discharge tube, the space both inside and outside of the porcelain tube may be filled with corona discharge.

Absorption Apparatus. The absorption apparatus consists of an absorbing chamber, separator and precipitator. This apparatus will be more easily understood by reference to Fig. 5.

The gases, leaving the discharge tube, bubble through a solution of sodium hydroxide (NaOH) of known strength, contained in the absorption chamber. The

bubbles of gas are made to come into contact with quite a large wetted surface as the chamber is partially filled with very short lengths of small glass tubing. The use of the tubing makes possible relatively high air velocities with but little back pressure. The absorbing liquid is titrated both before and after the run, in order to ascertain the amount of HNO_3 absorbed.

At certain air velocities, a fog is formed over the absorbing liquid and, in order to recover the acid carried with it, a separator, Fig. 5, working on the principle of the steam separator, is connected in series with the absorption chamber. In this separator the gas is forced to turn through an angle of 180 deg., while moving at a high velocity with the result that the heavier particles are thrown down, and collected in the bottom of the chamber.

From the separator, the gases pass to the precipitator, Fig. 5, in order that the finer particles of fog may be collected. This device is patterned after that of Cotrell. A glass tube, about 1½ inches (3.81 cm.) in diameter and 23 inches (58.4 cm.) in length, is coated with tinfoil up to within about six inches (15.2 cm.) of either end. The air passes in and out through the two side outlets blown in the glass near either end. A small (1/16-inch (1.59-mm.) diameter) aluminum wire, threaded throughout its entire length, is sealed into two small glass tubes about four inches (10.2 cm.) in length, which in turn are sealed into either end of the precipitator tube. Thus, quite a long creepage distance is secured, which is necessary when the surfaces become wet with nitric acid. This tube is operated with an induction coil giving a one-half inch (1.27 cm.) spark between needle points.

With the induction coil connected to the precipitator in such a way that the larger lobe of the wave is impressed on the threaded wire, the tube seems to work well. The smaller lobe is more or less excluded by point plate action.

Air Control. A small piston air pump is connected to a system of valves, in such a way that the discharge tube may be operated under pressures above or below the atmosphere, by a simple manipulation of the valves. The valves are provided with a pointer and dial, so that settings may be duplicated at any time. The fluctuations due to the pump are smoothed out by the use of an air tank, whether the system is working under pressure or vacuum. The air pump is driven by a d-c. motor, arranged with armature control of the speed. A voltmeter is connected across the armature circuit to act as an indicator of the motor speed.

Air leaving the pump bubbles through sulphuric acid, contained in two chambers in series, and then passes on through a tube containing soda lime. By

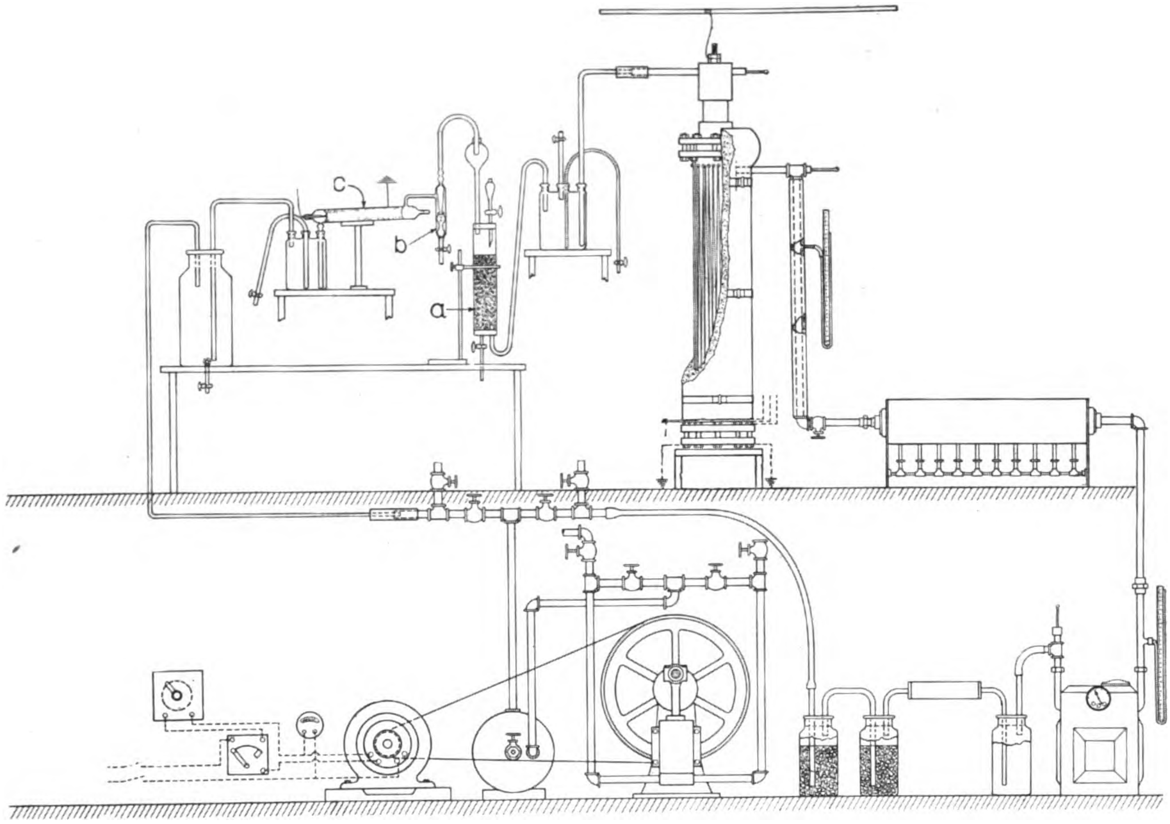

Fig. 5—Improved Apparatus
a.—Absorption chamber. b.—Separator.
c—Precipitator.

this process the air is rendered practically free from moisture and carbon dioxide CO_2.

A special gas meter, having a capacity of 100 cu. ft.,

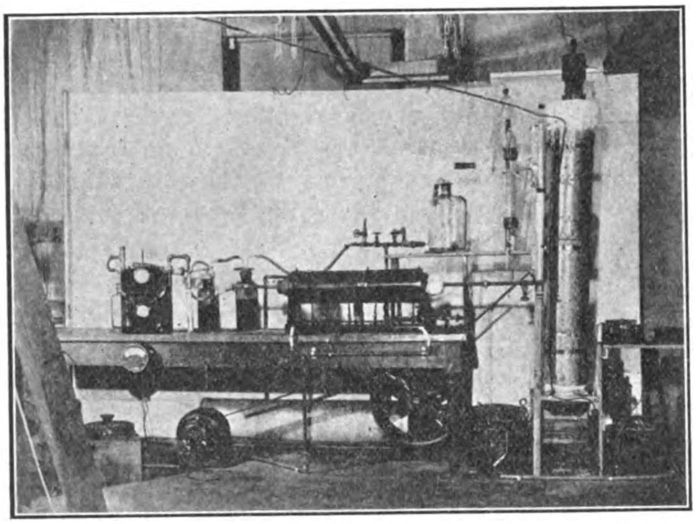

Fig. 6—Experimental Apparatus

(28.32 liters) is connected to a settling chamber through which the air passes after leaving the soda lime chamber. By use of the large dial with which the meter is pro-

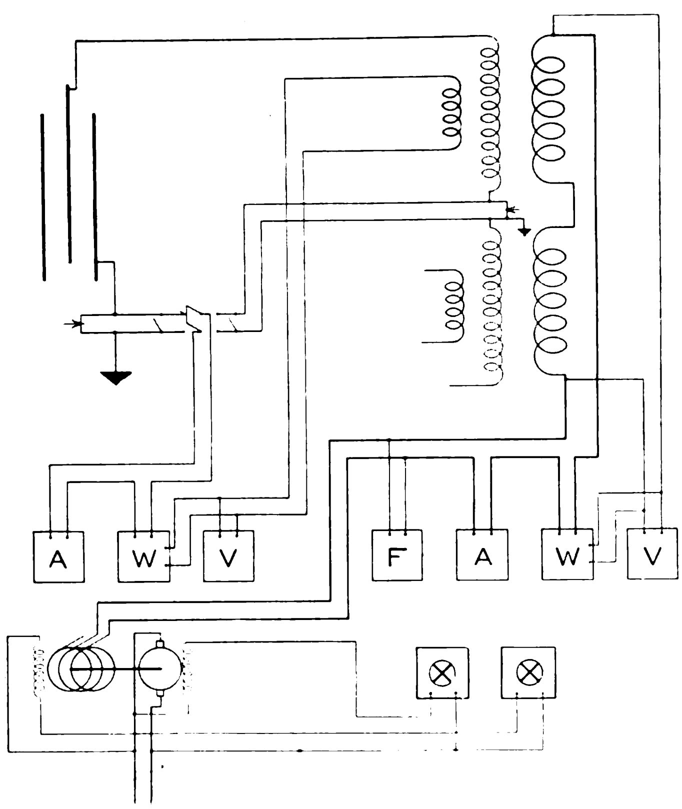

Fig. 7—Diagram of Connections

vided, readings are possible to one one-hundredth (0.01) of a cu. ft. (0.283 liter). The temperature and pressure of the air at the air meter are measured because the air meter is not capable of withstanding all of the pressures used in the discharge tube.

Upon leaving the air meter, the air passes through an air heater, where its temperature may be raised as much as required. This heater consists of a long tube, heated by ten gas burners, properly insulated to prevent excessive radiation. In some of the earlier work, the heater was used in conjunction with the heating element on the discharge tube to hold a constant temperature. It was found however, after several trials, that small temperature changes did not seem to affect the yields materially, and as a result all of the tests recorded in this paper were made at room temperature.

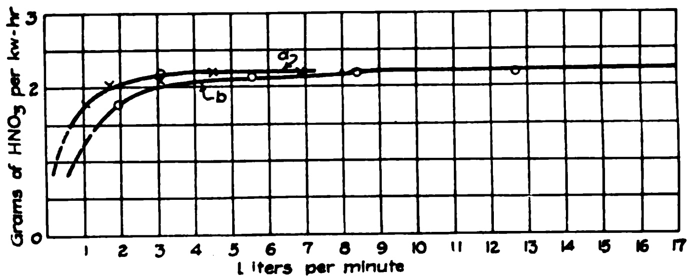

Fig. 8—460 mm.

a.—n. t. p. b.—actual.

This was of course held as nearly constant as possible. It is planned to make a set of runs in which the temperature will be made the independent variable. Upon leaving the gas heater the air passes through a valve, used for regulating the tube pressure, and then enters the discharge tube.

Power Measurement. The high tension winding of the transformer was grounded at its neutral point. The other terminals were connected to high-tension

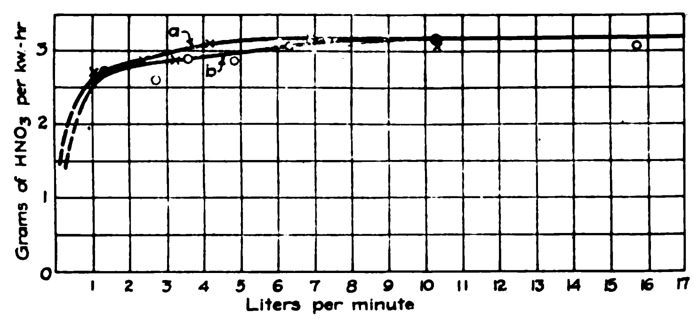

Fig. 9—560 mm.

a.—n. t. p. b.—actual.

buses. Each half of the secondary may be operated up to 100 kv. The excitation for the transformer is furnished by an alternator which gives practically a sine wave.

A test table has been arranged, equipped with various meters and rheostats. On this table, switching arrangements, Fig. 7, are provided so that the current in either circuit, *i. e.* from transformer to ground or, from discharge tube to ground, may be read on the same milliammeter. These currents differ because of the capacity of the transformer coils to ground, and also because of the actual electrostatic leakage occurring in the transformer.

A special low-reading wattmeter, whose potential coil is connected to the tertiary coil on the transformer, has its current coil in series with the milliammeter in order that readings of watts in tube circuit and transformer circuit may be taken independently. There is some considerable variation in the readings of the wattmeter in the two circuits with varying pressure in the discharge tube. This variation in wattmeter readings appears to be a function of the static sparks in the tube, and is greater than can be accounted for by capacity effects alone. This matter will be the subject of future investigation.

Meters were connected in the primary circuit of the transformer for measuring the input power. The net power measured from the primary side has checked

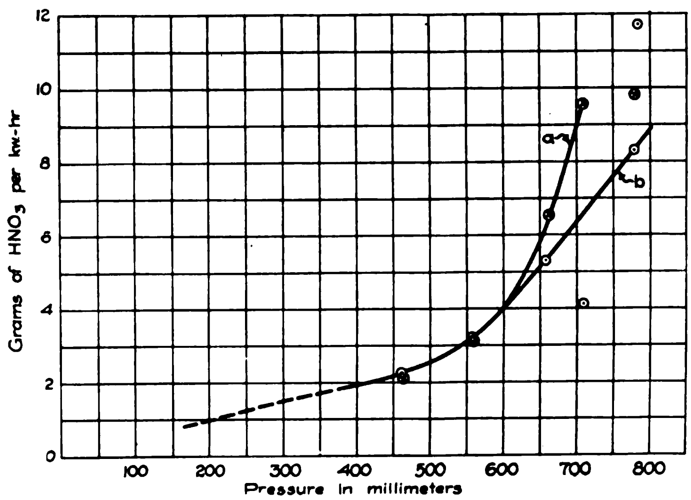

FIG. 13—PRESSURE YIELD CURVES
Constant Air Velocity (n. t. p.).

that observed on the secondary side within 10 per cent in practically every run made.

Results of Tests. A series of runs at pressures of 460, 560, 660, 710, and 780 mm. has been made. The power in the transformer circuit to ground was held

constant during all of these runs. The frequency was 60 cycles. Each run was 45 minutes in length. For each pressure a series of runs was made with air velocity as the variable. Figs. 8, 9, 10, 11, and 12 show the yield of HNO_3 per kilowatt-hour of energy

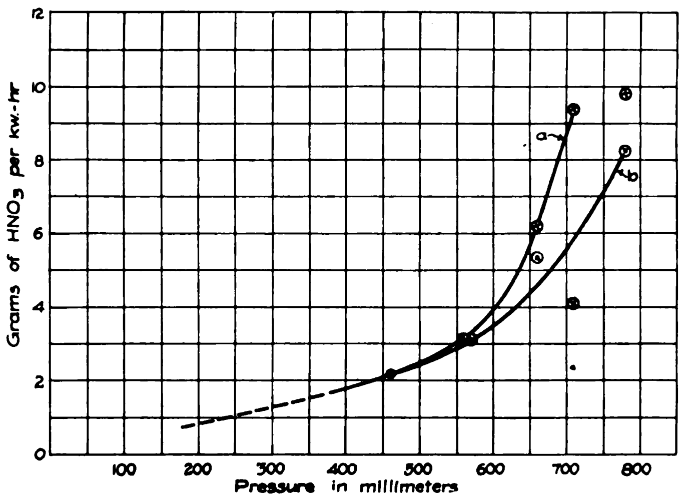

FIG. 14—PRESSURE YIELD CURVES
Constant Air Velocity (actual).

expended in the tube. The curves marked "Actual Velocity" refer to the actual velocity of a particle in passing through the discharge tube.

Figs. 13 and 14 show the relation between pressure and yield with constant air velocity. From these

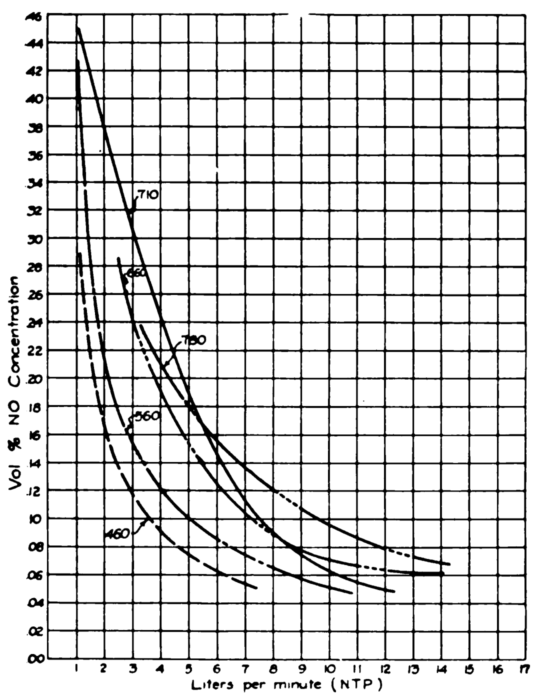

FIG. 15

curves it may be seen that the yield at the lower velocities is limited, but that at the higher velocities the limit has not yet been approached.

From the equations for the formation of nitric acid, it may be seen that the concentration of N_2O_5 will be half that of *N O* for any given value of nitric acid.

$$2NO + O_3 = N_2O_5$$
$$N_2O_5 + H_2O = 2HNO_3$$

The N O first formed is oxidized to N_2O_5 by the excess of ozone present so the N_2O_5 may be contrasted with 2 N O for the same yield of nitric acid.

The relation between per cent concentration of fixed nitrogen, calculated as N O, velocity and pressure is given in Figs. 15 and 16. These curves show that high concentration is to be secured at low velocity, but as seen in Figs. 13 and 14 at the expense of energy input. The concentration curves are therefore somewhat misleading from a commercial standpoint.

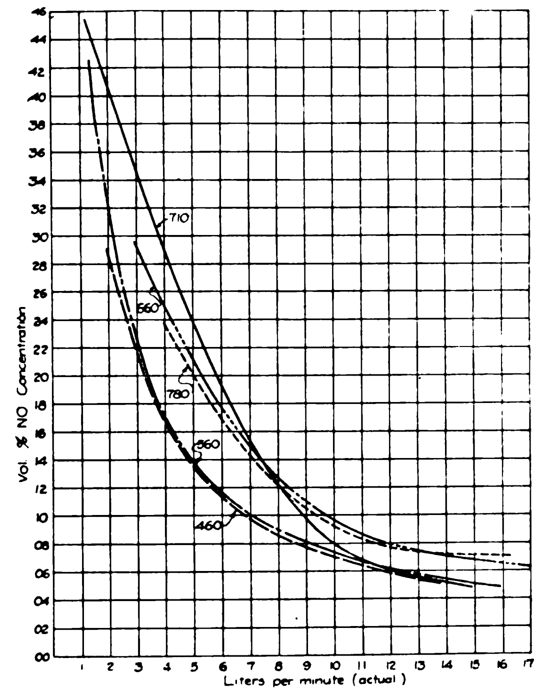

FIG. 16

It seems probable that all of the velocity-yield runs for the different pressures should follow the same general form. At low pressures the amount of gas to be dissolved was low and the efficiency of absorption higher. At the higher pressures, with more gas to take up, it is likely that the absorption was incomplete, especially at high velocities. Data taken recently have shown this to be the true condition.

From Fig. 12 the highest yield is seen to be 9.8 grams HNO_3 per kilowatt-hour. This is more than double the average yield obtained with the original apparatus. (Table I). From the results of unfinished work it is apparent that this yield can be materially increased by using the improved methods of absorption which are now being worked out. The N O concentration for this velocity and pressure is 0.204 per cent.

One of the greatest complications of this problem is the number of variables to be controlled. The

large number of variables explains the apparent contradictions so often found in the literature of the silent discharge. It has taken considerable time and patience to acquire the ability to secure sufficiently constant conditions so that runs may be made which will check satisfactorily. Very great care has been necessary in making the various runs and taking the data, to eliminate as far as possible personal errors.

Considerable difficulty encountered in the early work was that of keeping the joints tight. The situation was complicated by the fact that rubber joints in contact with ozone are destroyed in a very few minutes.

A beeswax, sealing wax, and rosin compound, which has been referred to before, was developed for use in making joints and has given excellent results. The proportions by weight are: Sealing wax 3; beeswax 2; rosin 5. The joints are made in about the same manner as the plumber wipes a lead joint.

Incidental Phenomena.—Fog. At certain air pressures and velocities a white fog is formed over the surface of the absorption liquid. In the low pressure tests slight fog is formed, while at the higher velocities no fog appears. In many cases the fog is an initial condition disappearing after the first ten or fifteen minutes of operation. As the pressure is increased the fog becomes stronger and in general remains longer, until at 780 mm. pressure the fog, at a velocity of six liters per minute, is so dense that it is not possible to see through three inches of it. The fog is found to contain some nitric acid, its concentration being subject to considerable variation. The fog formation is being investigated further.

Meter and Pressure Variation.—At certain air velocities the readings of all the meters connected in the transformer and tube circuits and, to a lesser degree those in the primary circuit show a cyclic variation. At low pressures the effect is very slight, but with increasing pressure it becomes more pronounced. The greatest variation at each pressure occurs at an actual velocity of six liters per minute. At velocities above and below this, the indications rapidly become steady. With but one exception, these variations do not extend over a period of more than 40 minutes. In most cases they do not occur after the first 20 minutes of operation.

When the variations are most pronounced, the manometer connected to the discharge tube shows a disturbance corresponding to that of the electric meters. The frequency seems to be about two per second, although it is not by any means constant.

From the velocity yield curves given in Figs. 8, 9, 10, 11, and 12, it is to be noticed that the curves begin to flatten out at about the critical velocity of six liters per minute.

In the discharge tube, nitrogen pentoxide (N_2O_5) is being formed, while at the same time, if subjected to discharge for too long a period, it is again broken down. These two actions are therefore opposing one another and both are a function of time. This action may have some bearing on the observed variations.

Another effect which should be mentioned has been termed "Initial effect." During practically every run made, in order to hold the wattmeter deflection constant, the primary voltage had to be reduced as the run progressed. This average potential decrease during runs amounted to about 3 per cent. The tertiary coil voltage did not show as high a percentage variation and in some cases no change was noted. Most of the observed changes took place in the first fifteen minutes of operation.

Analysis of Losses. The energy consumption in the discharge tube may be divided into four parts.

1. Warming up the Material of the Tube. Using the weight of the iron and aluminum parts of the tube, and the specific heats of the metals, an expenditure of 14.14 watthours will be required per degree cent. temperature rise.

2. Loss in the Porcelain Dielectric. In order that some idea of the magnitude of the dielectric losses in the porcelain might be obtained, a series of heat runs on a regular discharge porcelain tube was made. The outside of the tube up to within about a foot (30.5 cm.) of either end was covered with tinfoil, the corona discharge from the tinfoil edges being prevented by pressboard collars sealed over them. A snug fitting metal tube three inches (7.6 cm.) in diameter was slipped inside the porcelain, its length being such that the dielectric field was not distorted by its ends. The tinfoil was grounded, the inner tube being connected to the high tension supply. Alcohol thermometers placed on the tube indicated the temperature of the tube. From curves taken during this test the power loss in the porcelain dielectric will be of the order of 10 watts, its exact value depending upon the value of the current flowing, in any particular case. From the observed temperatures of the discharge tube and effluent gases the temperature rise of the porcelain is greater than that which would be caused by its own dielectric loss. On account of this the energy calculated as being used in warming up the porcelain will exceed the value obtained by test.

3. Heat Carried away by Discharge Gases. The amount of heat carried away by the air is very small, being of the order of 0.20 watthour per 1000 liters of air per degree cent.

4. Energy used in the Chemical Reactions. Using the figures given by Berthelot[4] the amount of energy required for the formation of enough N_2O_5 to produce one gram of nitric acid is 95.4 calories, or 0.11 watthour. For the ozone 667 calories or 0.78 watthours are required.

Assuming that the wrought iron tube and the aluminum tube are at the same temperature, and that the

4. Smithsonian Physical Tables, 6th Edition.

porcelain tube is at the temperature of the discharge gases the following energy relations are secured, based upon their respective weights, specific heats and assumed temperatures.

Metal parts Average rise 5.6 deg. cent. loss	= 79.2 watthours
Porcelain tube Average rise 9.35 deg. cent. loss	= 27.1 watthours
Effluent gases 9.35 deg. rise—478 liters loss	= 0.9 watthour
Chemical reactions 2.13 grams HNO_3 (per hour)	= 0.24 watthour
0.96 grams ozone	= 0.78 watthour
	108.2

The power read on the wattmeter when connected in the tube circuit was 134 watts, leaving a difference of 25.8 watthours to be accounted for. Some of this may be due to temperatures existing inside the discharge tube higher than those used in the calculations. This error is not likely to be very large, however.

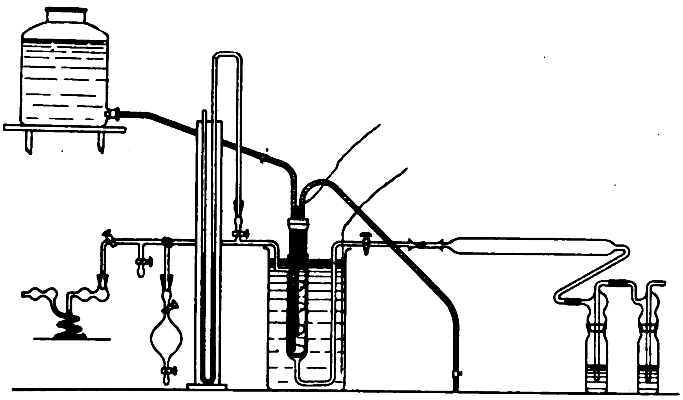

Fig. 17—Spiel's Apparatus

Conclusions. This work is but well begun, and no prediction can be made with any degree of certainty, yet the results obtained thus far are quite promising. Improved absorption apparatus has already indicated that increased yields may be expected. The process is very simple, and the first cost and maintenance of a plant would not be high. The difficulties of operation associated with the use of high temperatures are obviated.

Referring to Anderegg's calculations,[5] based upon his theory of the reaction, the ideal yield from the silent discharge process, if all the electrical energy were available for the reaction, would be 250 grams of nitric acid per kilowatt-hour. The theoretical possibilities from the thermal reaction, according to thermodynamical calculations, represent a yield of only 134 grams of acid per kilowatt-hour at a temperature of 4200 deg. cent. If the former process can be developed to the present efficiency of the arc process, the yield will be greater and the first cost and operating expenses will probably be much less because of the simpler apparatus involved.

5. "The Calculation of the Efficiency of the Silent Discharge Process for Nitrogen Fixation," F. O. Anderegg, Science, 50, 49 (1919) and Chemical Abstracts *13*, 3090 (1919).

In general, those reactions approximating most closely natural phenomena are found ultimately to be most satisfactory and economical. Nature provides dilute nitric acid for the fertilization of the soil by the ionization of the air as a result of electric discharges in the atmosphere. The gases thus produced are absorbed by the moisture of the clouds or rain and are distributed over the land. Such a process is identical in principle with that under discussion in this paper.

This work has been accomplished only by the generous cooperation of many interested investigators. Dr. F. O. Anderegg in particular, Assistant Professor of Chemistry at Purdue University, has followed the work in detail and has made many suggestions of value. The hearty appreciation of the authors is extended to him, to other collaborators mentioned in the paper, to Professor H. C. Peffer, Head of the School of Chemical Engineering, and Mr. Emerson Pugh, instructor in the School of Electrical Engineering. The departments of Chemistry and Physics have also rendered services which are hereby recognized with appreciation.

The Engineering Experiment Station at Purdue University will continue the investigation of the "Fixation of Atmospheric Nitrogen by the Silent Discharge Process."

APPENDIX

In Table I will be found a summary of the results of Spiel's experiments upon fixed volumes of air. The change of primary current of the induction coil indicated in the second column of the table, no doubt varied the voltage of the secondary and therefore the energy input to the Siemen's tube over a considerable range, but no record of such energy or the yields of nitric acid were reported.

TABLE I.
SUMMARY OF SPIEL'S RESULTS

No. of experiment.	Prim. current.	Pressure mm.	Temperature deg. cent.	Time reversal minutes	Time equilibrium minutes	N O concentration vol. per cent
1	1.9	715 –744	12 –15.3	120	175	0.7
2	1.9	716 –748.5	14 –14.2	110	..	4.4
3	1.9	481.5–503.5	14.3	39	51	0.6
4	1.9	481.5–502	15	43	..	5.6
5	1.9	345.5–353.5	16 –16.1	14	85	0.5
6	1.9	344 –352	15.5–15.7	11	..	6.6
7	3.0	729.5–746	17 –17.1	30	50	0.4
8	3.0	721.5–746.5	16.1–16.2	31	..	4.2
9	5.0	731 –760	14 –14.2	11	80	0.1
10	5.0	731 –750	14	11.5	..	3.6

The analyses were made after the equilibrium was reached for the experiments of odd number. In the even numbered experiments, the analyses were made as near the reversal point as possible.

Conclusions

The conclusions derived by Spiel as the result of his work on air are quoted as follows:

1. "With the discharge in enclosed volumes of air the final equilibrium concentration gives nitric oxide below one volume per cent for these conditions."

2. "Decrease of the original pressure essentially alters the equilibrium concentration."

3. "Increase in the primary current decreases the equilibrium concentration."

4. "The pressure decrease, which the gas undergoes, as is to be seen from curve, Fig. 17, varies between 8 and 34 mm. This pressure decrease depends not only upon the formation of ozone, but also upon the formation of oxides of nitrogen for, as can be seen from the red color of the gas at the time of reversal, and as has been proven by the determinations of concentration, much more oxidized nitrogen is present before and at the time of reversal, than at equilibrium."

This abrupt and strong reversal is a very peculiar phenomenon. It has been checked by Anderegg in the Chemical laboratory of Purdue University. The reversal has been shown by Spiel to be affected by changes of temperature. An investigation is being

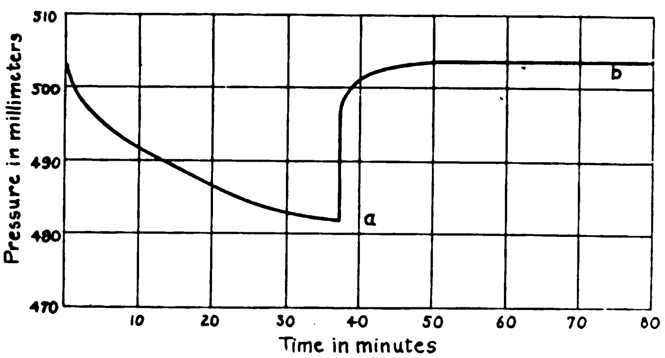

FIG. 18

a.—5.6 vol. per cent N O.
b.—0.6 vol. per cent N O.

undertaken by R. E. Nelson to see what effect the maintenance of a very constant temperature will have on the reversal.

5. "The concentration at the time of reversal in experiments at atmospheric pressure is about six times the final concentration. For lower pressures this ratio is raised, the final concentration being lowered; the reversal concentration increases rapidly. With 500 mm. pressure at the time of reversal about 10 times, with 350 mm. about 12 times as much NO is present as in the final equilibrium."

6. "With increased current, the reversal as well as the final concentration decreases considerably."

7. "The time after which reversal occurs varies between 12 and 110 minutes; the latter time, which was obtained with air at atmospheric pressure and 1.9 amperes, agrees with the results of Hantefeuille-Chappius."[6]

6. *Comptes rendus* 92 (80), 1881; 92 (134), 1882.

The conclusions reached by Spiel resulting from experiments with initial mixtures of air and various proportions of oxygen and nitrogen are to the effect that the concentration is increased and the time required to produce a reversal of the reaction is lowered by higher oxygen concentrations. He further decides the "The Silent Electric Discharge is not concerned with a thermal effect."

SPECIFICATIONS FOR STARTING AND LIGHTING BATTERIES FOR MILITARY TRUCK SERVICE

Special importance attaches to the formulation of satisfactory specifications for batteries intended for starting and lighting service, because of the magnitude of the industry at the present time and the fact that many new manufacturers are entering the field. The government desires adequate specifications to insure getting good batteries and it is believed that the government specifications, carefully drawn, will react to benefit the public who purchase these batteries in enormous quantities every year.

A conference was held at the Bureau of Standards on February 25th to consider a draft of specifications which has been prepared by this Bureau at the request of the Motor Transport Corps. These specifications, while intended for the Motor Transport Corps particularly, will probably receive wider acceptance in view of the fact that there appear to be no adequate specifications for starting and lighting batteries at the present time.

The conference was called, at the request of the Motor Transport Corps, by the Society of Automotive Engineers who invited members of the Electrical Equipment Committee of that society, representatives of the manufacturers, members of the American Institute of Electrical Engineers' Committee on Storage Batteries, representatives of the Navy Department, the Bureau of Standards, and the Motor Transport Corps.

The matters discussed included the capacity and arrangement of the batteries; the method of rating them; specifications for the construction, quality of materials, and the electrolyte. Tests of the battery were outlined to include measurements of the capacity, the retention of charge, the purity of the electrolyte, life tests and vibration tests. While the general form of the specifications was agreed upon, together with a satisfactory system of ratings, some details as to dimensions and performance were left for further consideration of sub-committees, and, consequently, it will be some time before the specifications will be ready for publication.

APRIL INSTITUTE MEETING IN BOSTON

On Friday April 9, 1920, the American Institute of Electrical Engineers will hold its 359th meeting at the Copley Plaza Hotel, Copley Square, Boston, Mass. This meeting will be held jointly with the American Electrochemical Society and will be under the auspices of the Boston Section and the Committee on Electrochemistry and Electrometallurgy. Arrangements have been made for the registration of Institute members in the lobby of the hotel at 9 a. m.

The first Institute session, held jointly with the A. E. S., will open in the Swiss Room on Friday at 9:30 a. m. for the reading and discussion of the papers of the symposium *Electrically Produced Alloys*. A trip to the Lynn works of the General Electric Company is scheduled for 1:30 p. m. At 6:30 p. m. a subscription dinner will be served in the Swiss Room, followed by the second technical session at which papers will be presented in the symposium *Power for Electrochemical Purposes.*

On Thursday, April 8th, the A. E. S. will hold sessions at the Copley Plaza, morning and afternoon; and on Saturday, April 11th, in the morning at Harvard University. On Thursday evening at 8:30 p. m. the A. E. S. has planned a Get-together Smoker at the Copley Plaza. Institute members are cordially invited to attend all of these functions.

PROGRAM

Friday, 9:30

SWISS ROOM, COPLEY PLAZA HOTEL.

Technical Session on "Electrically Produced Alloys."

A. I. E. E. PAPERS:

Electric and Magnetic Properties of Nickel-Iron Alloys, by T. D. Yensen.

Nitrogen Fixations by the Silent Discharge Method, by C. F. Harding and K. B. McEachron

A. E. S. PAPERS:

Properties of Ferro Silicon, by F. A. Raven

Ferro Manganese, by E. S. Bardwell.

Manufacture of High-Speed Steel in the Electric Furnace, by R. C. McKenna.

Ferro Cerium, by Alcan Hirsch.

Ferro Zirconium, by Theodore Swann.

Ferro Phosphorus, by B. G. Klugh.

Nichrome and Other Special Alloys, by R. M. Major.

Electrical Properties of Titanium Alloys, by M. A. Hunter.

1:30 p. m.

Inspection Trip to Lynn Works of the General Electric Co.

6:30 p. m.

Informal Subscription Dinner at the Copley Plaza Hotel.

8:30 p. m.

Technical Session on "Power for Electrochemical Industries."

A. I. E. E. PAPERS:

Power for Electrochemical Plants, by John M. Harper.

Automatic Control of Arc Furnace Electrodes, by John A. Seede.

Reactors for Electric Furnace Circuits, by H. A. Winne.

Economies of the Power Situation, by C. A. Winder.

A. E. S. PAPERS:

Electric Furnace Power from the Standpoint of the Central Station, by E. A. Wilcox.

The Electric Furnace and the Central Station, by H. L. Hess.

Location of a New England Electrochemical Plant, by C. T. Maynard.

Water Powers on the Pacific Coast, by F. F. Fowler.

Power Development in Scandinavia, by J. W. Beckman.

Power Problems from the Standpoint of the Furnace Operator, by W. G. Berlin.

Inspection Trip

On Friday afternoon there will be an inspection trip through the works of the General Electric Company at Lynn, Mass. This trip will be in charge of the General Electric Company, which has very kindly offered to supply transportation from in front of the hotel to the Lynn works and return. Trolley cars will leave promptly at 1:30 p. m. A printed description of the trip may be obtained at the registration desk on Friday morning.

Dinner

A subscription dinner will be served in the Swiss Room of the Copley Plaza Hotel at 6:30 p. m. Tickets should be obtained at the registration desk as early as possible in order that the dinner Committee may make arrangements for the required accommodations.

FUTURE A. I. E. E. MEETINGS

New York, May 21, 1920. Annual business meeting of the Institute, at which the annual report of the Board of Directors will be presented, and the report of the Tellers Committee announcing the officers elected for the coming year will be read. The Edison Medal will be presented to William LeRoy Emmet.

Annual Convention, June 29-July 2. The annual convention of the Institute will be held at the Greenbrier, White Sulphur Springs, West Virginia, June 29-July 2. President Townley has appointed the following Convention Committee:

Messrs. John H. Finney, Chairman
Walter A. Hall
F. L. Hutchinson
Farley Osgood
Charles Robbins
A. M. Schoen
W. I. Slichter

This committee will make all necessary arrangements for the Convention, with the exception of the technical sessions for which the Meetings and Papers Committee will provide.

Pacific Coast Convention, Portland, Ore., July 21-23. The 1920 Pacific Coast Convention will be held at Portland, Ore., July 21-23. Details will be announced later.

FUTURE SECTION MEETINGS

Cleveland.—April 20, 1920. Subject: "The Sperry Gyroscope." Speaker: Mr. Robert B. Lea, Sperry Gyroscope Company.

May 18, 1920. Subject: "Some Present Day Problems in Electrical Research." Speaker: Prof. V. Karapetoff, Cornell University.

A. I. E. E. DIRECTORS MEETING

MARCH 12, 1920

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at the Duquesne Club, Pittsburgh, on Friday, March 12, 1920, at 11:00 a. m.

There were present: President Calvert Townley, New York; Managers Charles S. Ruffner, Wm. A. Del Mar, L. F. Morehouse, New York, Charles Robbins, Wilfred Sykes, F. D. Newbury, Pittsburgh, E. H. Martindale, Cleveland, Walter A. Hall, West Lynn, Mass.; Secretary F. L. Hutchinson, New York.

A report was presented of a meeting of the Board of Examiners held March 8, 1920; and upon the recommendation of the Board the following action was taken upon pending applications: 73 Students were ordered enrolled; 227 applicants were elected to the grade of Associate; 15 applicants were elected to the grade of Member; 1 applicant was elected to the grade of Fellow; 14 applicants were transferred to the grade of Member; 1 applicant was transferred to the grade of Fellow.

The Secretary announced the following committee appointments made by the President since the last Board meeting: Annual Convention Committee—John H. Finney (Chairman), Walter A. Hall, F. L. Hutchinson, Farley Osgood, Charles Robbins, A. M. Schoen, W. I. Slichter; U. S. National Committee of the International Electrotechnical Commission—James Burke appointed a second Vice-President of the Committee, P. G. Agnew, Walter C. Fish, A. H. Moore, additional members; Board of Examiners—Professor J. H. Morecroft, to succeed Murray C. Beebe, resigned.

Upon the recommendation of the Chairman of the Sections Committee, a request for authority to organize an Institute Section at Providence, R. I., was granted.

Mr. L. T. Robinson was appointed as an alternate for Mr. H. M. Hobart as a representative of the Institute on the American Engineering Standards Committee during Mr. Hobart's absence in Europe as a delegate of the U. S. National Committee of the I. E. C. to a meeting in Brussels, March 27.

The Secretary announced that arrangements have been made for a Carnegie Memorial Service in the Engineering Societies Building, New York, on Sunday, April 25, at 4:00 p. m., several societies cooperating with the United Engineering Society.

Upon the recommendation of the Finance Committee, monthly bills amounting to $20,377.19 were approved.

In addition to these routine actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the Journal under suitable headings.

A. I. E. E. ANNUAL ELECTION

At the meeting of the Board of Directors of the Institute held in Pittsburgh, March 12, the report of the Tellers Committee giving the result of its canvass of the nomination ballots received for the offices to be filled at the coming annual election, was presented.

This report included the names of all candidates eligible for election, the names of those who received less than 3 per cent of the total nomination vote having been eliminated, in accordance with the requirements of the Constitution.

The Board resolved itself into a committee of the whole and an informal discussion followed, at the close of which the committee arose and reported its recommendations to the Board. The Board then selected a complete ticket of "Directors' Nominees" for the respective offices, in accordance with the provisions of the Constitution. This ticket is as follows:

For President:	A. W. Berresford, Milwaukee, Wis.
For Vice-Presidents:	C. S. Ruffner, New York, N. Y.
	E. H. Martindale, Cleveland, O.
	Charles Robbins, Pittsburgh, Pa.
	C. E. Magnusson, Seattle, Wash.
	C. S. McDowell, U. S. Navy
	L. T. Robinson, Schenectady, N. Y.
For Managers:	E. B. Craft, New York, N. Y.
	Harold B. Smith, Worcester, Mass.
	James F. Lincoln, Cleveland, O.
For Treasurer:	George A. Hamilton, Elizabeth, N. J.

The election ballots will be mailed to the entire membership prior to April 1.

A complete report of the Tellers Committee follows:

March 5, 1920

To the Board of Directors,
American Institute of Electrical Engineers.

Gentlemen:

This Committee has counted and canvassed, in accordance with Article VI of the Constitution, the nomination ballots received for officers of the Institute for 1920-1921. The result is as follows:

Total number of envelopes said to contain ballots, received from the Secretary		1049
Rejected on account of bearing no identifying name on outer envelope	13	
Rejected on account of having reached Secretary's office after Feb. 28	128	
Rejected on account of ballot carrying signature of voter	1	142
Leaving as valid ballots		907

These valid ballots were counted and the result is shown below:

FOR PRESIDENT

A. W. Berresford	324
C. E. Skinner	111
A. M. Schoen	61
William McClellan	38
N. A. Carle	38
J. B. Fisken	30
Scattering and blank	305
Total	907

(The scattering vote was divided among 69 candidates, each of whom received less than 3 per cent of the total vote. Detailed distribution of these votes is shown on the original tally sheets filed in the Institute offices.)

FOR VICE-PRESIDENTS

C. S. Ruffner	711
E. H. Martindale	700
Charles Robbins	698
C. E. Magnusson	686
C. S. McDowell	142
L. T. Robinson	89
J. B. Whitehead	80
H. P. Liversidge	51
Robert Sibley	34
W. S. Lee	33
Philip Torchio	32
Scattering and blank	2186
Total	5442

(The scattering vote was divided among 272 candidates, each of whom received less than 3 per cent of the total vote. Detailed distribution of these votes is shown on the original tally sheets filed in the Institute offices).

FOR MANAGERS

E. B. Craft	679
Harold B. Smith	665
James F. Lincoln	649
Scattering and blank	728
Total	2721

(The scattering vote was divided among 86 candidates, each of whom received less than 3 per cent of the total vote. Detailed distribution of these votes is shown on the original tally sheets filed in the Institute offices).

FOR TREASURER

George A. Hamilton	687
Scattering and blank	220
Total	907

(The scattering vote was divided among 13 candidates, each of whom received less than 3 per cent of the total vote. Detailed distribution of these votes is shown on the original tally sheets filed in the Institute offices).

Respectfully submitted

EDW. J. K. MASON, *Chairman*
PHILANDER NORTON
CHAS. M. FULK
WILLIAM P. ABENDROTH
P. C. PAQUETTE
Committee of Tellers

A. I. E. E. MEETING IN PITTSBURGH

The 358th Meeting of the Institute was held at the William Penn Hotel, Pittsburgh, Pa., on March 12th, under the auspices jointly of the Pittsburgh Section and the Traction and Transportation Committee. The total attendance of members and guests was approximately 600.

The morning was devoted to an inspection trip through the works of the Westinghouse Electric & Mfg. Co. at East Pittsburgh, after which the visitors were entertained at luncheon by the company.

The afternoon technical session was called to order at 2:30 p. m. in the ballroom of the hotel. After opening remarks by President Townley congratulating the Institute on the progress made since its inception, on its largely increased membership, and the position it occupies in the field of electrical engineering, both nationally and internationally, J. G. Carroll, Chairman of the Pittsburgh Section presided. The papers of the afternoon session were then presented: "Short-Circuit Protection of D-C Substations" by J. J. Linebaugh, read by C. M. Davis; "Flashing of 60-Cycle Synchronous Converters and Some Suggested Remedies," by Marvin W. Smith; "Automatic Railway Substations," by Frank W. Peters; "Automatic Substations for Heavy City Service," by R. J. Wensley.

These papers were discussed by F. D. Newbury, S. Q. Hayes, C. H. Jones, D. C. Hershberger, C. A. Butcher, Donald Bowman, Frank W. Peters, J. F. Trittle and L. D. Bale. Closure by the authors, J. F. Trittle closing for J. J. Linebaugh.

A telegram was read from W. S. Murray, Chairman of the Traction and Transportation Committee regretting his absence.

The informal dinner which was served at the hotel at 6:15 p. m. was attended by over 300 of the members and guests. At the dinner, S. M. Kintner acted as chairman and brief addresses were made by E. H. Sniffin, Manager of the Power Department of the Westinghouse Elec. & Mfg. Co., A. W. Thompson, President of the Duquesne Light Co. and Pittsburgh Railways Co., and President Townley. J. G. Carroll, Chairman of the Pittsburgh Section, thanked the company for their attendance.

At the evening session two papers were presented on "The Two Designs for the Chicago, Milwaukee and St. Paul Locomotives," by A. F. Batchelder and S. T. Dodd, (read by Mr. Dodd) and N. W. Storer. These papers were discussed by S. Q. Hayes, R. L. Wilson, R. J. Wensley, E. H. Martindale, F. D. Hall, R. E. Ferris, A. M. Candy, L. J. Hibbard, Calvert Townley and C. M. Davis, with closure by S. T. Dodd and N. W. Storer.

SPRING MEETING OF ENGINEERING SECTION, NATIONAL SAFETY COUNCIL

The Engineering Section of the National Safety Council will hold a spring meeting in the Engineering Societies Building, New York, on Tuesday, April 27, ending with a dinner at the Commodore Hotel. The program includes the following subjects:

The Relation of Safety to Engineering Efficiency.
Safety Education in Engineering Colleges.
Safety Standards.
The Engineer's Place in the Modern Industrial World.

The list of speakers will include engineers of prominence in the engineering world as well as in the safety movement.

To bring the safety movement into closer touch with the engineering societies and the engineering profession in general is the principal purpose of the meeting. A cordial invitation is extended to all members of the A. I. E. E. to attend the morning and afternoon sessions, and particularly the dinner at the Commodore Hotel.

JOHN FRITZ MEDAL AWARDED TO ORVILLE WRIGHT

The John Fritz Medal Board of Award, composed of representatives of the national societies of Civil, Mining, Mechanical and Electrical Engineers, met on January 16, 1920, and awarded the medal for 1920 to Mr. Orville Wright "Fro achievement in the development of the airplane."

The presentation will take place Friday May 7, at 8:30 p. m. in the Engineering Societies Building, 33 West 39th St., New York. The principal speakers will be Maj. Gen. George O. Squire, Chief Signal Officer, and Col. Edward A. Deeds of Dayton, Ohio. Presentation will be made by Mr. Ambrose Swasey, Mr. D. B. Thayer, Chairman of the Board of Award, presiding.

The medal has been awarded in earlier years to:

Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas A. Edison, Charles T. Porter, Alfred Noble, Sir William Henry White, Robert Woolston Hunt, John E. Sweet, James Douglas, Elihu Thomson, Henry Marion Howe, J. Waldo Smith, George W. Goethals.

STUDENT BRANCH OF A. I. E. E. AT UNIVERSITY OF PENNSYLVANIA

With the recent formation of the student branch of the American Institute of Electrical Engineers at the University o fPennsylvania, Philadelphia, a plan has been developed to stimulate interest in the activities of the branch and to include in these activities all the students in the Electrical Engineering Department of the University.

The Seminar hour, formerly attended only by Senior students has been modified to include Freshmen, Sophomore and Junior as well as the Senior students. These Seminar hours are part of the required curriculum, and are, at the same time, regular technical sessions of the Institute student branch, being presided over by the Chairman of the branch, although the preparatory work on papers is under the direct supervision of the instructing staff.

Occasional evening meetings of the student branch are held which are of a social nature in distinction to the technical sessions. By this general plan, the interest in the Seminar work has been greatly stimulated and conversely, the technical sessions of the student branch have been reduced to a most effective status, with an enthusiasm and activity seldom possible in the usual manner followed in the conduct of branch meetings. These combined Seminar and branch meetings are attended regularly by about 125 students of the four classes exclusive of the instructing staff. The latter, while taking no part in the supervision of the meetings, frequently take part in the discussion which follows each paper.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

MILITARY AFFAIRS COMMITTEE

Military Policy of U. S. and Relation thereto of Technical Men

The Military Affairs Committee created by Engineering Council submitted the following communication to Council under date of February 26.

1. We believe it of vital national importance that sound Military Legislation should be enacted during the present session of Congress.

2. Effective provision for national defense with an adequate, organized, trained army and navy, sufficient to discharge our national and international obligations, is essential to security and stability, which must be present if our country is to go forward in constructive activity and achieve its possibilities as a nation.

3. The training of the entire youth of the nation and the establishment of organized reserves are indispensable provisions for national defense. With an adequate, organized citizen force, so that a minimum of professional soldiers is required, that maximum protection is afforded with a minimum of expense.

4. The careful selection and training of personnel and their assignment, when reservists, to organized reserved units, are vitally important to the efficiency of the technical services of the Army and Navy, and therefore essential to the proper preparedness of the individuals of the Engineering and allied professions and trades for the discharge of their constitutional obligations in national military service.

5. The full utilization of specially and technically qualified men and specialized industries has proved impossible where an organization was built up only after war had become imminent or had been declared.

6. The status of the membership of the National Engineering Societies with respect to all military matters, on which to base their plans for individual and collective preparedness, must remain indefinite until a military policy and principles of a military organization shall have been determined.

7. Therefore, We believe National security and stability can be assured only by application of the foregoing principles, in particular the principle of universal military training and the creation of organized reserves, above all in the technical branches.

We, therefore, recommend to Engineering Council that the President and Vice-President of the United States, the Secretary of War, the Secretary of the Navy, the Speaker of the House and the Chairmen and Members of the Military and Naval Committees of the Senate and the House be urged to incorporate the foregoing principles into any bills passed by either body for army or navy organization, and particularly the principle of universal training.

* * * *

We also recommend that each member of the Founder Societies be urged to study carefully the foregoing principles of military policy and in case, in the light of such study, he endorses said principles, to give his active support through letters to his Senators and Congressmen, or otherwise, to their incorporation in pending legislation.

These resolutions were submitted to the executive committee for approval and it was unanimously voted, to adopt the resolutions relating to the Military policy of the United States, prepared and recommended by the Military Affairs Committee.

NATIONAL SERVICE COMMITTEE

Extracts from Annual Report 1920

When the National Service Committee was constituted and the Washington office established, it was the writer's intention that the members of the committee would take a real part in the work of the Washington office and act in an advisory capacity. This plan failed. During the first few months, the writer endeavored to keep in touch with his committee and to make the members feel that they were really a part of the work. All of the members with one exception, responded promptly to all calls and demands. The trouble was that their responses were all *ex post facto*: too late to be of service. Things had to be done or omitted—they could not wait. Gradually the Chairman, in the press of his duties, forgot all about his committee and for months has not addressed them officially on any subject. The Chairman owes the members of the National Service Committee a profound apology, but at the same time he believes that his inattention has been excusable.

In one respect Engineering Council is to blame for this condition. Shortly after the National Service Committee was organized, Council passed a resolution to the effect that the Committee chairman should attend all regular meetings of Council. In this way a closer relation was set up between National Service Committee and Council than has perhaps been

enjoyed by any other committee of Council. The Washington office has been the adjunct of Council, rather than the headquarters of any committee. The Chairman of the committee has acquired the habit of applying direct to Council for instructions and advice instead of his own committee.

The name "National Service Committee" means nothing as the Washington office is at present conducted. It is recommended that the Committee be abolished. The writer believes, however, that the name "National Service" should be retained. In Washington it has been taken to mean just that which the words imply. In official circles it is understood to mean that Engineering Council offers service to the Nation, while in engineering circles it is interpreted as meaning that Council offers national service to the engineer. It is recommended that the name of the Washington office be changed to "National Service Department" and that the Washington representative be designated "National Service Representative."

It should be emphasized that the foregoing recommendations do not reflect on the members of the National Service Committee. It is apparent that, by reason of the peculiar conditions, a committee cannot function as such. The questions involved in the work are nearly always of so great importance that they must be taken direct to Council itself.

Review of Year

Engineers were very late in setting up a Washington office. Men in other vocations had preceded them in some cases by many years. About 150 national bodies have headquarters or branch offices in Washington. When Council's office was started, such a thing as organized engineering cooperation with the Government was unknown to the officials. Engineers were not regarded as interested citizens. At present, engineers are very well known at the Capital of the Nation and your organization has been rendering service there which seems to be appreciated more and more as the months go by. There are two aspects in which the Washington office may be viewed: First, it is the engineer's contribution to national welfare; second, it is the agency established by engineers by means of which they get all they can from the Government. If, in the opinion of Council, the former is the greater aspect then it will be of tactical advantage to give an expression to that effect from time to time. There is a branch office of a national engineering society in Washington the principal and frequently expressed purpose of which is to get everything possible for the engineer.

The more important matters undertaken during the year were as follows:

Mapping. Efforts to increase appropriations for U. S. Geological Survey mapping, made in June, 1919, were unsuccessful, although it is generally admitted that Council's effort to increase the appropriation was largely instrumental in preventing a marked decrease.

Increase in scope of the Geological Survey's topographic mapping next year has been undertaken by the Washington office with the cooperation of the Association of State Geologists and the Association of State Highway Officials. This work has involved the selection of some member of one of the four Founder Societies in each Congressional district of the country, who has been given the facts concerning mapping necessities and urged to undertake to interest the engineers and other parties residing within the Congressional district, so that the facts can be brought to the attention of the members of Congress in a way that will lead them to inform themselves more thoroughly concerning the needs. Just how successful this will be cannot now be determined. We are not optimistic however.

Our real accomplishment with respect to Government mapping has been the creation of a permanent Board of Surveys and Maps to which the supervision of all Government mapping has been given. This resulted from a letter from the Chairman of Engineering Council to the President.

The writer, as representative of Engineering Council and the four Founder Societies on a committee composed of unofficial organizations interested in mapping, has taken part in the preparation of a report to the Board of Surveys and Maps, which report has been submitted back to New York for approval. The principal features of that report are strong recommendations: (a) that all Government mapping be concentrated in one agency, and (b) that whenever any Government surveying party goes upon any area for purposes of mapping, however elementary, that party shall secure all the data necessary to a standard topographic map.

Appointments. The President has been urged to appoint engineers on the International Joint Commission and the Interstate Commerce Commission. There was failure in the first instance, and the result in the second has not been determined. Appointment was made in the latter case, but the President failed to consult with his appointee or ask him if it would be agreeable to present his name. The result was that the appointee has declined and the place is still vacant. The writer has made no effort to renew the request in favor of the appointment of an engineer.

Wages of Railroad Engineers. An attempt was made to secure favorable action by the Railway Administration on suitable increases in compensation of railway professional engineers. A hearing was secured before the Board on Railway Wages and Working Conditions. The American Association of Engineers was subsequently invited to take part in the proceedings. The result, so far as the Railway Board was concerned, was satisfactory, but the case was suddenly taken out of its hands. Regional Directors were instructed to use their judgment in such matters wherever compensation of railway engineers appeared to be inadequate. The writer has been informed by men in the Railway Administration who ought to know, that the real opponents to suitable compensation for professional engineers in railway work are the chief engineers; it was they who had the matter removed from the jurisdiction of the Board on Wages and Working Conditions and they who prevented the Railroad section of your Committee on Compensation from functioning. It has become apparent to some persons connected with the Railway Administration that the principal reason why professional engineers employed by railroads receive less compensation than round-house hostlers is that the chief engineers are reluctant to increase the engineers' wages and give no assistance to attempts made to achieve such a result.

Relations with Congress. The Washington office has been successful in its negotiations with Congress and with chairmen of committees having to do with engineering matters. Our failure in one instance to secure the interest of Congress in a certain piece of l gislation was due to the inertia of the very engineers in whose benefit the bill was proposed. At the close of the war, about 800 engineers were wrongfully deprived of remuneration for travel and subsistance, some of them severely so. Two separate appeals were sent out for facts concerning individual cases, but out of the 800 engineers known to have been so deprived only about 12 responded. Of course such a number is not sufficient to secure any enthusiastic action on the part of members of Congress.

The Department of Public Works. Even before the engineering and architectural societies of the country organized the National Public Works Department Association, this subject had become the overshadowing one in the Washington office, and, as indicated by the ratio of expenditures, it continued to be the principal item.

Since the last meeting of Council, the Public Works Association has held a most successful convention in Washington, the results of which in both legislative and financial respects have proved to be exceedingly tangible. Present improvement in the whole situation and the revival of interest now so readily apparent dated from that convention. On February 11, there

was a hearing before the Senate Committee on Public Lands on the Publics Works bill, at which expected opposition on the part of some bureaus and departments was conspicuous by its absence. The progress of the public works principle and the bill introduced into Congress is regarded by many members of Congress as altogether remarkable, coming as it does at a time when Congressional attention is being given almost exclusively to matters of urgent necessity, resulting from war.

Work Since December Meeting of Engineering Council

Among the important activities of the Washington office since the last meeting are:

1. The circularization of Government contractors for the purpose of securing comments and criticisms on the form of Government contracts and the interpretation of specifications, all leading up to a report on the reasons why Government work is avoided by the majority of contractors. The utility of this study will be two-fold. It will be used first by the Committee on Types of Government Contracts, and, second, by the Public Works Department Association in connection with its showing before Congress on the necessity for a standardization of Government contracts and specifications.

2. The Washington office has, on invitation, been assisting the Chairman of the new Board on Surveys and Maps, created by Executive Order, in the selection of engineers representing outside organizations for membership on the several committees appointed by the Board of Surveys and Maps.

3. In response to suggestions by the Washington office the Chairman of Engineering Council sent a letter to the Secretary of War advocating the early publication of the report of the Board of Review on War Department Construction. This letter was delivered by hand at the office of the Secretary of War and since such delivery the matter has been followed up, with the result that we are informed that the entire report will be printed as a part of a hearing before a committee of Congress.

4. The proposed Boston-Washington super-power investigation has been the subject of follow-up work. Letters were sent to 142 organizations in the region affected, calling attention to the necessity for activity in the attempt to secure a suitable appropriation as a part of the Sundry Civil Bill. This work has been carried on in conjunction with W. S. Murray. Agreement as to the representation to be made to the Appropriations Committee of Congress has been effected and it is asked that approval be given by Engineering Council. It is suggested that the committee of Council to present the matter before the Appropriations Committee consist of W. S. Murray, D. C. Jackson, L. P. Breckenridge and M. O. Leighton.

5. An appointment for a hearing before the House Committee on Military Affairs was secured on behalf of Council's committee on the maintenance of the Signal Corps of the Army. Col. J. J. Carty and H. W. Buck appeared for Engineering Council. The undersigned has rarely seen a committee of Congress so thoroughly interested in a technical matter, and in his opinion, the appearance of Col. Carty and Mr. Buck contributed largely to the prestige of Engineering Council at the Capitol.

6. Patent legislation is proceeding through the regular legislative routine about as fast as can be expected. The bill providing increased salaries for the personnel of the Patent Office has been reported out of committee and awaits a hearing before the Committee on Rules before receiving a place on the House calendar. This hearing will be held February 24. The bill providing a Court of Patent Appeals and the bill which is aimed to make the Patent Office more efficient have been reported by the subcommittees of the House Patent Committee and will be reported shortly.

7. On several occasions the Washington office has been asked to look into legislation which proposes to change the standards in the country from the English to the metric system, especially by a call from the Secretary of the Institute of Weights and Measures, who is in Washington combating this proposed legislation. The Secretary of the Institute has been introduced to the heads of Departments in the Government directly interested; your representative has been careful at all times not to express an opinion for Engineering Council.

8. The office has participated in society affairs in Washington and as a result of the enterprise and foresight of A. C. Oliphant plans are under way whereby the local engineering society, together with the sections and chapters of national societies, including the Civil, Mechanical, Electrical, Mining and Metallurgical, Automotive, and Chemical Engineers and the Naval Architects will unite in the joint organization.

9. The general work of the office has increased at about the same rate as previously. For instance, inquiries answered since the last meeting of Council number 81, as compared with 63 during the previous two-month period.

(Sgd.) M. O. LEIGHTON,
Chairman.

COOPERATION OF NON-FEDERAL ORGANIZATIONS WITH THE BOARD OF SURVEYS AND MAPS

When the meeting of the members of the Board of Surveys and Maps with representatives of outside organizations was over on March 9th, everyone who was in attendance agreed that a long step had been taken toward improvement of Governmental efficiency. This meeting was called by the Chairman of the Board, Mr. O. C. Merrill, as a result primarily of the report of the Interdepartmental Conference on Topographic Mapping, dated September 30, 1919, and in accordance with an Executive Order dated December 31st, 1919, which created the Board of Surveys and Maps, and directed it to receive advice and counsel of outside agencies interested in the mapping work of the Government.

The report of the Committee of Representatives of the outside organizations interested in Government mapping was presented by M. O. Leighton as representing the member societies of Engineering Council and as secretary of the Committee, which membership includes the above organizations and the American Association of State Highway Officials, Association of American State Geologists, National Research Council, Association of American Geographers, American Geographic Society and Geographical Society of America.

In introducing this subject Mr. Leighton warned the Board that while efficiency and economy in centralized mapping operations were most commendable, there are certain occasions when strict application of the accepted principle would deprive some Government agency of its mapping prerogatives. The consideration of the Board in such cases would have to be in a large degree judicial and representatives of the interested department should be disqualified from participating in decisions affecting that department. Further, it was suggested that a plan should be adopted by which cooperating non-federal agencies could have a voice in the determination of the manner and place of disbursement of their contributed funds.

The following recommendations were then made with appropriate amplifications and explanations:—

1. That the Board of Surveys and Maps adopt a policy that shall direct itself exclusively to the best interests of the Government as a whole, disregarding wherever necessary, departmental and bureau precedents, pride or authority of official prerogatives; that the mapping activities of the Government be centralized, and for the present the U. S. Coast and Geodetic Survey continue its functions of fundamental control, while the Geological Survey or some outgrowth or reorganization thereof become the general and the final map-making agency.

2. That the Board of Surveys and Maps formulate a consecutive plan based on the idea of centralized map making activity, which shall cover the mapping work of the Government and unite the organizations now constituting the Board into a cooperative effort to secure congressional approval, which plan shall provide for the completion of the standard topographic map of the United States within a specified time.

The report contained comments concerning the following special features of the conference report:—the preparation of skeleton maps of various scales, which would decrease the costs and increase the efficiency of all Government offices and outside agencies concerned, so as to more than compensate for the loss of strong self-contained organizations; methods of distribution should contemplate the size of additions, costs, methods of distribution and should eliminate the "make ready" costs as well as making the maps available with the least amount of effort on the part of the public; suitable maps for educational institutions should be provided and instructions issued for their utilization with appropriate courses. Assistance should be given in the improvement of popular maps and atlases; coordination of Federal and Non-Federal datum reference points should be effected as soon as practicable. The Board should not depart from its standardized maps except by special agreement with the interested agencies whenever the need of such maps arises.

Following the presentation of the above report, the need of a general topographic map of the United States and means by which its preparation may be expedited was covered from the highway standpoint by a representative of the Director of the Bureau of Public Roads; from the railway standpoint by A. C. Baldwin, Vice-President of Illinois Central Railroad; from a military standpoint by C. O. Sherrill, Colonel, Corps of Engineers, U. S. Army; and in general by George Otis Smith, Director of U. S. Geological Survey, and Major William Bowie, Chief of Division of Geodesy, U. S. Coast and Geodetic Survey. The extent and means of cooperation between the Board and other agencies was covered by Mr. A. D. Flinn, Secretary of Engineering Council; Edwin F. Wendt, District Engineer, Interstate Commerce Commission; F. W. DeWolf, State Geologist of Illinois. The public needs which a central information mapping office may serve was covered in detail by E. B. Matthews, Chairman of Division of Geology and Geography, National Research Council.

It will be recalled that the development of this Board of Surveys and Maps through the Interdepartmental Conference on Topographic Mapping was brought about largely by action of Engineering Council in bringing the chaotic mapping conditions in the Government to the attention of the President, with recommendation that such agency be formed. The developments of this last meeting indicate that the Board will not sidestep the task of making over these vast departmental operations. During the discussion that followed the report, the Board was repeatedly assured of real cooperation from outside organizations provided they would approach the committee already formed or such new committees as were deemed wise, with well defined problems to be solved.

CURRENT ENGINEERING TOPICS

STATUS OF THE PLAN FOR DEFERAL BUDGET

After the House of Representatives passed Mr. Good's Budget Bill to the members of the Select Committee on the Budget in the Senate, each took this question up separately and made recommendations for extending and changing the bill to meet their ideas.

A new bill has been recommended and agreed upon by the Senate committee, so that it will be reported to the Senate calendar early in April.

Engineers will recognize that this is important legislation, vitally effecting Government reorganization,—it goes along hand in hand with the engineers' bill,—Jones-Reavis Bill to create a National Department of Public Works. The plan for departmental budget is embodied in the proposed Public Works Department so that the new department when formed will contemplate at least the fundamentals proposed in this national budget legislation.

CONTINUATION OF THE NATIONAL SCREW THREAD COMMISSION

A resolution passed the House of Representatives March 1st, amending the act that created the National Screw Thread Commission, so that the life of this commission will be extended for an additional period of two years from March 21, 1920.

The resolution has been referred to the Committee on Standards, Weights and Measures in the Senate, and although meetings have been called to consider this measure, Senator James M. Reed, chairman of the committee, has been unable to get a quorum present. It is contemplated that this measure will receive early action as soon as the Senate is able to clear up its present calendar.

ARMY REORGANIZATION BILL

The Army Reorganization Bill passed the House March 19, providing for continuation of Chemical Warfare Service and a strong Signal Corps. The amendment to maintain separate Construction Corps which had been passed March 12, by a vote of 135 to 74, was reversed by a vote of 168 to 158. The present status of the bill will retain Construction Corps and Motor Transport Corps in the Quartermaster Corps.

MACHINE TOOLS FOR THE FRENCH AND BELGIAN COMMISSIONS

Some manufacturers have been informed that private credits on machine tools required by the French and Belgian Commissions could be arranged through the War Department. This is not the case and the War Department has issued advice that it is in no way connected with negotiations which are taking place between these Commissions and private manufacturers. The War Department has, however, agreed to permit the French to take such surplus tools as they require on credit. The Director of Sales in the War Department has pointed out that his office is anxious to be of service to the American manufacturers, the French and Belgian Commissions in rounding out their needs, but private purchases of the Commissions can in no way be financed by the Government. The French Commission alone has purchased machine tools in the United States valued at over $1,000,000 and much heavier purchases are expected to follow shortly. Most of these purchases were made through the New England districts, whereas the West has supplied comparatively few. An invitation has been extended by the St. Louis interests, asking the Commission to visit that city where considerable quantities of tools are available.

Such sales as the War Department has been able to make the Commission have all been at domestic prices, the purchaser paying for crating, loading and transportation.

Complete lists of additional tools required by both the French and Belgian Commissions may be obtained from the National Service Department of Engineering Council.

STATUS OF WATER POWER BILL

Two important points of difference existed between the House and Senate conferees on the Water Power Bill when they adjourned March 9th for a period of at least two weeks. The adjournment was taken to await the return to Washington of Representative Taylor of Colorado, and permit Senators Jones and Smoot to devote some time to the Merchant Marine and Executive Bills, respectively, both of which are now pending.

Agreement may be expected shortly after this issue goes to press. Hope was expressed that the conferees would get together after a short discussion but this hope was not realized, although the friends of water power development regard the situation as very satisfactory. The remaining points of difference, which have delayed agreement, are those pertaining to license charge and recovery and the proposal to have an Army engineer as Executive Secretary. The strong opposition to

this plan will probably result in placing a civilian in that office with the authority to have an engineer officer detailed to assist in the work.

The power project for Great Falls on the Potomac River, which carries an appropriation of $25,000,000 and was placed in the bill as a rider by the Senate, was eliminated in conference. No announcement was made concerning the other items, but it is believed that the Newland's investigating provisions will be eliminated.

A CALL TO INSTITUTE MEMBERSHIP TO ASSIST IN PATENT LEGISLATION

As a result of the efforts of Mr. Edwin J. Prindle and his colleagues, the Nolan Patent Bill was put on the House calendar for March 5th. It passed the House of Representatives by a substantial margin that day.

Mr. Prindle is chairman of the Patent Committees of both Engineering Council and National Research Council. It will be recalled that extensive hearings were held before the House Patents Committee so that the case presented to the Judiciary Committee consisted simply in urging immediate consideration for the Nolan Patent Bill. About sixty engineers, all of whom were members of the Founder Societies or representatives of organizations using the Patent Office extensively, supported Mr. Prindle. When the hearing was over, the chairman of the Judiciary Committee told these men that it had been the most satisfactory hearing held by his committee in over ten years and that the thorough disinterested manner in which the engineers had presented their case assured early action in the House. This assertion was borne out when the House passed the bill a few days later.

The bill (H. R. 11984) as it passed the House provides for an increase in salaries and staff of the Patent Office and certain other amendments to the present statutes. The salaries of the principal Examiners are to be raised from $2750 to $3900. The bill also authorizes the courts to assess general damages under certain conditions in infringement suits.

The members of the Patents Committee of Engineering Council have expressed their opinion that it is of the utmost importance that the force and salaries of the Patent Office be promptly increased.

The bill is now before the Senate Patents Committee where it is intended to hold short hearings and send the bill on its way as soon as the Treaty Legislation can be disposed of.

Please write immediately to your Senator urging that he vote in favor of the bill, and thus aid in obtaining a much needed relief.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

ILLUMINATING ENGINEER for work in industrial lighting problems for contracting and electrical engineering firm. Man with wide industrial and some sales experience desired. One who would consider compensation on salary and commission basis, preferred. Location Toronto, Canada. Z-584.

MAN TO TAKE CHARGE OF SHOP building motors for phonographs. Should be capable of taking entire charge of production and bringing same down to best and most economical commercial manufacturing basis. Location Brooklyn. Salary $5000 to start, and if man demonstrates capacity and ability to handle job satisfactorily, will gradually increase this to $10,000. Z-587.

ENGINEER to handle questions of power plant operation including electrical generation, refrigeration, compressed air and vacuum pumping and boiler plant. Location New York at present. Z-604.

ELECTRICAL DRAFTSMEN and Designers for work in connection with transmission lines, substation equipment, switchboards, motor control equipment, etc. Location Ohio. Z-613.

PERSONAL ASSISTANT to chief engineer of power and electric company. Would have to do calculating on special electrical engineering problems. Man pretty well versed in mathematics and electrical calculations desired. Practical experience not necessary but applicant must possess good sound judgment and initiative. Location Mass. Z-625.

ELECTRICAL ENGINEER for firm of Consulting Engineers. Requirements; five years minimum experience since graduation from technical school embracing design and preferably also construction and operation of power plants, transmission, and distribution system. Duties—largely office work on design although field inspection and tests are demanded occasionally. In making application give detail record of experience including personal data, salary required, date for reporting. Commensurate with value of experience salary range will be from $252 to $333 per month. Mees & Mees, 310 Trust Bldg. Charlotte, N. Car. Z-627.

LARGE NEW ENGLAND MANUFACTURER of electrical apparatus wants young men with some experience in drafting who desire to improve their opportunities. To such as have good high school education and some technical training but who for some reason were not able to complete their technical course, we offer opportunity to work as draftsmen at good wages and at the same time, without expense, attend courses of instruction to prepare them for positions here as calculators or desingers of electrical apparatus or specialists in sales organization. Location Mass. Z-628.

SALES ENGINEER young man with some college or technical school education to ultimately be assigned to sales force, after taking course at factory in engineering department. General laboratory and experimental work to begin with, together with computing of layouts, and proposals for lighting, costs, and maintenance. This will take year or little longer and will give candidate full opportunity to learn lamps thoroughly and be conversant with their uses and ultimately fit him for outside sales engineering work. Salary $100-125 per month to start. Location New Jersey. Z-658.

ELECTRICAL DRAFTSMEN for substation work; (B) TRACER for same line work. (C) ASSISTANT ELECTRICAL ENGINEER for squad boss on substations work; Must have good personality. Location vicinity of New York City. Z-670 A-B-C.

FIRST CLASS ELECTRICIAN. Salary $225 gold at the beginning, with transportation. Spanish desirable but not essential. Address C. C. Hoke, Mapini Dgo, New Mexico. Z-677.

EXPERIENCED SWITCHBOARD OPERATOR for hydro-electric station. Salary $115 per month, eight hours, location New England. Give experience, age, references, whether married or single. Z-678.

ENGINEER MATHEMATICIAN AND PHYSICIST; salary commensurate with ability. Location Mid le West. Z-681.

ELECTRICAL, MECHANICAL, AND CHEMICAL ENGINEERING MEN of 1920 class or those that have not been away from college more than two or three years at the most. Company is planning considerable expansion in incandescent lamp industry within next five years and believe that opportunity for advancement for engineering men will be particularly good. Starting salary will probably range from $1500 to $1800 per year depending entirely upon experience and training. Location New Jersey. Z-684.

DRAFTSMEN to lay out wiring for lighting and power work for various types of buildings. Must be familiar with this kind of work and have had experience, either with some electrical engineers or with some electrical contractors. Location New York City. Z-687.

EXPERT ACCOUNTANTS; must be between ages of twenty and forty, and have had considerable accounting experience, or have graduated from an accounting school. Salary commensurate with ability. Location New York State. Z-724.

ELECTRICAL ENGINEERS who have had technical training and who are familiar with application of electricity in coal mining, power plant operation, and who have had experience in building up an organization. Duties will include maintenance of large amount of electric equipment in the mines, supervision of 5,000 KW Generating Station, and handling of the entire electrical organization at colliery. Salary $3,300 per year. Location Pennsylvania. Z-727.

RECENT GRADUATE ENGINEERS or those but one or two years out of college for apprenticeship course in manufacturing plant lasting from six to nine months. Broad gauge men desired. Will pass through various departments of plant to get an insight into the business and will then be assigned to production, cost, or management engineering work. Salary $125 per month with increase to $150 after 9 months. Location Penn. Z-736.

RECENT GRADUATES in mechanical, electrical or chemical engineering. Good future. Salary $2500 and expense. Location India. Z-737-B.

GRADUATE ELECTRICAL ENGINEER for installation, maintenance and selling of an electrical neutralizing devices for printing plants. Must not be afraid of work, and must also join union in order to do installation work. Location New York City with some traveling. Z-741.

INSTRUCTOR IN MATHEMATICS for next school year at Brown University. Essential that candidate have had either experience in teaching or good mathematical. Engineering experience would be valuable addition to man's qualifications. Should be young man imbued with high ideals and possessing some social graces. About fourteen hours of teaching would be expected. Salary twelve to eighteen hundred dollars for first year. Location Providence, R. I. Z-761.

GENERAL SUPERINTENDENT at least 35 years of age, with extensive experience along executive lines to take charge of operation of electric railway, power and light company serving from 12,000 to 15,000 customers, and operating about 100 miles of street railway. Need not necessarily be a technical graduate but such training would be of advantage. Must have had railway and power and light experience, but above all must be an excellent manager and executive. Location Pennsylvania. Z-801.

ENGINEER EXPERIENCED in electric railway roadbeds and equipment. Must have had technical and practical experience and be at least 35 years of age. Position is one to be created in an organization operating 100 miles of street railways and serving 12,000 to 15,000 customers, with light and power. Location Pennsylvania. Z-802.

ASSISTANT ELECTRICAL ENGINEER for large manufacturer of excavating machinery. Duties will include application and arrangement of electrical equipment, such as—motors, magnetic control, transformers, motor generator sets, wiring, etc. to electric shovels, dragline excavators and dredges. Technical man with electrical and mechanical experience desired. Salary $125-175. Z–817.

ELECTRICAL ENGINEER; permanent position open for graduate engineer, preferably Canadian familiar with Ontario. Intimate knowledge of interurban electrical railway equipment and operation essential. Apply Employees Relations Department, Hydro-Electric Power Commission of Ontario, 190 University Avenue, Toronto, Canada. Z-818.

YOUNG ENGINEER if sound technical training desired in connection with the development of new high frequency electrical apparatus. Good grasp of physical and mathematical fundamentals important. Signal Corps experience useful. Permanency assured. Location New York City. R-2405.

JUNIOR RESEARCH ENGINEER; a long established industrial organization in a rapidly expanding field has an attractive opportunity for a young man of first-class ability and thorough training in electrical engineering or technical physics. Postgraduate training desirable but not insisted upon. Prospects limited only by ability. Salary proportionate to education and record. Location New York City. R-2406.

DEVELOPMENT ENGINEER; young engineering graduate wanted for experimental development work on electrical apparatus. Distinctive opportunity for young man of energy, resourcefulness and supervisory capacity to grow with new engineering developments of a fundamental nature. Salary determined by qualifications. Location New York City. R-2407.

SALES ENGINEERS; young men, preferably with mechanical or electrical education and training, although any technical graduate would be considered. Not much sales experience necessary, but men must possess sales potentiality. Salary $150 up depending upon, qualifications. Location New York City. Application by letter with which should be enclosed recent snapshot. Z-193.

ELECTRICAL ENGINEER experience in design of D. C. Generators and Motors of medium and large size. Must be technical graduate, and have had about five years design experience. Permanent position with opportunity for advancement for qualified designer. In applying, state education and practical experience since graduation. Location Pennsylvania. Z-340.

RECENT GRADUATES OF MECHANICAL OR ELECTRICAL ENGINEERING COURSES for engineering work connected with production of electrical and mechanical devices. Send application to Mr. J. C. Wilson the Cutler Hammer Mfg. Co., Milwaukee. State training, experience in industrial plants, if any, references and other information concerning yourself. Z-476.

UNIVERSITY OF WISCONSIN, ELECTRICAL ENGINEERING DEPARTMENT, desires to appoint an assistant or associate Professor of Electrical Engineering qualified to assume charge of the Central Station and Electric Railway Courses. An experienced engineer who has carried on investigative work resulting in contributions to the art is desired. R-2080.

ELECTRICAL ENGINEER with experience on transformer design. Splendid opportunity. State age, education, and practical experience when applying. Z-827.

MEN AVAILABLE

Notices are published in this column subject to the following regulations:—

1. Copy should be limited to 45 words.
2. The form should be such that the initial words indicate the classification.
3. Copy should be on hand by the 15th of the month preceding date of issue.
4. Notices are not repeated in consecutive issues.
5. Only notices of society members (or those introduced by society members) will be published.

GRADUATE MECHANICAL ENGINEER; married, twelve years of exceptional broad practical experience, technical apprentice machinery course, shop, office, sales, factory estimating, inspection, salvage, inventory and appraisal; purchasing and export experience; inspection and testing; erecting engineer; production engineer; appraisals expert. Familiar with Latin America and its people. Salary depends on location. Available thirty days notice. E-2097.

ELECTRICAL-MECHANICAL MAN; experienced as chief electrician, chief draftsman, assistant mechanical engineer, plant engineer and head of department of instruction. Understands manufacturing, installing and operating field or small electrical-mechanical machines. Correspondence school and Alexander Hamilton Institute courses. American; married; 28 years; prefer Eastern states, would consider Middle West. E-2098.

ELECTRICAL ENGINEER; technical graduate; age 31; experienced in design, construction, operation and maintenance of large hydro-electric plants; high tension transmission systems; high tension transformer and switching stations; rotary converter substations and large industrial electrical installations. Location unimportant. Salary $4000. Available on 30 day notice. E-2099.

INDUSTRIAL PHYSICIST; age 29, married and in excellent health, desires position as chief physicist, or as assistant to physicist of national note. A.M. and Ph.D. degrees in physics and mathematics. Two and one half years practical research in engin ering laboratories of large corporation. Present salary $300. Available 30 days notice. E-2100.

EXECUTIVE-ELECTRICAL ENGINEER; four years factory management and industrial investigation, fourteen years public utilities and industrial engineering, including syndicate operation of small utility companies. Technical graduate, age forty two. Available on reasonable notice. Minimum salary $4000. Positions with future possibilities, only will be considered. E-2101.

ELECTRICAL AND MECHANICAL ENGINEER; age 42; 19 years experience on high and low tension apparatus, switching equipment, sub-stations and underground work. Last 10 years supt. in charge of construction, maintenance, and operation of 160,000 H. P. plant. Has also some industrial plant experience. Available any time. E-2102.

FACTORY MANAGER; of auto tire and tube plant desires to connect with well financed company manufacturing similar line. Age 33 years, graduate Mass. Institute of Technology. Thorough knowledge of rubber compounding and manufacturing methods. Excellent references. E-2103.

AMBITIOUS YOUNG MAN; age 23, electrical school graduate, with one year of construction and repair and with three years of marine and maintenance experience, desires opportunity which may lead to executive position. Associate. E-2104.

ASSISTANT ENGINEER; age 25, married; technical education; 5 years experience in contracting, testing and construction. Last two years with electric traction company on substation construction work, comprising general supervision of switchboard construction. E-2105.

TECHNICAL GRADUATE; age 29, desires position as assistant to Electrical Engineer or Superintendent. Seven years experience in the maintenance and operation of power houses. E-2106.

ELECTRICAL AND MECHANICAL ENGINEER; 20 years' experience; is capable designer and has inventive ability. Can take charge of or organize efficient drafting force; specialties are elevators, motor control apparatus and automobile equipment. Location, Newark or Vicinity. Age 41. Minimum salary $4000. Excellent references. E-2107.

SALES EXECUTIVE; 43 years old; married; 20 years successful sales experience, 15 years in electromechanical lines. Competent sales and business executive, special experience in motors, generators, storage batteries and applications. Prefer location in Philadelphia or Chicago. Formerly manufacturers' agent in Chicago. Now in War Work. Available May first. E-2108.

ELECTRICAL ENGINEER; graduate in engineering, also Emerson Efficiency course; 16 years experience as assistant or chief electrical engineer; specialist on industrial power systems and transmissions up to 66,000 volts including design, construction and operation, desires engagement as electrical engineer with industrial concern or as industrial power specialist with power company. E-2109.

YOUNG ELECTRICAL ENGINEER; university graduate; experienced in hydro-electric power plant operation and pole line construction, desires position with hydro-electric power company where there is good chance for advancement. Available in July. E-2110.

ELECTRICAL ENGINEER; technical graduate, age 27, married; at present employed in consulting engineering office, desires change. Four years varied experience covering tests of electrical equipment, installation, maintenance, and calibration of electrical measuring instruments; standardization work; investigations of transmission and distribution systems. Location preferred, East. Minimum salary $2,100. E-2111.

ELECTRICAL ENGINEER; age 28, married; desires position with commercial or engineering establishment. At present Asst. Professor of Electrical Engineering, 1915 graduate. Five years valuable experience; Westinghouse test. Work considered where engineering training can function and where future exists. Location anywhere, middle west perferred. Available June 15. E-2112.

GRADUATE ELECTRICAL ENGINEER; M. I. T. 1918, age 25; Associate Member; 14 months General Electric test work, including A. C. and D. C. rotating machinery, steam turbines, transformers, and control apparatus. Desires position with power company. Available at once. Location unimportant. E-2113.

GRADUATE ELECTRICAL ENGINEER; specialty radio engineering with one year's experience in radio inspection, and installation of commercial equipment, and two year's experience as instructor in radio theory desires position after July. Associate member A. I. E. E. and I. R. E. Salary $150 to $175 depending upon locality. E-2114.

ELECTRICAL ENGINEER; technical graduate of highest standing, one year as second lieutenant, Signal Corps, one year in development work for electrical manufacturer; desires connection where personality as well as technical ability can be capitalized, preferably in sales organization of electrical manufacturer. Salary not less than $2400. E-2115.

ELECTRICAL ENGINEER; graduate 1912, desires position in hydro-electric power development, with consulting engineers, or in industrial plant. 8 years experience with large industrial corporation having extensive hydro-electrical generating, rotary convertors and distribution systems. Age 31, married; minimum salary $300 per mo. E-2116.

ELECTRICAL ENGINEER; A. B. and E. E.; seven years experience in practical work, covering central station, substation and isolated plant construction and maintenance; two years head of department of electrical engineering in state university, desires teaching or commercial position. Age 32, married. Minimum salary $3500. Present salary too low. E-2117.

ELECTRICAL-MECHANICAL-HYDRAULIC SALES ENGINEER; graduate degree Ph. B. in E. E.; 22 years in field as chief engineer and manager salesmen etc. for domestic or export. Foreign station acceptable; 2 years in U. S. Engineers; officer in charge constru tion in France, 18 months experience in pumping, steam, hydraulic and all mechanical lines. E-2118.

ELECTRO-MECHANICAL ENGINEERING GRADUATE; 25 months General Electric Co. test; 20 months inspection work at large shipbuilding plant; desires position in or near New York City as sales or assistant industrial engineer with good opportunity for advancement. Available on 30 days' notice. Salary $200 per month. E-2119.

TECHNICAL GRADUATE; two years G. E. test; eighteen months construction; one year second lieutenant signal corp; one year electrical instruction in large middle western university; desires position as works electrical engineer, central station superintendent, or assistant factory manager. Salary $2400. Available June 1st. E-2120.

INDUCTION MOTOR DESIGNING ENGINEER; thirty-four; ten years actual experience with four most successful motor manufacturers, now open to offer. If you need a real engineer, conversant with every phase of the game, theoretical and practical, do not pass this up. Salary about $4000. E-2121.

ELECTRICAL ENGINEER; technical graduate; five years in charge of transmission, distribution, substation and switchboard design and construction; three years with large public utility company; at present in charge of electrical reconstruction of large property, desires position with progressive organization that is willing to pay for results. Salary $3600 to $4000. E-2122.

PROFESSOR OF ELECTRICAL ENGINEERING; wishes to make change in position at end of present school year. Will consider teaching or commercial position in any section. Age 35. Broad training in engineering, research, and teaching. At present head of an electrical engineering department. Minimum salary $4000. E-2123.

ELECTRICAL ENGINEER; age 30, technical graduate with 7 years experience in public utility work from test to department supervision. Experienced in construction, operation and maintenance of steam and hydro-electric plants, distribution and transmission systems. Available on reasonable notice. E-2124.

SUCCESSFUL ELECTRICAL ENGINEER; of several years practical and teaching experience desires teaching position with considerable amount of executive work. Age 35. Member. Salary $3200. E-2125.

ELECTRICAL ENGINEER; graduate; married; excellent experience in electrical and efficiency engineering. Calculation, power plant and transmission construction, large motor applications, transportation, investigations, reports and installations of mining and industrial power projects. Good executive. Services available on short notice. Correspondence invited. E-2126.

SALES ENGINEER; age 36; technical education, considerable practical experience, wiring layout and installation; design and manufacture of conduit fittings, wiring devices, lighting equipment and artistic fixture parts. Broad selling and advertising experience to electric dealer, jobbing and central station trade, industrial, household, marine and railroad consumers. Now in manufacturing business. E-2127.

EXECUTIVE; broad engineering and business esperience, age 34, university training, engineering and law; conversant with wide range, large construction and operation work, also machinery, their specification and manufacture. Experience shop work, cost accounting, purchase, sales and office management. Accustomed vast amount detail. Now holding responsible position. E-2128.

ELECTRICAL ENGINEER; technical graduate, age 43, open for position. Familiar with power plant work, power transmission and application. Experienced in installation, operation and maintenance of steam and electrical machinery and electric car equipment. Able to take hold and get results. E-2129.

ELECTRICAL ENGINEER OR CHIEF ELECTRICIAN; age 33; married; trade school graduate; experienced on estimating, installation and maintenance of electrical machinery 75 H. P. and under, transmission up to 11000 volts; duct systems and electric arc welding; present position 3 years at $2000 per year as Inspector on large steam and electrified railroad. E-2130.

RESEARCH MAN; university graduate electrical engineer. Teaching, G. E. test and experimental experience. Practical ability in research procedure and initiative in applying principles of physics to new situations. Now engaged in research work on factory processes for large manufacturing company. Desire middle western location. Salary $2400. E-2131.

ELECTRICAL ENGINEER; with two years experience in designing D. C. motors, desires position either designing or operating. Salary $2500 to start. E-2132.

ELECTRICAL ENGINEER; desires position in Eastern Ontario, Canada. At present chief electrician large by-product coke plant. Ten years general steel mill construction and operating experience. Thorough knowledge of motor repair work A. C. and D. C. and magnetic control. Ability to handle men; also to specify and purchase electrical equipment. Salary $3000. E-2133.

ELECTRICAL ENGINEERING GRADUATE; 1919 B. S.; age 23, single desires position in engineering department of concern manufacturing electrical machinery or power supply company. Two years testing experience on D. C. machinery. Salary $1500. E-2134.

ENGINEER; of twenty-five years experience, technical graduate (M. E., Sc. D.) who has been teaching during past ten years, desires to return to commercial field. Broad experience along lines of power-plant and machine design. Ability to take responsible charge of high grade work. E-2135.

SALES ENGINEER AND EXECUTIVE; technical graduate; age 30, will consider high grade proposition to establish connections with right kind of successful men. 10 years experience, consisting factory work, testing, construction, central station, railway, industrial plant and electric furnace, sales. Available on short notice. E-2136.

ELECTROCHEMIST; experience in manufacture of metal, metal-graphite, graphite, and carbon brushes, small electrodes and other carbon products. Technical graduate with ten years experience. Capable of taking entire charge of factory. Can design special machinery and furnaces. At present employed. Single, age 31, will go anywhere. E-2137.

GRADUATE ELECTRICAL ENGINEER age 28; single; wishes to become associated in work of commercial character, sales engineering preferred. Six years experience, including two years operation and maintenance of electrical equipment, four years office engineering work on power equipment. Executive ability; good correspondent; retentive memory. Available 30 days' notice. E-2138.

TELEPHONE ENGINEER; 30 years old. Six years with Western Electric Company. Experience includes student course, experimental and development work on semi-automatic and manual systems. Salary $2500. Services available in thirty days. Location desired, California. E-2139.

EXECUTIVE ENGINEER; employed ten years by leading manufacturer as research, design, and application engineer desires to become affiliated with active sales or works organization where broad engineering experience will serve as basis for larger activities. E-2140.

MECHANICAL OR PLANT ENGINEER; technical graduate, excellent executive, successful in handling all classes of men, diplomatic and tactful. 18 years experience in electrical and mechanical engineering including installation and maintenance; industrial plant, power, heating and lighting layout; organization and production engineering and purchasing. E-2141.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—John McF. Fisher, Arapoho, Oklahoma.
2.—J. P. Gailunas, 100½ Van Couver Avenue, Detroit, Mich.
3.—Lincoln Nissley, 1213 Pioneer Bldg., St. Paul, Minn.
4.—George L. Sewell, Porter Bros., Norfolk, Va.
5.—W. A. Street, Gatun, C. Z.
6.—Lieut. W. J. Strieby, 34 Simpson Road, Ardmore, Pa.
7.—Lieut. T. W. Swartz, 53 D. Infantry, Chattanooga, Tenn.
8.—A. S. Touche, 72 West Adams Street, Chicago, Ill.
9.—R. M. Umberger, 504 West King Street, Lancaster, Pa.

PERSONAL

R. E. UPTEGRAFF has discontinued his services with the Adams-Bagnall Electric Co. of Cleveland, Ohio, and will again take up his work in Pittsburgh with the firm of Rutherfoord & Uptegraff, Consulting Electrical Engineers.

GEORGE M. OGLE, formerly Chief Electrical Engineer of the United States Shipping Board, Emergency Fleet Corporation, is now a member of the Engineering Organization in charge of the Electrical Contracting and Consulting Engineering Department of the Vulcan Iron Works, Inc., Jersey City, N. J.

WALTER J. SEELEY, recently appointed to an Instructorship in Electrical Engineering at the University of Pennsylvania, is a graduate of the Polytechnic Institute of Brooklyn, in the class of 1917. For two years following his graduation, Mr. Seeley was engaged in research and development work on submarine detection as an Ensign in the Navy, at New London, Conn., and at Plymouth, England.

C. H. ELSOM, formerly Secretary of the West Va. Engineering Co., Charlotte, West Va., announces that the Mullens Light & Power Co., Mullens, West Va., has recently been purchased and a new company, the Union Power Co., incorporated, of which he is President. Extensive improvements are contemplated among which is a thoroughly modern street lighting system for the city. The main offices are located in Charleston, West Va.

RICH D. WHITNEY, Associate Professor of Electrical Engineering, Syracuse University, and formerly Consulting Engineer of the Bureau of Water, City of Syracuse, has resigned from these positions to accept a position with the H. H. Franklin Manufacturing Company of Syracuse, where he is to be attached to the office of the Factory Manager on Special Assignments.

He left the employ of the city March first, and will leave the University at the close of the present college year.

Frank H. Bernhard, formerly managing editor of *Electrical Review*, has resigned this position to become editor of the E. M. F. Electrical Year Book. Mr. Bernhard, a graduate of Armour Institute of Technology, had some practical engineering experience and several years experience in teaching Electrical Engineering prior to his work for twelve and one-half years on the editorial staff of *Western Electrician*, later of *Electrical Review and Western Electrician*, and of *Electrical Review*. His new business address is 1018 South Wabash Avenue, Chicago.

George E. A. Fairley, for five years Assistant Chief of the Electrical Commission of the City of Baltimore, Md., has received a promotion to the grade of Lieut. Colonel, Reserve Corps of Engineers, U. S. A. Colonel Fairley served fifteen months in France, in command of a Battalion of Engineer troops, and for six months was Electrical Engineer Officer in charge on Construction, in the Intermediate Section, west, and the City of Paris District, with headquarters at Gievres, Loir et Cher. This district contained the large camps of LeMans, St. Aignan, Gievres, Romorantin, Mehun, Tours, Montierchaume, and Issoudoun.

H. R. West, recently appointed Instructor in the Electrical Engineering Department at the University of Pennsylvania, is a graduate of the University of South Dakota with the degree of M. A. He was a fellow in physics at the University of Michigan in the year 1916-1917, after which he was employed in the transmission engineering department of the Bell Telephone Company of Pennsylvania. During the war he served in the operation and maintenance department of the Hog Island Shipyard, and later in submarine detection work as an Ensign in the Navy, being detailed to the Naval Experimental Station at New London, Conn.

Chas. D. Fawcett, recently appointed Assistant Professor of Electrical Engineering at the University of Pennsylvania, is a graduate of the University of Colorado, and served as instructor at that institution for one year. For two years he worked in the testing department of the General Electric Company, and for several years served as Instructor at the University of Pennsylvania. In 1916 he was appointed Assistant Secretary of the Illuminating Engineering Society with headquarters in New York. During the war, he served as illuminating engineer for Monks and Johnson, and subsequently was the authorized representative of the Emergency Fleet Corporation in charge of the construction and operation of the Ship Steel Fabricating Plants at Pottstown and Leetsdale, Pa.

OBITUARY

Albert Percy Chapman died on March 18, 1920, following an illness of eight days of double pneumonia. Mr. Chapman was born in Springfield, Mass., February 5, 1883, and was a graduate of the Springfield High School and Worcester Polytechnic Institute. In 1914 he went to Ludlow, Mass., to take charge of electrical work for the Ludlow Manufacturing Associates, and became Superintendent of power and repairs in 1917, which office he held at the time of his death. He joined the Institute as Associate in 1906, and became a Member in 1917.

Leslie H. Harris, late Professor of Electrical Engineering at the University of Pittsburgh, died February 21, 1920. Prof. Harris was born in Bradford, Pa., October 23, 1883. In 1907 he was graduated in Electrical Engineering from Purdue University, following which he had a year's experience with the Westinghouse Elec. & Mfg. Co. From then until the time of his death he was in the Electrical Engineering Department of the University of Pittsburgh, except for the period of war, during which he was in service as Major, Q. M. C., Newport News, Va. Prof. Harris became an Associate of the A. I. E. E. in 1911, and a Member in 1912.

R. L. Cadwell, late Superintendent of Construction for the Department of Development of the Georgia Railway & Power Company, died at his home near Tallulah Falls, Ga., February 16, 1920. Born in Arizona in 1884, Mr. Cadwell received his education and early technical experience in the West. He first became associated with the Georgia Railway & Power Company in 1911 as Superintendent of Construction for the original Tallulah Falls Development under Mr. Chas. G. Adsit, then Chief Resident Engineer, having been associated with Mr. Adsit in several similar undertakings out west and in Mexico prior to his connection with this company. After the completion of the Tallulah Falls Development, Mr. Cadwell returned to the West to identify himself with some mining and copper smelting projects in Arizona, but severed his connections with these interests in the early part of 1918 to accept the position he held at the time of his death. He was a Construction man of unusual ability and wide experience, and his associates feel that his death leaves a vacancy which it will be difficult to fill. He died as a result of Pneumonia, which set in after an attack of Influenza.

Henry Smith Carhart, formerly a member of the Institute, and a recognized authority in electrical science, died suddenly, from the effects of cerebral hemorrhage, at his home in Pasadena, California, February 12, 1920. Dr. Carhart was born at Coeymans, N. Y., March 27, 1844, and was graduated from Wesleyan University in 1869. He studied at Yale 1871-2, Harvard 1876, and University of Berlin 1881-2. Wesleyan University conferred on him the degree of LL. D. in 1893. From 1872 to 1886 he was professor of physics and chemistry at Northwestern University, after which he was professor of physics at the University of Michigan until 1909, and since that date emeritus professor with the same institution. The year 1881 in Berlin was devoted to research work in the laboratory of Professor von Helmholtz, which was the beginning of investigations on voltaic cells, later developed into the production of a standard cell, involving work at the Bureau of Standards in 1910. He had been largely instrumental in establishing this Bureau through the medium of his paper presented at a meeting of the Institute in 1900 on "The Imperial Physico-Technical Institution in Charlottenburg." Dr. Carhart also contributed other papers to the Institute and many articles to technical periodicals, and was the author of various text books. He was a member of national and international committees, and served as delegate at scientific conferences. Notwithstanding his advanced age he maintained his interest in scientific work in recent years, by his intimate relations with the California Institute of Technology, formerly Throop, at Pasadena, Cal., where his appointment as research associate in physics was a great stimulus to that institution.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES FROM FEB. 1-28, 1920

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

AMERICAN GAS WORKS PRACTISE.

Standard Practical Methods in Gas Fitting, Distribution and Works Management. By George Wherle. N. Y., Progressive Age Publishing Co., 1919. 741 pp., illus., tables, 8 x 6 in., cloth, $4.00.

This work is intended as a general reference book on gas works practise in this country, with special emphasis on gas fitting practise. Approximately, one half of the book is given to the latter topic, and the methods used in street and house distribution, standards adopted, etc., are fully described.

APPLIED MOTION STUDY.

A Collection of Papers on the Efficient Method to Industrial Preparedness. By Frank B. Gilbreth and L. M. Gilbreth, N. Y., The Macmillan Co., 1919. 220 pp., plates, 1 chart, 8 x 5 in., cloth, $1.50.

This collection describes the application of motion study in various fields of activity and the methods by which it is applied. It also gives the results obtained in various cases and suggests the fields in which it may be used with benefit.

ENGINEERING EDUCATION.

Essays for English selected and edited by Ray Palmer Baker. First edition, N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1919. 185 pp., 8 x 5 in., cloth, $1.25.

CONTENTS: The origins of engineering education. The types of engineering education. The bases of engineering education.

Under these headings the Professor of English in the Rensselaer Polytechnic Institute has grouped fourteen essays, written by prominent American and English engineers during the past decade, which deal with various aspects of engineering education. The book is intended for use in elementary courses in exposition in schools of engineering.

CHILTON AUTOMOBILE DIRECTORY, January 1920.

Published quarterly by the Chilton Co., Phila. 1000 pp., 10 x 6 in., cloth, $5.00.

This quarterly directory of the automobile industry contains a classified list of the American manufacturers of passenger and commercial motor-cars, automobile equipment, parts and machinery for their manufacture. The arrangement is alphabetic and the classification is quite detailed.

In addition, the book contains a directory of automobile trade associations, a table of the serial numbers of American motor cars, the standards of the Society of Automotive Engineers and various engineering tables.

ENGINEERING MACHINE TOOLS AND PROCESSES.

A Text-Book for Engineers, Apprentices, and Students in Technical Institutes, Trade Schools and Continuation Classes. By Arthur G. Robson. Lond. & N. Y., Longmans, Green & Co., 1919. 307 pp., illus., tables, 9 x 6 in., cloth, $4.00.

This work presents a course in the systematic study of machine work and machine tools which is practical rather than theoretical in character. The methods and machines described are those used in British shops and the volume is intended for use in that country.

FATIGUE STUDY.

The Elimination of Humanity's Greatest Unnecessary Waste, a First Step in Motion Study. By Frank B. Gilbreth and Lillian M. Gilbreth. N. Y., The Macmillan Co., 1919. 175 pp., plates, 8 x 5 in., cloth, $1.50.

This book is a study of fatigue in workmen and its prevention. It aims to determine what fatigue results from various types of work and how unnecessary fatigue may be eliminated and necessary fatigue reduced to a minimum. Numerous appliances and methods are described.

HIGHWAY INSPECTOR'S HANDBOOK.

By Prevost Hubbard. First edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1919. 372 pp., 55 illus., diagrams, tables, 7 x 4 in., flexible cloth, $2.50.

The author has endeavored to present most of the important details of highway construction and maintenance, as briefly as possible, in such form as to be quickly available to the inspector, who wishes to be told what to do rather than what others have done under similar circumstances. Considerable explanatory matter has been included and diagrams have been used freely to present data in convenient form for field use. The volume is of convenient size for the pocket.

INORGANIC CHEMICAL SYNONYMS and Other Useful Chemical Data.

By Elton R. Darling. N. Y., D. Van Nostrand Co., 1919 100 pp., 7 x 4 in., cloth, $1.00.

The author has collected the various synonyms that have been used in scientific and trade literature to designate the chemicals in common use and has arranged them so that the substance in question can be accurately identified.

THE LABOR MARKET.

By Don D. Lescohier. N. Y., The Macmillan Co., 1919. 338 pp., 9 charts, 8 x 5 in., cloth, $2.25.

This work is intended for general readers. employers, legislators, employment officials, college teachers and students of the employment and labor problem. The factors of supply and demand, labor market machinery and special employment problems are discussed. The author advocates national control of the problem of employment. An extensive bibliography is included.

MANUFACTURE AND USES OF ALLOY STEELS.

By Henry D. Hibbard. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1919. 14 + 96 pp., 9 x 6 in., cloth, $1.25. (Wiley Engineering Series).

In this monograph, the author has tried to give briefly information of present value relating to the manufacture and uses of the various commercial alloy steels, with the hope of stimulating

the demand for them and extending their practical use. The steels considered are tungsten, chromium, manganese, nickel, silicon, nickel-chromium, chromium-vanadium and high speed tool steels. Bibliographies are given for each.

MUNICIPAL ENGINEERING PRACTISE.

By A. Prescott Folwell. First edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1916. 422 pp., illus., 1 plate, tables, 1 map, 9 x 6 in., cloth, $3.50.

The author of this volume has tried to provide a text-book treating all those matters which enter into the work of a city engineer, with the exception of sewerage, water supply and street paving. City plans, street details, bridges and waterways, city surveying, street lights, signs and numbers, street cleaning and sprinkling, waste disposal, markets, comfort stations, baths, parks, cemeteries and shade trees are discussed at greater or less length.

PARKS AND PARK ENGINEERING.

By William T. Lyle. First edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1916. 130 pp., illus., plates, 1 map, 9 x 6 in., cloth, $1.25.

CONTENTS: Desirability and Acquisition of Parks; Lands and Surveys; Design; Labor and Contracts; Construction.

This book is prepared for the benefit of inexperienced engineers, but will also, the author hopes, be useful to members of newly formed park associations and commissions.

TECHNICAL METHODS OF ORE ANALYSIS.

By Albert H. Low. Eighth edition N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1919. 388 pp., 21 illus., tables, 9 x 6 in., cloth, $3.25.

This manual is intended primarily for the technical chemist, for whom it provides a collection of tested short technical methods adapted to the cases most likely to be met in practise, described with minute detail. The present edition has been thoroughly revised and a number of new methods have been added.

EFFICIENT BOILER MANAGEMENT.

With notes on the operation of Reheating Furnaces. By Chas. F. Wade. Lond. & N. Y., Longmans, Green & Co. 1919. 14 + 266 pp., illus., tables, cloth, 9 x 6 in., $4.50.

The author of this work endeavors to explain, in their prope sequence, the elementary scientific principles underlying the various subjects combined in boiler management and the systematic practical application of these principles to obtain the greatest efficiency. The book is intended to fill the gap between the treatises upon the chemistry of combustion, etc., in which practical applications are omitted, and the practical text-books on boiler plants, which give little attention to the fundamental principles governing their operation.

MODERN ROADS.

By H. Percy Boulnois. Lond., Edward Arnold, 1919. 302 pp. 13 plates, figures, charts, tables, 8 x 5 in., cloth, $5.75.

This book is intended as a comprehensive survey of the present status of road construction and maintenance in Great Britain. Water-bound macadam roads, tarred, concrete and bituminous roads and pavements are included, together with chapters on bituminous carpets, waves and corrugations, and slippery streets.

PROSPECTING FOR OIL AND GAS.

By L. S. Panyity. 1st edit. N. Y., John Wiley & Sons, Inc., 1920. 249 pp., 128 fig., 28 tables, 8 x 5 in., cloth. $3.25.

This work is written for practical oil men and the general public interested in oil investments. It is intended to provide an account of the tools and methods used by scientific prospectors for oil and gas which will enable those without especial knowledge of geology to realize what may be expected of the geologist, to analyze a geological report and to pass judgment upon its merits. The book is based upon a study of the literature and the practical experience of the author, who is a member of the American Institute of Mining and Metallurgical Engineers.

TIME STUDIES FOR RATE SETTING.

By Dwight V. Merrick, with a foreword by Carl G. Barth. N. Y., The Engineering Magazine Company, 1919. 366 pp., 137 fig., 9 x 6 in., leather.

The author of this work presents in amplified form the principles covering time study for rate setting, describes various mechanisms that have been found helpful in making and using such studies and presents some details of practise. An example of the application of time studies to a line of machine tools is included, together with detailed times for a number of other kinds of work.

PRINTING TRADES BLUE BOOK.

National Edition, 1920. Chicago, edited and published by A. F. Lewis & Co., 287 pp., 8 x 6 in., cloth, $ . .

This directory contains the names and addresses of manufacturers of printers' and bookbinders' supplies and equipment arranged by firm names and lines. It is intended for makers and users of printed matter.

SAFETY FUNDAMENTALS.

Lectures given by Safety Institute of America (Maintaining the American Museum of Safety). N. Y., Safety Institute of America, 1920. 228 pp., Illus., plates, 8 x 5 in., cloth, $2.00.

CONTENTS: The body which gets hurt. The injured body and its treatment. (a) Protective clothing for man. (b) Suitable work garments for women in industry. Safe heads and good eyes. Guarding machinery. Arrangement of machinery and working places. Heating and ventilation. Illumination. Nature's forces for and against workmen. Safety education and shop organization.

These lectures were delivered during 1919 before an audience of factory inspectors employed by the City of New York, the states of New York and New Jersey, and insurance companies in and near New York. They are intended to enlarge the knowledge and increase the experience of inspectors with respect to the various fundamentals that affect the mind and body of the workman.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Boston.—February 24, 1920, Harvard Union, Cambridge, Mass. Informal dinner followed by a talk by Professor George F. Swain on "A National Department of Public Works." This was a joint meeting of The Boston Society of Civil Engineers, The Boston Sections of the A. S. M. E. and A. I. E. E. Attendance 45.

March 2, 1920, M. I. T. Dinner in the Grill Room at the Walker Memorial, M. I. T., followed by a talk by Dr. E. B. Rosa on "The Work of the Bureau of Standards During the War and After." Attendance 70.

Denver.—February 21, 1920, Kenmark Hotel. Business meeting, followed by a talk by Mr. Wilson A. Carter, who gave a very able digest on the Engineering License Laws of the United States and the model laws submitted for consideration to the national Engineering Council by its committee. Very beneficial and instructive discussion was had on this subject, participated in by a representative from the Engineer's Examining Board of the State, Mr. Hosea, and by the State Attorney General, Mr. Keys. Attendance 26.

Indianapolis-Lafayette.—February 20, 1920. Subject: "Present Day Problems in the Electric Railway Field." Speaker: Professor D. D. Ewing, of the Department of Electrical Engineering, Purdue University. The address was followed by a three-reel motion picture showing the development of transportation facilities from the earliest period in American history to the so-called "King of the Rails," the mammoth electric locomotive in use on the Chicago, Milwaukee & St. Paul, Great Northern lines and others whose tracks cross

the Rocky Mountains. In connection with the present day conditions of electric railways, Professor Ewing declared that the question was largely one of lowering operating expenses and that much was being accomplished along that line in smaller cities by the use of the one-man car. Attendance 60.

Lynn.—February 18, 1920, G. E. Hall, W. Lynn. Subject: "Electric Propulsion of Ships." Speaker Mr. Eskil Berg, of the Turbine Engineering Department, G. E. Co., Schenectady, N. Y. Mr. Berg illustrated the lecture by a large number of lantern slides as well as a moving picture film showing the propelling apparatus of the U. S. S. New Mexico. Attendance 250.

Madison.—February 24, 1920, Engineering Bldg., Univ. of Wis. Subject: "Light, A New Call to the Engineer." Speaker: Mr. E. A. Anderson, of Nela Park. Mr. Anderson gave a very interesting talk on the increased efficiency due to good lighting and showed good lighting was a paying proposition. The effect of various reflectors was discussed, and the standard R. L. M. reflector was shown. During the talk a series of slides were used showing the effect poor and good lighting has on making a factory a fit place to work in.

Philadelphia.—March 8, 1920, The Engineers Club. Subject: "Operating Performance of Insulators on a 45,000 volt System." Speaker: Mr. H. B. Vincent, of Day & Zimmerman. A discussion by representatives of operating utilities followed the meeting. Attendance 74.

Pittsfield.—February 5, 1920, Park Club. Subject: "Solar Physics." Speaker: Dr. H. T. Stetson, Cambridge, Mass. Attendance 50.

February 19, 1920, Park Club. Subject: "The Thunder Storm." Speaker: Professor William J. Humphrey, Weather Bureau, Washington, D. C. Attendance 125.

March 4, 1920, Park Club. Subject: "Ten Years in Industrial Lighting." Speaker: Professor C. L. Clewell, University of Pennsylvania. Attendance 125.

Rochester.—February 27, 1920. Subject: "Manufacture of Aluminum." Speaker: Dr. Earl Blough, Head of Research Dept., Aluminum Company of America. Attendance 37.

San Francisco.—February 26, 1920. Subject: "Automatic Railway Sub-Stations." Speaker: Mr. W. P. L'Hommedieu. The talk was illustrated with lantern slides, showing typical apparatus and also diagrams which explained the functioning of the various relays, etc. Attendance 60.

Schenectady.—February 20, 1920, Edison Club Hall. Subject: "The Last Stand of the Reciprocating Steam Engine." Speaker: Mr. A. H. Armstrong, G. E. Co. Mr. Armstrong first showed a number of slides giving data in connection with the operation of railways in the United States in the year 1918. These tables gave the total ton-mile movement, the relation between ton-miles and kw. hours as shown by the various installations from which data has been compiled. He proceeded to point out the total saving in coal both by electrification of certain zones as well as by electrification of the complete systems of the country. Data was presented showing the relative maintenance costs of the different types of electrical equipments now in use in this country and abroad. A comparison was made between these costs and those applying to the steam equipment now in use by various railways. It was pointed out that one of the essential differences in maintenance between steam and electrical equipment is due to the high standby losses of all steam equipment as well as the great amount of time required for overhauling and repairs. Attendance 230.

March 5, 1920, Edison Club Hall. Subject: "Flywheel Effect for Synchronous Motors Connected to Reciprocating Compressors." Speaker: Mr. R. E. Doherty, G. E. Co. Mr. Doherty outlines briefly the history of the application of synchronous motors to various types of mechanical loads. By means of a diagram the effect of a variable force and a constant force on a given load were shown. Starting with a simple case there was shown a method of determining the average force, and from this determination were obtained successively the values of velocity and displacement. After outlining the method a specific problem was taken and the method of calculating the different forces involved in the reciprocating unit, starting with the crank effort diagram. The method of analyzing this crank effort by a curve was shown and its use in the design of the complete unit shown. By further illustration it was shown that an extreme condition of hunting could be improved both by the addition and removal of flywheel effect. However, this same illustration proved that all of the conditions must be taken into consideration in order to obtain the proper flywheel effect for successful operation. Attendance 90.

Seattle.—February 17, 1920, Artic Club Assembly. Business meeting followed by a talk on "Electricity in Pierce County Coal Mines" by Mr. E. J. Barry, of Tacoma. The general problems involved in the installation and operation of electrical equipment in and around a coal mine were discussed and the installation of an armored cable in the Wilkenson Mine was described in detail. Attendance 45.

Toronto.—February 20, 1920, Engineers' Club. Subject: "Ice Ages and their Causes." Speaker: Dr. A. P. Coleman. The speaker described various theories as to the causes of the several ice ages, and by means of a considerable number of lantern slides showed the evidence of the Ice Ages that is available at the present day. Attendance 54.

Washington.—March 9, 1920, Cosmos Club. Business meeting, followed by an illustrated talk on "Electrolysis" by Mr. E. R. Shepard, of the Bureau of Standards. Attendance 103.

PAST BRANCH MEETINGS

Bucknell University.—March 8, 1920, Chemical Laboratory. An illustrated lecture was given by Mr. G. A. Island, of the Bethlehem Steel Co., on "The Use of Electricity in the Manufacture of Steel." Slides were shown of the different departments with generators, motors and switchboards. Attendance 51.

University of California.—February 11, 1920, Mechanics Building. Subject: "North Fork Power Plant." Speaker: Mr. C. S. King. Attendance 45.

Carnegie Institute of Technology.—February 26, 1920, Machinery Hall. Subject: "Electricity, the Servant of Man in the Home, in the Industries, in Transportation and in Ship Propulsion. Speaker: Mr. M. C. Turpin, W. E. & M. Co. The address was illustrated with about 75 lantern slides showing applications of electricity in many different industries. A number of noteworthy points were discussed and illustrated, among them the latest Turbo-Alternator of 70,000 kv-a. capacity, the Cottrell System of smoke precipitation and electrical ship propulsion. Attendance 100.

Clarkson College of Technology.—March 4, 1920. Social meeting, featuring six reels of films. Attendance 104.

Clemson Agricultural College.—March 2, 1920, E. E. Lecture Room. Subject: "Electric Power Systems of the Southern Appalachian Watershed." Discussion by Messrs. C. L. Shuler, J. W. Allison, A. H. Dula. Also "Life of Franklin" by S. N. Mace, and "Current Events" by A. R. Eppes. Attendance 56.

University of Kentucky.—February 23, 1920, Mechanical Hall. Subjects: "Series Systems for Street Lighting Distribution" (Jan. '20 Journal) C. M. Hargraves; "Starting Conditions of Synchronous Machines" (Jan. '20 Journal) C. W. Gordon; "Multiple System for Street Lighting Distribution" (Jan. '20 Journal) J. S. Misrach; "Measurement of Projectile Velocities" (Feb. '20 Journal) C. R. McClure. Attendance 19.

Massachusetts Institute of Technology.—February 26, 1920, Paper: "Electrical Transmission of Thought and of

Motion." Author: H. S. Osborne, A. T. &. T. Co. Attendance 70.

University of Michigan.—February 19, 1920. Films from electrical concerns were shown showing progress in electrification of railroads. Attendance 55.

School of Engineering of Milwaukee.—February 20, 1920. Two interesting films "The King of the Rails" and "The Benefactor" were shown. Attendance 98.

Montana State College.—February 25, 1920, Physics Lecture Room. Illustrated lecture on "Electrical Ship Propulsion" by Mr. S. Ellefson, G. E. Co. Attendance 59.

North Carolina State College.—February 10, 1920, E. E. Class-Room. Mr. M. L. Matthews read an article from the *Electrical Experimenter* about Mr. Edison. An interesting mock trial was held. Attendance 27.

February 17, 1920, E. E. Class-Room. Business meeting. Attendance 27.

February 24, 1920, E. E. Class-Room. Subject: "Hydroelectric Development." Speaker: T. G. Young. Attendance 26.

University of Notre Dame.—February 2, 1920, Engineering Hall. Subject: "Solution of the Railway Problem" by W. J. Douglass, and "Advantages Offered by the General Electric Company" by James McNulty, of the G. E. Co. Attendance 25.

March 1, 1920, Engineering Hall. Subjects: "Benefits and Impression of the Inspection Tour" by O. E. Ruzek, and "Derivation of Cyanides and Nitrogen Compounds by the Electric Furnace Method" by J. A. Bailey. Attendance 21.

Oklahoma A. & M. College.—February 18, 1920, E. E. Lecture Room. Two papers by students were presented: "Automatic Telephony" by L. L. Coleman, and "Street Lighting" by Edward Sadlo. Attendance 19.

Syracuse University.—February 18, 1920. Subject: "The Electron Theory." Speaker: Mr. B. I. Hayford. Attendance 11.

February 23, 1920. Joint meeting of A. I. E. E. Branch and A. S. M. E. in College of Applied Science. Illustrated lecture by Dr. Cook, of the McIntosh and Seymour Corporation, on Diesel Engines. Attendance 90.

A. & M. College of Texas.—February 23, 1920, E. E. Building. Business meeting; discussion of coming Electrical Show. Attendance 78.

Washington State College.—January 16, 1920, M. A. Building. Election of officers as follows: President, N. E. Lytle; Secretary, C. Kreisher. Subject: "The Future of the Young Engineer." Speaker: Prof. J. A. Ramsey. Attendance 30.

February 27, 1920, M. A. Building. Election of Glen Langdon as President to take place of N. E. Lytle. Subject: "Engineering Research Work at Washington State College." Speaker: Mr. Dana. Attendance 30.

Yale University.—February 24, 1920, Dunham Lab. of E. E. *Afternoon meeting*—Subject: "Illumination and its Relation to the Arts, Sciences and Professions." Speaker: Mr. S. E. Doane, Pres. of Illuminating Engineering Society, and Chief Engineer, National Lamp Works of G. E. Co. Attendance 100.

Evening Meeting—Subject: "Illumination in Industry—Its Relation to Production—The Economical Results." Speaker: Mr. S. E. Doane, Attendance 60.

Drexel Institute.—February 12, 1920, D. C. E. Club Rooms. Subject: "What is the Matter with Engineering?" Speaker: Prof. Disque, head of E. E. Dept. Also general discussion on Radio Telegraphy and possible communication with Mars. Attendance 19.

Michigan Agricultural College.—January 27, 1920, R. E. Old's Hall of Engineering. Mr. R. A. Shenefield presented a paper on the construction of large turbo-alternators and Mr. A. P. Bock gave a paper on Induction Generators. Attendance 16.

February 17, 1920, R. E. Old's Hall of Engineering. Two reels of motion pictures, "Queen of the Waves," were shown. This gave the entire history of water navigation beginning with the Indian's crude paddling on a log and following up to our latest super-dreadnaught which is electrically propelled. Five hundred years progress shown in thirty minutes. The pictures were supplemented by an interesting talk by Professor M. M. Cory. Attendance 77.

March 3, 1920, Lansing Chamber of Commerce. Banquet and joint meeting with M. A. C. Branch, A. S. M. E. and M. A.C. Chemical Engineering Society, and talks by the following: General Leonard A. Wood "The Engineer in War, and Our Military Policy;" O. C. Echert "Opportunities in Municipal Engineering;" F. F. Rogers "The Highway Engineer;" C. E. Bemet "The Demands of Modern Business." Mr. G. W. Bissell, Dean of Engineering, acted as Toastmaster. Attendance 150.

University of Michigan.—March 11, 1920, Engineering Building. Short business meeting, followed by a talk on "Communication" by Mr. R. S. Parker. Attendance 45.

University of Pennsylvania.—March 1, 1920, Houston Hall. A talk was given by Mr. C. W. Plass on the need of acquaintanceship outside of the engineering field; also talks by C. C. Meyer on "The Development of the Direct Current Motor" and L. O. Tashjian on "The Development of the Induction Motor." Attendance 65.

University of Washington.—March 2, 1920, Forestry Hall. Subject: "Electric Furnaces for Steel Working." Speaker: Mr. John R. King, of the Vulcan Manufacturing Company. Attendance 29.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED MARCH 12, 1920

ADAMS, CLAUDE, H., Electrician, with Donahue & Shoebottom; res., 54 Scovill Place, Detroit, Mich.

ADELBERG, I. S., Dist. Manager, Century Electric Co., 506 Rockefeller Bldg., Cleveland, Ohio.

ADMIRE, AMZI ORAL, Experimenter, National Lamp Works, General Electric Co., Nela Park, Cleveland, Ohio.

AHEARN, WILLIAM H., Railway Engineer, with John A. Beeler, 52 Vanderbilt Ave., New York, N. Y.

ANDREWS, JOSEPH F., Telephone Engineering, American Tel. & Tel. Co., 1422 Hurt Bldg., Atlanta, Ga.

ARMSTRONG, CHARLES HENRY, Inspecting Engineer, Georgia Railway & Power Co., Gas & Electric Bldg., Atlanta, Ga.

ARMSTRONG, VERNON D., Asst. Distribution Engineer, Puget Sound Traction, Light & Power Co., 601 Electric Bldg., Seattle, Wash.

AUSTERMILLER, ELMER O., Electrical Engineer, La Belle Iron Works; res., 521 6th Ave., Steubenville, Ohio.

*BACON, MARION F., Commercial Work, Battery Charging Equipment, General Electric Co.; res., 529 W. Washington Blvd., Ft. Wayne, Ind.

BAGBY, C. C., Traffic Engineer, Mountain States Tel. & Tel. Co., 1421 Champa St., Denver, Colo.

*BARNES, SHEPARD, Sales Engineer, General Electric Co., 1100 Electric Bldg., Buffalo, N. Y.

BEACH, SAMUEL W., Office Telegraph Censor, U. S. Railroad Administration; res., 707 20th St. N. W., Washington, D.C.

BEATTIE, WILLIAM P., Engineering, The American Laundry Machinery Co., Norwood, Ohio.

*WEYL, CHARLES N., Engineer, Pioneer Suspender Co., 315 N. 12th St., Philadelphia, Pa.
WHITMORE, LEE E., Chief Test Board Man, American Tel. & Tel. Co., 301 Telephone Bldg., Nashville, Tenn.
WILDBERGER, EARNEST H., Engineering Dept., Georgia Railway & Power Co.; res., 133 East Ave., Atlanta, Ga.
WILSON, ALVIN CHESLEY, Electrical Engineer, Operating Dept., Penn. Water & Power Co., 1611 Lexington Bldg., Baltimore, Md.
WIRTH, GEORGE H., Drafting & Designing, Electrical Work, Stone & Webster, 916 Chestnut St., Philadelphia, Pa.
*WOODSON, J. CLAY, Asst. Inspector of Engineering Material, U. S. Navy, at Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
WOOLFOLK, ARTHUR R., Jr., Patent Attorney, 78 Loan & Trust Bldg., Milwaukee, Wis.
WRIGHT, CHARLES ROY, Engineer, Acme Electric Co., 627 S. Gay St., Knoxville, Tenn.
YAMAOTO, KIYOSHO, Electrical Engineer, Sumitomo Electric Wire & Cable Works, Osaka, Japan.

Total 222
*Former enrolled student.

ASSOCIATES REELECTED MARCH 12, 1920

CANADA, WILLIAM J., Electrical Engineer, Stone & Webster, 147 Milk St., Boston, Mass.
KNAPP, LELAND G., Member of Firm, Goodwin & Knapp, 324 So. La Salle St., Chicago, Ill.
SCHLUSS, K. C., Puget Sound Traction, Light & Power Co.; res., 318 North J St., Tacoma, Wash.
STANFORD, FRED CLINTON, Chief Electrician, Cleveland Cliffs Iron Co.; res., 168 Davis St., Ishpeming, Mich.
WILLS, HARRY L., Engineer & Operating Manager, Georgia Railway & Power Co., Atlanta, Ga.

MEMBERS ELECTED MARCH 12, 1920

*ARNOLD, RUSSELL B., Asst. Signal Engineer, C. & N. W. R. R.; res., 5702 Washington Blvd., Chicago, Ill
BYRD, ALFRED S., Supt. of Power Plants, Montreal Tramways Co., 78 Craig St. West, Montreal, Que.
CAUDRELIER, ETIENNE, Chief Engineer of the Compagnie Parisienne de Distribution d' Electricite; res., 11 rue de Milan, Paris, France.
*COOK, JOEL R., Chief Engineer, Domestic Electric Co., Cleveland, Ohio.
DAVENPORT, FRANK B., Asst. to Electrical Engineer, Georgia Railway & Power Co.; res., 245 E. Pine St., Atlanta, Ga.
DISQUE, ROBERT C., Prof. of Electrical Engineering, Drexel Institute, Philadelphia, Pa.
EDGCUMBE, KENELM, Major, Chairman, Everett, Edgcumbe & Co. Ltd., Collingdale Works, London, N. W. 9, England.
ERICKSON, ROBERT Wm., Chief Electrical Draftsman, Federal Shipbuilding Co., Kearny, N. J.
GOKHALE, SHANKAR L. Magnetic Engineer, General Engg., Laboratory, General Electric Co.; res., 220 Liberty St. Schenectady, N. Y.
*HOPKINS, WARREN B., Acting Electrical Engineer, Stone & Webster, 147 Milk St., Boston, Mass.
MERCIER, ERNEST F. H., Administrateur delegue d l'Union d' Electricite, 57 rue Pierre Charron, Paris, France
PRIESS, WILLIAM H., Chief Engineer, Wireless Specialty Apparatus Co., C & Fargo Streets, Boston, Mass.
ROBINSON, SAMUEL M., Commander, U. S. N., Fleet Engineer; U. S. S. New Mexico, San Francisco, Cal.
TURNER, HUBERT M., Asst. Professor of Electrical Engineering, Yale University, 10 Hillhouse Ave., New Haven, Conn.
WATTS, LEVI, Jr., Sales Engineer, Westinghouse Elec. & Mfg. Co., Boston; res., 55 Wildwood Ave., Arlington, Mass.

FELLOW ELECTED MARCH 12, 1920

NASH, GEORGE HOWARD, Chief Engineer, Western Electric Co. Ltd., Norfolk House, Embankment, London, England.

TRANSFERRED MARCH 12, 1920

To Grade of Member

BEARDSLEY, CLIFFORD R., Electrical Engineer, Fred T. Ley & Co. Inc., Springfield, Mass.
CARROLL, RANDOLPH S., Superintendent, Underground Dept., Portland Railway, Light & Power Co., Portland, Ore.
DUBSKY, FRANCIS, Electrical Engineer, Transformer Engineering Dept., General Electric Co., Pittsfield, Mass.
ELDREDGE, MARK, Engineer, Ludlow Manufacturing Associates, Calcutta, India.
FOSTER, BENJAMIN P., Electrical Engineer, E. I. Du Pont de Nemours & Co., Wilmington, Del.
HESTON, WALTER C., Industrial Power Engineer, Portland Railway, Light & Power Co., Portland, Ore.
HUNT, RAYMOND, General Manager, Tide Water Power Co., Wilmington, N. C.
LINCOLN, JAMES F., General Manager, Lincoln Electric Co., Cleveland, O.
MORTON, ROBERT B., Electrical Engineer, Toltz King & Day, St. Paul, Minn.
NAMBA, MASASHI, Professor of Electrical Engineering, Imperia University, Kioto, Japan.
SCHIPPEL, HENRY F., Research Engineer, Ames Holden McCready, Ltd., Montreal, Que.

SOLOMON, NATHAN C., Contracting Electrical Engineer, New York, N. Y.

STRAW, JESSE B., Chief Engineer, The William Gordon Corp. Philadelphia, Pa.

WISEMAN, ROBERT J., Wire and Cable Engineer, National Conduit & Cable Co., Inc., Hastings-on-Hudson, N. Y.

To Grade of Fellow

GOLDSMITH, ALFRED N., Professor in Charge of Electrical Engineering, College of the City of New York, New York, N. Y.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at a meeting held March 8, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Membership

ATKINSON, KERR, Engineer, with Roderick D. Donaldson, New York, N. Y.

CANADA, WILLIAM J., Electrical Engineer, Stone & Webster, Boston, Mass.

FAIR, RICHARD H., Outside Plant Engineer, Bell Telephone System, Northwestern Group, Omaha, Neb.

HOWLAND, RALPH B., Assistant Electrical Engineer, Dwight P. Robinson & Co. Inc., New York, N. Y.

IVES, JOHN NASH, Electrical Engineer, Lockwood, Greene & Co., Boston, Mass.

McEACHRON, KARL B., Research Assistant, Engineering Experiment Station, Purdue University, Lafayette, Ind.

REGAL, A. P., Electrical Engineer, Philadelphia Rubber Works Co., Akron, O.

SCHLUSS, KURT C., Supt. of Power & Equipment, Tacoma Ry. & Power Co., Puget Sound Electric Ry., Puget Sound Traction Lt. & Pr. Co. (Tacoma Div.), Tacoma, Wash.

STANFORD, F. C., Chief Electrician, Cleveland Cliffs Iron Co., Ishpeming, Mich.

STELZNER, W. B., Professor of Electrical Engineering, University of Arkansas, Fayetteville, Ark.

THORNTON, FRANK Jr., Chief Engineer, Westinghouse Electric Products Co., Mansfield, O.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before April 30, 1920.

Abbott, Royal W., San Francisco, Cal.
Albrecht, E. Julius, (Member), Chicago, Ill.
Appel, Henry J., New York, New York.
Aslaksen, Einer, New York, N. Y.
Baily, Ben P., Astoria, Oregon.
Balch, Cleon F., Milwaukee, Wis.
Barnes, Edwin H., Philadelphia, Pa.
Batt, Charles G., Bingham Canyon, Utah.
Beacock, Victor A., Toronto, Ont.
Beatty, Elwood C., (Member), Ampere, N. J.
Beckett, William, (Member), Atlanta, Ga.
Beechinor, Herbert M., New York, N. Y.
Bemis, Edwin W., Worcester, Mass.
Benedict, Roy P., Chicopee, Massachusetts.
Birkinbine, Olaf W., Philadelphia, Pa.
Bischoff, Louis G., Chicago, Ill.
Bissett, John W., New York, N. Y.
Bloch, S., Schenectady, N. Y
Bohmann, Robert B., Milwaukee, Wis.
Bolen, Charles A., Greensburg, Pa.
Bolton, Robert A., Kingston, Ontario
Bordeaux, Ephriam P., New York, N. Y.
Boss, Earle, B., W. Lynn, Massachusetts.
Boutwell, Willard S., Seattle, Washington.
Bowler, William E., Worcester, Mass.
Bowman, Edward C., (Member), New York, N. Y.
Bridges, J. Earle, Jackson, Mich.
Brodsky, Vladimir P., E. Pittsburgh, Pa.
Brown, Harrison G., Portsmouth, New Hampshire.
Brown, Richard, Worcester, Mass.
Bugbee, Ralph L., Boston, Mass.
Burger, Edward J., (Member), Lorain, Ohio
Burman, Charles F., Milwaukee, Wisconsin.
Butler, W. H., Philadelphia, Pa.
Buxton, Vernon R., Boston, Mass.
Calligheris, John S., E. Pittsburgh, Pa.
Carpe, Allen, New York, N. Y
Church, Robert A., New York, New York.
Cigrange, Joseph, Baltimore, Massachusetts.
Clapp, Robert H., New York, New York.
Clark, John A., (Member), Pittsburgh, Pa.
Cox, Robert W. S., Boston, Mass.
Cross, Raymond J., Hoboken, N. J.
Creim, Benjamin W., Los Angeles, Cal.
Daunt, Charles A., S. Boston, Massachusetts.
Davis, Carlos, Glens Falls, N. Y.
Debman, Eugene E., New York, New York
Dee, Thomas C., Ames, Iowa
d'Humy, Fernand E., New York, New York.
Denny, Robert C., Fresno, Cal.
Dewey, Stuart J., Cincinnati, Ohio
Dodge, Harry A., (Member), New York, N. Y.
Duff, John E., Chicago, Illinois.
Dupre, Valentine H., Chicago, Ill.
Eaton, Frederick W., Akron, Ohio
Edmonds, Montrose, Baltimore, Md.
Elliott, James P., (Member), Milwaukee, Wis.
Elstun, William P., New York, New York
Emerson, Cherry L., (Member), Atlanta, Ga.
Fay, Carl J., Mansfield, Ohio.
Ferguson, Alan H., Chicago, Ill.
Fisher, Merdaunt J. M., E. Pittsburgh, Pa.
Flaherty, Leonard T., Stellarton, N. S.
Ford, James E., Somerville, Mass.
Foss, Carl E., Chicago, Ill.
Fowler, Herman M., Seattle, Wash.
French, Ralph W., E. Pittsburgh, Pa.
Frick, Clifford H., Hauto, Pa.
Frisbie, Howard L., (Member), Clarkdale, Ariz.
Fry, Howard M., Bethlehem, Pa.
Fryburg, Warren, New York, N. Y.
Fuller, Carl T., (Member), Harrison, N. J.
Fyke, J. Lowell, (Member), W. Allis, Wis.
Gatter, L. Stewart, (Member), New York, N. Y.
Geder, John J., Milwaukee, Wis.
Giesselberg, George H., New York, N. Y.
Gilson, Wesley J., (Member), Calumet, Mich.
Gross, Frank W., Ft. Sam Houston, Texas
Grunfield, Maurice, New York, N. Y.
Grunsky, Clotilde, San Francisco, Cal.
Hall, Theodore, (Member), Brooklyn, N. Y.
Hardy, George M., (Member), Worcester, Mass.
Harris, Leonard F., New York, N. Y.
Harvey, Lloyd B., Portsmouth, N. H.
Hatz, Earl W., Milwaukee, Wis.
Hecht, J. Bernard, St. Paul, Minn.
Heckman, Chester L., Worcester, Mass.
Heffner, Roy E., Ithaca, N. Y.

11276 Snider, W. Herbert, University of Wisconsin
11277 Kauffman, Paul E., Y. M. C. A. School
11278 Satori, Roy H., University of Minnesota
11279 Freehauf, Harvey G., University of Minnesota
11280 Overstreet, Frank A., University of New Mexico
11281 Forrest, Henry C., University of Virginia
Total 73

OFFICERS of A. I. E. E. 1919-1920

PRESIDENT.

(Term Expires July 31, 1920)
CALVERT TOWNLEY

JUNIOR PAST-PRESIDENTS.

(Term expires July 31, 1920) E. W. RICE, JR.
(Term expires July 31, 1921) COMFORT A. ADAMS

VICE-PRESIDENTS.

(Terms expire July 31, 1920)
A. M. SCHOEN, L. R. JORGENSEN
C. E. SKINNER, N. A. CARLE
JOHN B. FISKEN, WILLS MACLACHLAN

MANAGERS.

(Terms expire July 31, 1920) CHARLES S. RUFFNER, CHARLES ROBBINS, E. H. MARTINDALE
(Terms Expire July 31, 1921) WALTER A. HALL, WILLIAM A. DEL MAR, WILFRED SYKES

(Terms Expire July 31, 1922) WALTER I. SLICHTER, G. FACCIOLI, FRANK D. NEWBURY
(Terms Expire July 31, 1923) L. E. IMLAY, F. F. FOWLE, L. F. MOREHOUSE

TREASURER **SECRETARY**
(Term expires July 31, 1920)
GEORGE A. HAMILTON F. L. HUTCHINSON

HONORARY SECRETARY
RALPH W. POPE

DIRECTOR OF THE LIBRARY
HARRISON W. CRAVER

GENERAL COUNSEL
PARKER and AARON,
52 Broadway, New York.

PAST PRESIDENTS—1884-1919

*NORVIN GREEN, 1884-5-6.
*FRANKLIN L. POPE, 1886-7.
T. COMMERFORD MARTIN, 1887-8.
EDWARD WESTON, 1888-9.
ELIHU THOMSON, 1889-90.
*WILLIAM A. ANTHONY, 1890-91.
ALEXANDER GRAHAM BELL, 1891-2.
FRANK JULIAN SPRAGUE, 1892-3.
*EDWIN J. HOUSTON, 1893-4-5.
*LOUIS DUNCAN, 1895-6-7.
FRANCIS BACON CROCKER, 1897-8.
A. E. KENNELLY, 1898-1900.
CARL HERING, 1900-1.
CHARLES P. STEINMETZ, 1901-2.
CHARLES F. SCOTT, 1902-3.
BION J. ARNOLD, 1903-4.
JOHN W. LIEB, 1904-5.
SCHUYLER SKAATS WHEELER, 1905-6.
SAMUEL SHELDON, 1906-7.
*HENRY G. STOTT, 1907-8.
LOUIS A. FERGUSON, 1908-9.
LEWIS B. STILLWELL, 1909-10.
DUGALD C. JACKSON, 1910-11.
GANO DUNN, 1911-12.
RALPH D. MERSHON, 1912-13.
C. O. MAILLOUX, 1913-14.
PAUL M. LINCOLN, 1914-15.
JOHN J. CARTY, 1915-16.
H. W. BUCK, 1916-17.
E. W. RICE, JR., 1917-18.
COMFORT A. ADAMS, 1918-19.

***Deceased.**

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

Calvert Townley, Chairman, 165 Broadway, New York.
N. A. Carle, W. A. Hall, George A. Hamilton,
L. F. Morehouse, W. I. Slichter, C. E. Skinner.

FINANCE COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Hall, L. F. Morehouse.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
L. W. Chubb, E. E. F. Creighton, John H. Finney,
L. R. Jorgensen.
Chairman of Committee on Technical Activities, the chairmen of all technical committees, and the chairmen of all Sections.

PUBLICATION COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
N. A. Carle, Wm. A. Del Mar, F. L. Hutchinson
Harold Pender

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
J. H. Morecroft, H. N. Latey, Wm. S. Murray,
H. H. Norris, E. M. Sawtelle, Clayton H. Sharp,
Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, General Electric Co., West Lynn, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd,
and the chairmen of all Institute Sections *ex-officio.*

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker,
Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose,
G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb,
A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins,
D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 20 Nassau St., New York.
F. B. Crocker, Vice-President,
James Burke, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.
Comfort A. Adams, H. W. Fisher, David B. Rushmore,
P. G. Agnew, H. M. Hobart, Charles F. Scott,
B. A. Behrend, Dugald C. Jackson, Clayton H. Sharp,
John J. Carty, B. G. Lamme, C. E. Skinner,
L. W. Chubb, W. S. Moody, S. W. Stratton,
W. A. Del Mar, A. H. Moore, Elihu Thomson,
Gano Dunn, Charles Robbins, R. B. Williamson.
Walter C. Fish, E. B. Rosa,

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
J. C. Forsyth, H. B. Gear, H. O. Lacount,
Johnston Livingston, M. G. Lloyd, R. W. E. Moore,
Henry N. Muller, H. R. Sargent, G. A. Sawin,
A. M. Schoen, George F. Sever, H. S. Warren.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, L. B. Stillwell,
Schuyler Skaats Wheeler.

BOARD'S COMMITTEE ON TECHNICAL ACTIVITIES

Wilfred Sykes, Chairman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
G. Faccioli, W. I. Slichter.

STANDARDS COMMITTEE

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
E. J. Cheney, Secretary, Public Service Commission, Albany, N. Y.
P. G. Agnew, G. A. Anderegg, Frederick Bedell,
L. F. Blume, James Burke, G. A. Burnham,
P. H. Chase, H. H. Clark, F. P. Cox,
E. B. Craft, W. A. Del Mar, F. M. Farmer,
H. W. Fisher, F. C. Hanker, H. M. Hobart,
H. H. Humphrey, H. D. James, P. Junkersfeld,
A. E. Kennelly, G. L. Knight, R. W. Krass,
C. O. Mailloux, C. S. McDowell, W. L. Merrill,
Taliaferro Milton, L. F. Morehouse, F. D. Newbury,
H. S. Osborne, S. G. Rhodes, Charles Robbins,
R. F. Schuchardt, C. E. Skinner, A. B. Smith,
John B. Taylor, A. H. Timmerman, W. K. Vanderpoel.
R. B. Williamson.

EDISON MEDAL COMMITTEE

Appointed by the President for terms of five years

Term expires July 31, 1920.
Carl Hering, Chairman, Harris J. Ryan, Robert Lindsay.
Term expires July 31, 1921.
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
Term expires July 31, 1922.
Comfort A. Adams, L. A. Ferguson, S. W Stratton.
Term expires July 31, 1923.
Frederick Bedell, L. T. Robinson, Calvert Townley.
Term expires July 31, 1924.
E. D. Adams, H. H. Barnes, B. G. Lamme.

Elected by the Board of Directors from its own membership for terms of two years.

Term expires July 31, 1920.
Charles Robbins, C. E. Skinner, W. I. Slichter.
Term expires July 31, 1921.
G. Faccioli, W. A. Hall, Wilfred Sykes.

Ex-Officio

Calvert Townley, President, George A. Hamilton, Treasurer.
F. L. Hutchinson, Secretary.

SPECIAL COMMITTEE

COMMITTEE ON DEVELOPMENT

Charles F. Scott, Chairman, Sheffield Scientific School, Yale University, New Haven, Conn.

F. F. Brand, Pittsfield, Mass.
J. C. Clark, San Francisco, Cal.
Ira M. Cushing, Boston, Mass.
W. A. Del Mar, New York, N. Y.
H. W. Eales, St. Louis, Mo.
F. R. Ewart, Toronto, Ont.
W. A. Hall, W. Lynn, Mass.
W. F. James, Philadelphia, Pa.
Leslie Killam, Milwaukee, Wis.
P. M. Lincoln, Cleveland, O.
A. S. MacDowell, Rochester, N. Y.
H. T. Plumb, Salt Lake City, Utah.
A. M. Schoen, Atlanta, Ga.
C. H. Schum, Erie, Pa.
Samuel Sheldon, Brooklyn, N. Y.
N. W. Storer, Pittsburgh, Pa.
H. L. Wallau, Cleveland, O.
J. Lloyd Wayne, Indianapolis, Ind.
H. E. Bussey, Atlanta, Ga.
Clem A. Copeland, Los Angeles, Cal.
R. H. Dalgleish, Washington, D. C.
F. G. Dustin, Minneapolis, Minn.
H. S. Evans, Boulder, Colo.
Baxter R. Grier, Gatun, C. Z.
John Harisberger, Seattle, Wash.
V. Karapetoff, Ithaca, N. Y.
J. J. Kline, Fort Wayne, Ind.
Chas. A. Lund, Spokane, Wash.
John C. Parker, Ann Arbor, Mich.
L. T. Robinson, Schenectady, N. Y.
R. F. Schuchardt, Chicago, Ill.
W. D. Scott, Portland, Ore.
G. E. Snider, Toledo, O.
L. E. Underwood, W. Lynn, Mass.
J. W. Watson, Madison, Wis.
J. B. Whitehead, Baltimore, Md.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, 644 Riverside Drive, New York.
H. V. Bozell, John B. Fisken, W. S. Gorsuch,
L. G. Ireland, A. H. Kruesi, J. F. Meyer,
S. G. Rhodes, Allard Smith, E. H. Sniffen,
P. B. Yates.

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.
C. R. Dooley, F. F. Fowle, Charles S. Howe,
C. E. Magnusson, E. B. Merriam, L. F. Morehouse,
G. H. Pfeiff, H. W. Price, R. F. Schuchardt,
W. I. Slichter, William R. Work.

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.
James Burke, Alexander Churchward, A. M. Dudley,
C. E. Eveleth, G. Faccioli, B. G. Lamme,
A. C. Lanier, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.
F. F. Ambuhl, E. R. Berry, Joseph L. Dixon,
I. R. Edmands, L. E. Imlay, F. A. Lidbury,
W. R. Whitney, J. L. Yardley.

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
P. G. Agnew, H. D. Arnold, E. F. Burton,
L. W. Chubb, J. C. Clark, C. P. Eldred,
E. P. Hyde, Chester W. Rice, C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.
P. H. Adams, E. V. Buchanan, H. W. Cope,
Wm. E. Date, James Dixon, A. M. Dudley,
R. H. Goodwillie, H. D. James, W. C. Kalb,
R. H. McLain, E. H. Martindale, A. H. Timmerman,
L. E. Underwood, H. Weichsel, R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 104 E. 32nd St., New York.
C. W. Baker, Wm. M. Bradshaw, H. B. Brooks,
F. P. Cox, F. V. Magelhaes, Charles Robbins,
Clayton H. Sharp.

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.
F. B. Crosby, F. D. Egan, Gordon Fox,
Eugene Friedlaender, E. S. Jefferies, W. C. Kennedy,
D. M. Petty, Wm. T. Snyder, Wilfred Sykes,
R. B. Williamson, Fred H. Woodhull, J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. N. Chamberlin, J. R. Cravath, Terrell Croft,
N. S. Dickinson, Bassett Jones, F. D. Newbury,
P. G. Nutting, R. C. Powell, E. B. Rosa,
W. D'A. Ryan, W. M. Skiff, G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.
R. A. Beekman, Eskil Berg, A. R. Cheyney,
Maxwell W. Day, E. G. Gallagher, H. L. Hibbard,
W. F. James, C. A. Jones, C. S. McDowell,
W. F. Meschenmoser, I. H. Osborne, G. A. Pierce, Jr.
J. B. Porter, L. B. Sinclair, H. M. Southgate,
Wilfred Sykes, W. E. Thau, A. E. Waller
F. W. Wood.

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.
R. T. Andrae, F. H. Armstrong, Graham Bright,
L. C. Ilsley, R. L. Kingsland, A. B. Kiser,
Wills Maclachlan, E. B. Woodward.

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.
J. T. Barron, A. E. Bauhan, E. T. Brandon,
H. W. Eales, W. L. R. Emmet, W. S. Gorsuch,
H. P. Liversidge, I. E. Moultrop, Frank D. Newbury,
H. S. Putnam, R. F. Schuchardt, Russell W. Stovel
H. L. Wallau. R. B. Williamson.

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.
G. E. Armstrong, P. H. Chase, W. H. Cole,
E. E. F. Creighton, H. W. Eales, F. C. Hanker,
E. M. Hewlett, F. L. Hunt, P. MacGahan,
D. A. McKenzie, A. A. Meyer, L. C. Nicholson,
N. L. Pollard, F. E. Ricketts, Charles Robbins,
T. C. Taliaferro, H. R. Woodrow.

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 253 Broadway, New York.
O. B. Blackwell R. E. Chetwood E. H. Colpitts
H. W. Drake, W. B. Kouwenhoven, L. F. Morehouse,
R. W. Osborne, W. O. Pennell, L. M. Potts,
S. A. Rhodes, A. B. Smith, D. M. Therrell,
W. H. Winter, D. E. Wiseman.

TRACTION AND TRANSPORTATION

W. S. Murray, Chairman, Room 2800, 165 Broadway, New York.
A. H. Babcock, Reinier Beeuwkes, R. H. Dalgleish,
W. G. Gordon, John Murphy, W. B. Potter,

The Corona Voltmeter and the Electric Strength of Air

A Natural Secondary Standard of Voltage

BY J. B. WHITEHEAD

Professor of Electrical Engineering, John Hopkins University

AND

T. ISSHIKI

Engineer, Shibaura Engineering Works

An improved form of the corona voltmeter is described. Precision measurements of crest values of high alternating voltage taken in the high-tension circuit are compared with the indications of the corona voltmeter.

The law of corona has been determined to a higher degree of accuracy, and a modification in the form of the law as heretofore accepted is revealed.

As based on the precision voltage measurements the corona voltmeter is proposed as a natural secondary standard of high voltages. Its advantages as a standard, and its practical operation are described.

I. Introduction

THE corona voltmeter is an instrument for measuring accurately the crest values of high alternating voltages. It makes use of the fact that corona forms on a clean round wire in air at a sharply marked definite value of voltage dependent in a simple relation on the density of the air. The range of the instrument using a single wire is extended to wide limits by enclosing the wire and varying the density of the air.

The essential elements of the instrument are a central rod or wire on which corona forms, an outer concentric cylinder forming the opposite terminal, an outer air-tight containing case in which the air pressure may be varied, and convenient means for determining accurately the first appearance of corona. The principle and method of operation, including the use of gaseous ionization and sound as corona indicators, and two earlier forms of the instrument have been described in an earlier paper.[1] An improved type of the instrument for voltages in the neighborhood of 150,000 volts is described below and shown in Figs. 9 and 10.

The principal object of this paper is to describe a series of experiments in which the values of corona forming crest voltages have been determined by precision measurements made in the high-voltage circuit. Also to show that the law followed is so definite, and the indications of the instrument so constant, that it constitutes not only an accurate measuring instrument, but also through the results of the present investigation, a natural secondary standard of high voltage possessing many advantages over others at present in use.

An important result of the work is the discovery of an interesting modification of the law of corona formation.

The various precautionary and check measurements staken to ensure the accuracy of the final readings con titute in themselves prime evidence of the accuracy of the corona as a measure of voltage, and also of its constancy and reliability in operation in the corona voltmeter. In addition some further notes on the operation of the voltmeter are given towards the end of the paper.

II. The Corona as a Standard of Voltage

Two striking properties of the high-voltage corona in air have led to the suggestion of its use for the measurement of voltage and to the development of the corona voltmeter. The first is the remarkable constancy of the value of voltage at which, under fixed conditions, the corona appears on a round wire or rod; and the second is the simplicity of the law connecting the critical or corona-forming voltage with the diameter of the rod and the condition of the surrounding gas.

The former of these properties has been noted by a number of observers and in particular by one of the present authors in the first of a series of papers on the electric strength of air,[2] and again especially in a paper on the corona voltmeter.[1] Using a clean round rod and the best type of portable voltmeter in the low-tension circuit, on repeated raising and lowering of the voltage corona appears sharply at exactly the same value throughout, that is, at a value constant to within say one-tenth or one-quarter per cent. Under more refined conditions the constancy is shown to be even closer.

The empirical law connecting the critical or corona-forming voltage gradient E in kilovolts per cm., at the surface of the wire, the radius of the wire r in centimeters, and the relative density of the gas δ, is usually stated in the form

$$E = A\,\delta\left(1 + \frac{B}{\sqrt{\delta\, r}}\right) \qquad (1)$$

A more convenient form for our present purposes is

$$E/\delta = A + \frac{B'}{\sqrt{\delta\, r}} \qquad (2)$$

To be presented at the Annual Convention of the A. I. E. E., June 29—July 2, 1920.

1. A bilbiography of all references will be found at the end of the paper.

which gives a linear relation between E/δ and $\frac{1}{\sqrt{\delta\, r}}$; obviously $B' = A\, B$.

The value of δ is given by

$$\frac{3.92\, p}{273 + t} \tag{3}$$

in which p is the pressure in centimeters of mercury and t is the temperature in degrees centigrade.

The above relatively simple relations have now been corroborated by a number of observers and with quite close agreement as to the values of A and B. The influence of the diameter of the wire on corona-forming voltage was first emphasized by H. J. Ryan,[3] who was also the first to point out the possibilities of the corona as a voltage indicator. The exact nature of this influence and the presence of the two constants A and B were first shown by one of the present authors.[4] The precise influence of the density of the air was first shown by F. W. Peek, Jr.,[5] in one of the most important contributions yet made to the knowledge of the subject. Moisture in the air has no effect on the critical intensity.[2]

The form of the above law is the same for both continuous voltages and crest values of alternating voltages. With continuous voltage, however, there are appreciable differences in the values of the constants A and B, as between positive and negative corona-forming wire, the form of the law in each case remaining the same.[6] One of the most important results of the present work is the fact that this difference between positive and negative corona is reflected in the alternating corona, and that the law as given by formulas (1) and (2) must be modified. Briefly stated, the modification consists in the use of different values of the constants A and B above and below a definite value of $\frac{1}{\sqrt{\delta\, r}}$, the form of the law, however, remaining the same in each case, as will be seen below.

It has generally been accepted that within the commercial range frequency has no influence on the corona-forming voltage. Observations with the accurate methods use in the experiments show a slight influence of frequency within the range mentioned.

Since corona formation through the constancy of its appearance and the simplicity of its law offers a ready means for the measurement of high voltage, it is important that the constants A and B be determined accurately. When this is once done, such an instrument as the corona voltmeter has a calibration dependent only on its dimensions, and so constitutes a natural secondary standard of voltage.

Nearly all determinations of alternating corona voltages have been based on observations of voltage and crest factor taken in the low-tension circuit, and computed from transformer ratios. As is well known, this method is subject to serious errors on both accounts. If therefore advantage is to be taken of the constancy of corona voltage as a standard and as a method of measurement, it is necessary that the constants A and B be determined by direct measurement in the high-voltage circuit of the crest values of corona voltage, and to a relatively high degree of accuracy in terms of accepted standards. These determinations once made over a sufficiently wide range of values of δ, corona formation, by reason of the simplicity of the relation of formula (1), and its freedom from outside influence, becomes a far more reliable standard than the sphere gap, the potential transformer, or any other standard at present proposed.

III. Precision Measurement of Corona Constants

For the determination of the values of A and B we must (1) measure accurately the crest value of alternating voltage at which corona appears, (2) be able to observe to as small a difference of voltage as possible the first appearance of corona, and (3) measure δ and provide a wide range of its values.

The crest value of voltage (1) may be determined from the average value of the charging current of an air condenser in the high-voltage circuit. This method first used by Chubb and Fortescue,[7] was modified by Whitehead and Gorton,[8] and is now further improved as described below.

For (2) the accurate observation of the first appearance of corona, two methods are used,—(a) the telephone for detecting the sound of the corona, and (b) the galvanometer for detecting the conductivity of the air caused by the corona. Both methods are used in the corona voltmeter and are described in detail in an earlier paper;[1] further observations are reported below. The visibility of corona is neither convenient nor accurate as a means of determining its first appearance.

The corona voltmeter with its air-tight outer casing provides the method (3) for the observation of δ, the relative air density, and its variation over a wide range. Pressure and temperature are read and the pressure may be adjusted to any chosen value, thus permitting setting for any value of δ.

III. 1. Measurement of Voltage

If an alternating voltage of maximum value E volts and frequency f be impressed on a condenser of capacity C, the average charging current is

$$i = 4\, f\, C\, E; \tag{4}$$

if f and C are known and i is measured E the maximum for the maximum value of charging voltage is determined. When used for the high values of voltage pertaining to corona formation, one side of the condenser is grounded and the charging current measured in the ground connection. Since the condenser must withstand the full maximum voltage and have no dielectric or other loss, the most convenient form is that of concentric cylinders with wide radial separation, and

with air as dielectric. This, however, means small capacity per unit axial length, and small total capacity if the outside dimensions are to be kept within reasonable limits. Consequently the use of this method involves the use of a large air condenser of small capacity and a determination of the value of the capacity.

Chubb and Fortescue[7] constructed a cylindrical condenser consisting of two wooden forms, each covered with sheet metal surfaces. The diameters of the two members were 60 cm. and 162.8 cm. respectively, and the outer member was provided with two flaring guard ring ends. The capacity between the inner member and the central section of the outer member was calculated as 2.65×10^{-11} farad, no attempt at measurement being made, doubtless owing to the difficulty of measuring so small a value. Chubb and Fortescue measured the charging current in the ground connection of the central section of the outer member of the condenser by means of a d'Arsonval galvanometer and a synchronous commutator connected as a shunt suppressor.

In the present experiments the same type of condenser is used, *i. e.*, the cylindrical guard ring type with voltage applied to the inside member and charging current measured in the ground connection of the central section of the outside member. The capacity, however, was measured, as described below. Further, the charging current was measured by the use of two rectifying kenotrons, thus obviating the irregularities and uncertainties of the synchronous commutator. The commutator was, however, frequently used for comparison and certain auxiliary tests.

A diagram of the principal connections is shown in Fig. 1. Voltage is applied from the transformer A to

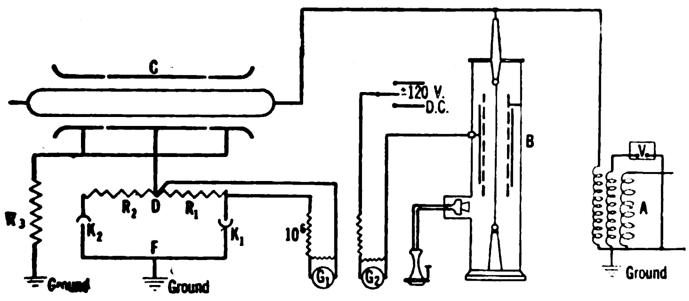

FIG. 1—PRINCIPAL CONNECTIONS

the corona voltmeter B and the air condenser C. The charging current of the central section of the latter passes to ground in alternate half waves through the resistances and kenotrons R_1, K_1, and R_2, K_2. The currents in R_1 and R_2 are therefore pulsating but unidirectional and so may be read by a continuous-current instrument in series or in shunt, as shown in Fig. 1, G_1 being a sensitive d'Arsonval galvanometer critically damped. A second galvanometer G_2 and a telephone T are used to detect the first appearance of corona on the central rod of the corona voltmeter as described below. A number of auxiliary circuits have been omitted from Fig. 1 and will be referred to in connection with the various measurements.

We will now describe in turn the methods of measuring the charging current, the frequency, and the capacity of the condenser, together with the precautions taken, the limits of accuracy, and all leading to the determination of the value of voltage present on the first appearance of corona in the corona voltmeter B.

(*a*) *Charging Current.* Balance in kenotron circuit. In formula (4) i is the average value of the charging current. In Fig. 1 all positive half waves will pass through one kenotron and all negative half waves through the other. The d'Arsonval galvanometer in shunt to the resistance R_1 will therefore receive a

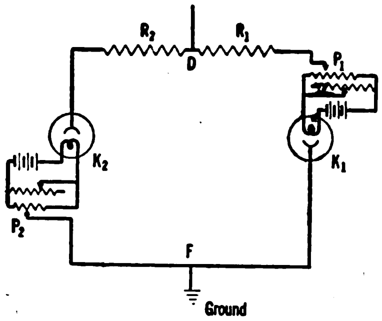

FIG. 2—KENOTRON CONTROL

tion the galvanometer will read one-half the average value of the charging current. In view of the foregoing it is of first importance that when no charging current is passing there be no continuous current flowing in the closed circuit $K_1 D K_2 F$. This condition was realized by the adjustment of the point of connection to the filament exciting circuits of the kenotrons as indicated at $P_1 P_2$ in Fig. 2. This in pulsating unidirectional current and show a deflection proportional to its average value. Obviously the combination may be calibrated directly in terms of continuous current in R_1 and in terms of such a calibra-effect interposes a small adjustable e. m. f. counter to the normal direction of conductivity, at each kenotron. If this is not done the normal leak of electrons from the filament, particularly at its negative end, results in a small current in the circuit $K_1 D K_2 F$. In making these adjustments the galvanometer G_1 was connected first in series in the circuit $K_1 D K_2 F$ and then between the points D and F, repeating with adjustments at P_1 and P_2 until both readings are simultaneously zero. After balancing the kenotron circuit, as above, it was connected into the condenser ground circuit and with alternating voltage on was further balanced for equal resistance in the two branches by adjustment for zero current in the galvanometer connected across $D F$; on removal of the alternating voltage the circuit $K_1 D K_2 F$ is still balanced. Without these adjustments a small error is possible, the galvanometer G_1 in the connection of Fig. 1 showing at times a deflection of 0.5 mm.; after

the adjustments mentioned no deflection can be detected.

(*b*) *Influence of Wave Form.* The use of the kenotrons for rectifying the charging current introduces an error if the wave form of voltage is not smooth, *i. e.*, if it has more than one maximum in each half wave. In this case there is a reversal of condenser current following every such maximum or elevation in the wave and since the kenotron passes current in only one direction, this reverse current passes through the opposite kenotron and so does not contribute to the galvanometer reading. Similarly in the next half cycle the reverse current is recorded in the galvanometer as positive. Thus due to both half waves the result is a galvanometer reading higher than that corresponding to the average charging current.

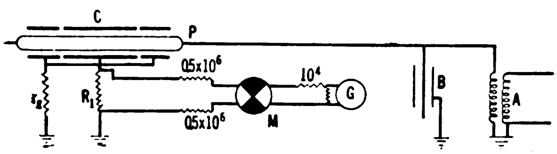

FIG. 3—MEASUREMENT OF CONDENSER CHARGING CURRENT WITH SYNCHRONOUS COMMUTATOR

The generator used in the experiments has a surface wound armature and shows a smooth wave on an oscillogram. The inserts of Figs. 4 and 5 show the voltage waves as taken from a low-tension tertiary coil on the transformer T, Fig. 1, for series and parallel connections respectively of the two primary coils. In order, however, to answer this question definitely, the wave form of the voltage at the high-tension terminals was taken by the method indicated in Fig. 3, in which

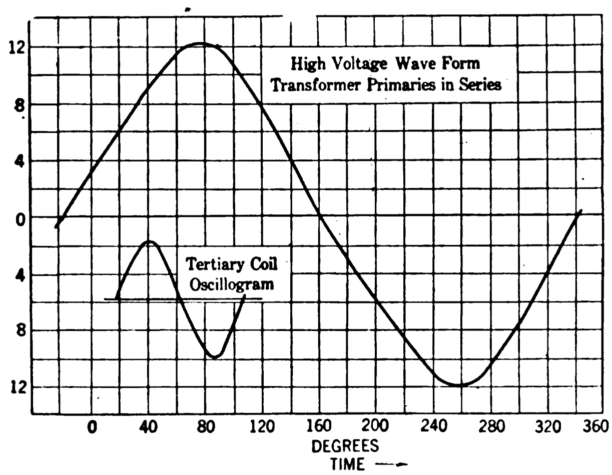

FIG. 4—HIGH-VOLTAGE WAVE FORM

M is the synchronous comutator connected as full rectifier or as half-wave suppressor. In this method first pointed out by Bedell,[9] for any position of the brushes the galvanometer reading is proportional to the average value of the charging current for any particular half-wave interval between the brushes, and this in turn is proportional to the instantaneous value of the voltage on the condenser. Figs. 4 and 5 show the wave forms so taken for series and for parallel connections respectively of the transformer primary coils, which together with Table I, giving a section from the complete sheet of readings, indicate the conditions of accuracy. The mean values of right and left readings of the galvanometer are taken in all cases in order to eliminate a slight right and left dissymmetry probably due to electrostatic disturbance, generally noticeable in the very sensitive galvanometer, in spite of most careful screening. For obvious

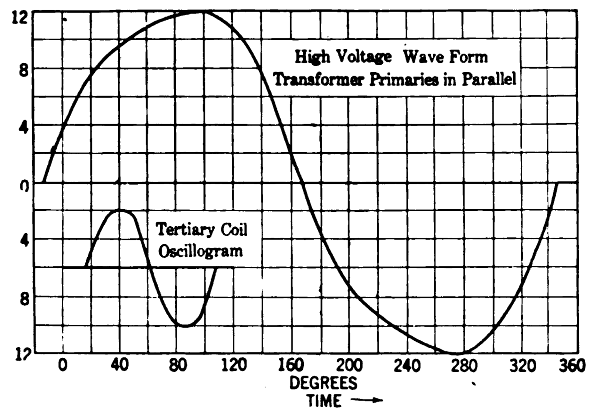

FIG. 5—HIGH-VOLTAGE WAVE FORM

reasons this disturbance is more pronounced in the half-wave measurements in which the galvanometer is used as a half-wave suppressor.

The curves of Figs. 4 and 5 were each taken at the critical or corona-forming voltage using the same corona rod and equal values of air density. Although there are noticeable differences in wave form and in

TABLE I.

WAVE FORM OF HIGH VOLTAGE

Brushes degrees	Galvanometer deflection cm.					
	Full wave			Half wave		
	Left	Right	Mean	Left	Right	2 X Mean
22.5	7.80	7.76	7.78	3.72	4.10	7.82
30	8.41	8.47	8.44	4.09	4.39	8.48
37.5	9.14	9.10	9.12	4.42	4.70	9.12
90	11.91	11.87	11.89	5.87	6.03	11.90
120	10.68	10.60	10.64	5.32	5.30	10.62

the values of effective voltage at the terminals of the tertiary coil (38 volts and 34.5 volts respectively) it is seen that the maxima of the two waves have very closely the same values. Further evidence that no error was present due to irregularities of wave form is found below in the comparison of corona readings taken with kenotrons and with commutator.

High-Tension Insulator Porcelain

W. D. A. PEASLEE

Electrical Engineer, Jeffery Dewitt Insulator Co., Huntington, W. Va.

Porcelain used in the manufacture of high-tension insulators must meet certain requirements as to mechanical strength, ability to resist, sudden changes of temperature, porosity, homogeneity and temperature, coefficient of resistivity. A further suggestion as to the influences of the Piezo electric effect and the deterioration of seemingly perfect porcelain is presented with a brief discussion of the degree of progress made in the art to date.

Introduction

While in the case of transmission line insulators it is true that the design of the insulators insofar as the utilization of the material is concerned is a matter of most efficient design of air insulators, that is, the boundary surface between the air and the supporting dielectric, the material of the insulator itself becomes of greater importance as the voltage of the line increases.

The shape design of the insulator will not be discussed here as that subject is reserved for a later communication. It is hoped that the following discussion of the factors affecting the material employed in the manufacture of high-tension insulators as a dielectric, may lead engineers to a more serious consideration of this vitally important question. The discussion is confined to porcelain as for many reasons this material has come to be accepted as the best for high-tension insulators.

Factors to be Considered in the Selection of a Porcelain Body as a Material for High-Tension Insulators

Mechanical Strength. It is perfectly obvious that mechanical strength is one of the prime factors to be considered in an insulator material. One of the first duties of an insulator is to support the conductor, and it must do so under any conditions not severe enough to destroy some other element of the transmission line construction.

Insulators made today either in pin or suspension types, use porcelain either in compression or tension or both, and so it is of great importance to know the strength of porcelain under these conditions.

Porcelain being a brittle or rigid substance like cast iron, has no yield point as commonly known, and its first yield is complete rupture. There seems to be no indication that the stressing of porcelain to a point close to its ultimate strength injures it either mechanically or electrically. Indeed, the accumulated evidence of a large number of tests covering combined electrical and mechanical tests, fatigue tests and high-frequency tests indicate that such stressing has no effect whatever upon these properties. It is probably quite safe to say that properly vitrified porcelain must be stressed beyond its ultimate strength to rupture it even under repeated strains. Tension and compression tests both confirm this statement.

It is, therefore, immaterial whether the porcelain be used for compression or tension, provided that maximum momentary stress does not reach the ultimate strength of porcelain. For engineering reasons an ample safety factor must always be provided for. Ordinary porcelain, made up of the usual three ingredients,—clay, flint and feldspar— has been found by several investigators to have strengths reaching as a maximum 40,000 lb. per sq. in. for compression and 1500 lb. per sq. in. for tension. Naturally different proportions of these ingredients produce a porcelain, or to use a ceramic term, "Body," (which covers all bodies made up of the above or similar ingredients and vitrified) of somewhat different mechanical characteristics, but these figures cover rather the upper limit of strength for a body having the required characteristic as to dielectric qualities and ability to withstand sudden temperature changes.

The wide difference between these values has led many engineers to distrust porcelain used under tension, but provided the stresses are kept within the proper limits, from an engineering safety factor point of view, there is no more valid ground for this attitude than there is to condemn cast iron whenever used in tension.

Under the stimulus of the demand by transmission engineers for better insulation a great deal of work has been done on porcelain mixtures or bodies, and certain types are now available, whose strength runs up to 65,000 lb. per sq. in. in compression and 12,500 lb. per sq. in. in tension. This, indeed, is not the ultimate limit, as indications point to the commercial production of bodies with even greater strength which will at the same time retain the other necessary requirements.

In making tension and compression tests on porcelain it is very necessary that the application of the stress be made in such a manner as to place the porcelain either in pure compression or tension as desired. The compression tests are made on small blocks and the pressure applied through lead or blotting paper disks. The tension tests are made on test pieces consisting of a short, straight section of accurately determined area between two conical end pieces. These conical end pieces are gripped in a specially designed multiple part clutch faced with soft lead or blotting paper sheets; and remarkably consistent results are obtained in this manner.

Ability to Resist Sudden Changes in Temperature. A great many insulator failures are traceable directly

To be presented at the Annual Convention of the A. I. E. E., June 29, 1920.

to the inability of certain porcelain bodies to resist sudden changes in temperature. The first rays of sunlight on a frosty morning have often been the signal for insulator failures directly attributable to this weakness.

Also a body sensitive to this change is more difficult to manufacture reliably as it will develop internal strains which, added to the applied service strains, will produce rupture of the porcelain at very low applied loads. The existence of these strains has been shown by polarized light under microscopic examination.

Any mixture or body that in the shape and size employed will not, when completely equipped with hardware, withstand an indefinite number of alternate immersions in boiling and freezing water, should never be employed in the manufacture of high-tension insulators. This test should be insisted upon by purchasing engineers. Such bodies are made today, and some are made that will stand even greater ranges. At least two are known which can be heated red hot and thrown into a bucket of water without cracking.

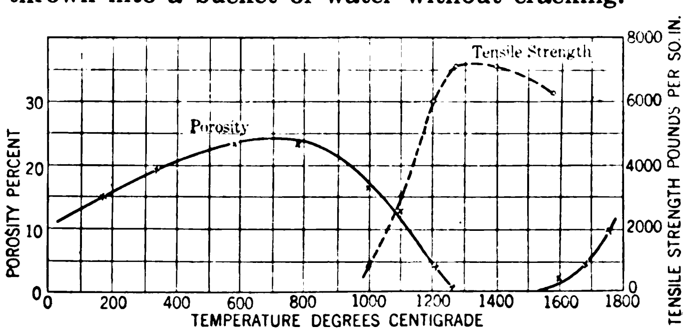

FIG. 1—POROSITY AND TENSILE STRENGTH CHARACTERISTICS—SPECIAL PORCELAIN BODY

Porosity. Porous porcelain is responsible to a large degree for the unsatisfactory condition of the insulator situation of today. One of the greatest insulator manufacturers has recently stated in a published article that non-porous porcelain cannot be produced.

This statement is challenged as the writer's investigations, both in this country and in the laboratories of France, indicate that it can be produced and under manufacturing conditions. Porcelain can be, and is, produced today that is in an engineering sense, absolutely non-porous. This statement is made after a great deal of careful research and on the strength of many porosity tests both by the impregnation method and the method used in ceramic analysis with a psychometer and a sample crushed to a 100-mesh fineness. The impregnation test has been carried in our laboratories to very high pressures, and is so penetrating that, under microscopic examination of the penetration of the colorant material, it has been observed in the cleavage cracks of microscopic quartz crystals.

Furthermore, a body having the slightest porosity, as indicated by the psychometer test, shows a decided penetration under the impregnation test.

Porosity is of two kinds, discussed in ceramic language as open pore and closed pore types. In the open pore type the pores or voids are connected by capillary passages, while in the second, or closed pore type, the voids or pores are isolated. Though the percentage of porosity may be the same in the two cases, it is obvious that the general character of porosity and its effect on insulators is different in the two cases. In general, the first form is a product of under-firing and the second of over-firing, though many instances have been found wherein over-firing produces the first type of porosity. There are probably many ceramists even today, who will dispute the statement that over-firing will produce porosity, but it can be very readily demonstrated by proper tests. In this connection the curve of Fig. 1 shows the behavior of one mixture or body and indicates very well the effect of the temperature of firing on the porosity of the body. The porosity developed on over-firing on this body was of the closed pore type and on under-firing of the open pore type. In securing the data for making this curve the samples were fired to given temperatures and cooled, and the porosity and tensile strength values were taken at room temperature. In other words the points on the curve represent maximum temperature of firing of each sample and not the temperature of the test. The porosity determinations were made by the psychometer method, the impregnation method being in any case merely qualitative.

In practise the effect of open pore type of porosity is too well-known to discuss here. The development of megger and buzz stick tests are ample evidence of the degree to which this factor has entered into the troubles encountered in the insulator field. Tests to determine porosity in units at the factory are needed, and the man who develops a method whereby we can detect porous insulators at the factory without destroying them, will be a true benefactor of the transmission engineers and porcelain manufacturers.

In the production of insulators a method has been developed that is very valuable in production control testing. A solution of fuchsine dye in wood alcohol is used and unglazed pieces placed in it under pressure. The slightest degree of porosity of the open pore type is indicated by a deep penetration of the dye into the body of the test piece. Indeed, as mentioned before, it is so penetrating that the microscope has shown it forced into the cleavage cracks of minute quartz crystals. If test pieces of the same shape and volume as the insulators being fired are properly distributed in the kiln the fuchsine test on these pieces will furnish a very reliable indication of the condition of neighboring pieces as to porosity.

Some very interesting developments have recently been brought out by the use of very high pressures on the solubility of porcelain in water under certain conditions, and it is probable that considerable light will soon be thrown upon certain types of insulator depreciation as a result of these developments.

It has been found possible to produce insulators of non-porous porcelain within the ordinary limits of quantity manufacture and by means of this method of control to prevent the porous insulators, a few of which are unavoidable in commercial manufacture, from going to the customers. Closed pore porosity is commonly indicated by a swelling of the insulators, and can be watched closely by gauges applied to the finished product.

Temperature Resistivity Coefficient. The temperature resistivity coefficient of porcelain is large and negative. The curves of Fig. 2 give an idea of this characteristic and of the improvement that has been made in it. The curve marked "Conventional Porcelain" in Fig. 2 is the standard mixture of clay, flint and feldspar, and the curve marked "New Body" is one of the recent developments, the formula for which naturally cannot be disclosed. In this curve the points on the curve represent measured resistance attained at the temperatures noted by the abscissas of the curve. For instance, a certain sample of conventional porcelain will have a resistance of two megohms at slightly over 700 degrees fahr. (371 deg. cent.) whereas the "New Body" in an exactly similar piece has a resistance of two megohms at 1160 degrees fahr. (627 deg. cent). These curves will give some idea of the progress that has been made in this respect. The importance of this feature has been discussed by various writers, and it must be stated here that this characteristic may be improved but will always be negative even in pure quartz. It has an important bearing on the mechanism of insulator failures under transient voltages. This has been discussed by the writer in previous papers before the institute.[1]

Piezo Electric Effect. One of the most baffling difficulties in the insulator situation is the deterioration of seemingly perfect units after a time, and the acquiring by non-porous porcelain of a certain porosity. Some recent investigations indicate that this may be intimately connected with Piezo electric qualities of quartz crystals. Under the microscope it will be seen that porcelain as ordinarily made, consists of rather large particles of quartz in a vitreous magma. It is well-known that if certain crystals such as quartz are subjected to a pressure on two diametrically opposite faces which are parallel with the major axes, a potential difference is set up on the faces perpendicular to those upon which the pressure is applied, which varies directly as the pressure.

The converse of this is also true and if a difference of potential is applied to two opposite faces parallel to the major axes the crystal is subjected to a squeezing action and a change in dimensions of the crystal results. These changes in dimensions if strongly resisted by the surrounding magma will set up enormous local stresses beteen the magma and the crystals.

Now what happens when this porphyritic mass is placed in an alternating electro-static field? According to the theory of probabilities a large number of these quartz crystals are so arranged that their major axes are not parallel to the field of force. This alternating field applying potentials as described will set up in these crystals a change in mechanical dimensions 120 times per second in the case of a 60-cycle system. This will result in a vibratory movement of these crystals. This vibratory action may be detrimental in two ways,—first a rupture of the crystal itself, along cleavage planes, and second a rupture between the crystals and the surrounding magma.

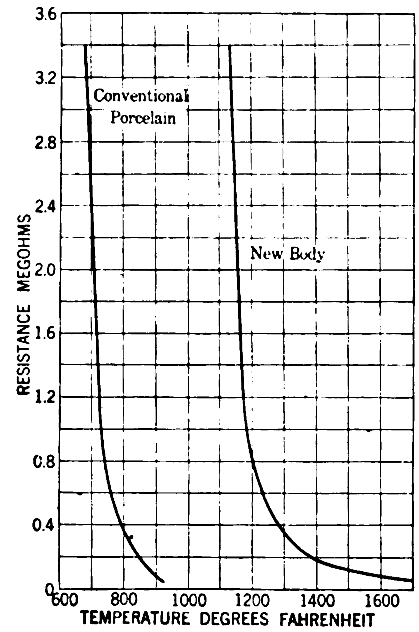

Fig. 2—Temperature Resistance Characteristics of Conventional and New Bodies

A concentrated leakage current results through the spaces between the magma and the crystals when the crystal is at its greatest deformation and the potential differences are at maximum. It will also tend towards making the porcelain porous in an entirely different manner (that is, by cracks and fracture voids) from the types before mentioned and the vibratory action of the crystals may aid in the introduction of moisture into the body. This decreases its value as a dielectric and as mentioned before the solvent action of such moisture may have an accelerating effect upon the deterioration of the porcelain.

Regardless of the degree to which this effect contributes to the deterioration of the porcelain when in service on high-tension lines the body to be sought is one wherein the quartz is dissolved as completely as possible in the feldspathic magma.

Great progress has been made in this direction and in a later communication some data, which is now

1. "Insulator Failures Under Transient Voltages," W. D. A. Peaslee, A. I. E. E. Transactions, page 1237, Vol. 35; "Insulator Situation....," W. D. A. Peaslee, A. I. E. E. Transactions, page 401, Vol. 36.

being prepared, may be given that it is hoped will be of some help in the solution of this ever present problem.

CONCLUSION

The insulator problem at present is one whose solution is to be sought in the ceramic field. Aside from more rational shape design on the part of electrical engineers, the improvement must come in the development of porcelain bodies which meet, to the greatest degree possible, the above requirements. Great progress has been made in this respect and the statement that we may very soon see the commercial production in insulator form of such bodies is now amply warranted.

Reactive Power and Magnetic Energy

BY JOSEPH SLEPIAN

Research Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

The relation between reactive power and magnetic and electrostatic energies is stated and proved and its utility is illustrated by deriving the connection between reactive power and the size of machines, between the magnetic energy of an a-c. system and the field excitations of the synchronous machines therein, and by giving the physical significance of power factor under unbalanced conditions.

IT is a matter of common knowledge that where a magnetic field is maintained by alternating currents, reactive or wattless power must be supplied. The exact quantitative relation between the reactive power and the magnetic field is not so generally understood, probably because the proportionality is between reactive power and total magnetic energy, and this last quantity is not often used by electrical engineers. In this paper a quantitative statement of the relation is given, and its utility is illustrated by several examples.

The relation which is given here is subject to certain limitations which are brought out in the appendix where the proof of the relation is given. For practical purposes the relation may be said to hold for all combinations of condensers, resistors, and inductive apparatus, stationary, oscillating, rotating, single-phase or polyphase, balanced or unbalanced, excepting commutator and homopolar machines.

To state the relation, suppose we have any combination of apparatus of the kind just described, with an arbitrary number of terminals having certain periodically varying potentials, and carrying certain periodically varying currents. These periodically varying potentials and currents may be resolved in the usual way into pure sine-wave components of different frequencies. For each frequency, the reactive power at each terminal may be calculated in the usual way. If now the reactive powers of each frequency are divided by the frequency, and the whole added together, the result equals 4 π times the mean magnetic energy minus the mean electrostatic energy.

$$\sum \frac{\text{Reactive power}}{\omega} = 2\,(T_m - T_e)$$

If there is only one frequency, the relation reduces to

$$\text{Total reactive power} = 2\,\omega\,(T_m - T_e)$$

which has been derived for static apparatus before.[1] The mean is taken with respect to time. In balanced polyphase machines the total magnetic and electrostatic energies are nearly constant at all parts of a cycle, but in unbalanced polyphase and single-phase machines the electrostatic and magnetic energies have large pulsations with frequency twice that of the supply line.

Where there is a d-c. component of voltage and current, both the reactive power and the frequency are zero, so that indeterminate forms appear in the relation as given. In this case, as is shown in the appendix, these terms should be replaced by $\Sigma\,\Phi\,I\,.\,\frac{1}{10^8}$ where I is the d-c. component of current flowing in any coil or branch, and Φ is the d-c. component of flux linking that coil or branch.

REACTIVE POWER AND THE SIZE OF MACHINES

Magnetic energy is believed to reside wherever there is a magnetic flux, the energy being distributed throughout the magnetic field. The magnetic energy density is given by $\frac{1}{8\,\pi}\,.\,\frac{B^2}{\mu}\,10^{-7}$ joules per cm.^{3}, where B is the flux density and μ is the permeability. This gives a direct relation between the reactive power taken by an induction machine without d-c. excitation, and its general dimensions. For such a machine, if currents of one frequency are supplied, we have

Total Reactive Power = 2 ω (Mean magnetic energy

On the other hand,

Mean magnetic energy

$$= \frac{10^{-7}}{8\,\pi}\left[\frac{(\text{Volume of iron}) \times (\text{Mean } B^2 \text{ in iron})}{\mu} + (\text{Volume of air gap}) \times (\text{Mean } B^2 \text{ in air gap})\right]$$

To be presented at the Annual Convention of the A. I. E. E., June 29—July 2, 1920.

[1] 1. Inherent Limitations in Transformations Possible by Static Apparatus, J. Slepian, A. I. E. E. TRANSACTIONS, 1919.

Hence,
Total Reactive Power

$$= \frac{10^{-7} f}{2} \left[\frac{(\text{Volume of iron}) \times (\text{Mean } B^2 \text{ in iron})}{\mu} + (\text{Volume of air gap}) \times (\text{Mean } B^2 \text{ in air gap}) \right]$$

This relation was discovered independently by Mr. H. G. Jungk, from calculations on a line of railway motors.[2]

A similar relation connects the reactive power supplied by a condenser, and the volume of its dielectric. Since electrostatic energy density is given by

$$\frac{10^{-7} D^2}{8 \pi \epsilon} \text{ joules/cm.}^3$$

where D is the electric flux density, and ϵ the dielectric constant, we have
Reactive Power taken by Condenser

$$= f/2 \left(\frac{\text{Volume of dielectric} \times \text{Mean } D^2}{\epsilon} \right) . 10^{-7}$$

Energy of an A-C. System and the Current Flux Linkages of its Field Circuits

An interesting connection between the total magnetic energy of an alternating-current system and the exciting direct currents may be found by applying the principle of this paper to a whole a-c. system. In making this application, we must exclude the exciters, because they are commutator machines to which the principle does not apply. Hence the field terminals of the generators, and synchronous motors are the terminals to which the principle refers, the circuits of all other current-carrying members being closed in the system itself, thus giving no external terminals. We get then

$$\frac{1}{10^8} \Sigma \Phi I \text{ for all d-c. fields in system}$$
$$= 2 \text{ (Total Mean Magnetic Energy of System Minus Total Electrostatic Energy of System)}$$

Let us take a specific example. Suppose we have a generator whose field is controlled so as to give constant voltage. This means of course, that the main flux is nearly constant. On open circuit, the only magnetic energy is that corresponding to the main flux, and the field current is such as to make $\Sigma \Phi I$ take the appropriate value,

$$\frac{1}{10^8} \Sigma \Phi I = 2 \times \text{(Energy of main flux)}$$

Suppose now a unity power factor load is drawn from the generator. The main flux must be increased somewhat to keep the voltage at the armature terminals constant, and at the same time, additional magnetic energy appears in the form of leakage flux of the armature. The corresponding field current satisfies the relation

$$\frac{1}{10^8} \Sigma \Phi I = 2 \text{ (Energy of main flux + Energy of leakage flux)}$$

If a zero per cent power factor lagging load is substituted for the unity power factor load just considered, the exciter current must be further increased due to the magnetic energy of the load.

$$\frac{1}{10^8} \Sigma \Phi I = 2 \times \text{(Energy of main flux + Energy of leakage flux + magnetic energy of load.)}$$

If a condenser load is drawn, the exciter current must be decreased corresponding to the equation

$$\frac{1}{10^8} \Sigma \Phi I = 2 \times \text{(Energy of main flux + Energy of leakage flux} - \text{electrostatic energy of load.)}$$

If the generator is self-exciting on the capacity load, I is zero, and from the last relation we get as a necessary condition for self-excitation,

Electrostatic Energy of Capacity Load
= Magnetic Energy of System.

Consider a generator A, supplying a synchronous motor B. If the voltage at the generator is kept constant, the magnetic energy in each machine is nearly constant, varying somewhat by the amount of leakage flux. If B is without excitation, we must have

$$\frac{1}{10^8} \Sigma \Phi_A I_A = 2 \text{ (Magnetic energy of } A + \text{Magnetic energy of } B)$$

When B is excited, the field current of A must receive a corresponding diminution as we must have

$$\frac{1}{10^8} \Sigma \Phi_A I_A + \frac{1}{10^8} \Sigma \Phi_B I_B = 2 \text{ (Magnetic energy of } A + \text{Magnetic energy of } B.)$$

The mutual dependence of the field currents of synchronous machines operating in parallel on a system is thus clearly shown.

Power-factor Under Unbalanced Conditions. Vectorial Kv-a. Sum Formula

Under balanced conditions power factor is defined as the cosine of the acute angle of a right triangle having for adjacent and opposite sides respectively, the total true power and total reactive power of the circuits being measured (Fig. 1). For unbalanced circuits no definition has been generally agreed upon.

It has been proposed as one definition, to construct kv-a. triangles for each phase, using line current and

2. The relation as found by Mr. Jungk is
Total Magnetising kv-a. = $B^2 S g f \times$ sat. factor $\times 10^{-11}$
where B = max. density lines /in²
$S = \pi D L$, air gap surface in square inches.
g = effective gap, one side, in inches.
f = frequency
sat. factor $= \dfrac{\text{ampere turns, Iron + gap}}{\text{ampere turns, gap}}$

voltage to neutral, then to add the hypotenuses of these triangles vectorially, and to take the cosine of the angle of this resultant as the power factor. It is clear from Fig. 2 that the triangle corresponding to this resultant has for its base the sum of the true powers supplied to the individual phases, and for its altitude the sum of the reactive powers supplied to the individual phases.

This definition has the advantage that the quantities it uses have actual physical significance. The base of the triangle gives the total real power supplied to the load being measured, and the altitude gives the excess of the mean magnetic energy of the load over the mean electrostatic energy. A pure resistance load according to this definition will always have one hundred per cent power factor irrespective of the unbalance of the load resistances or impressed voltages.

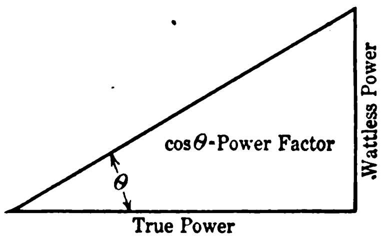

FIG. 1

Under this definition, however, all apparatus will not have this property of giving the same power factor irrespective of voltage unbalance. Rotating induction machines are particularly sensitive in this respect, and when measured according to this definition would show very low power factor when operated under unbalanced voltages. The conditions in a rotating induction machine can best be understood and analyzed by resolving the unbalanced quantities into polyphase or symmetrical components.

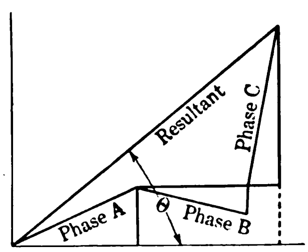

FIG. 2

For clearness let us consider a three-phase induction motor, with low-resistance secondary, running at small slip, with ungrounded neutral, so that voltages tending to produce neutral currents may be neglected. It has been shown[3] that the voltages impressed upon the motor terminals, however unbalanced, may be regarded as two component systems superimposed or simultaneously impressed; the component systems are each individually balanced three-phase voltages, but one is of normal or positive phase sequence, while the other is of opposite, or negative, or counter-rotational phase sequence. A given unbalanced three-phase voltage can be resolved into these symmetrical components in only one way. In ordinary slightly unbalanced systems, the negative or counter-rotational component of voltage is small. It has been shown for the induction motor[4] that each symmetrical component of voltage may be considered as acting as if the other component were absent. Thus to calculate the currents in the different phases of the motor under unbalanced voltage, we may calculate the currents which each symmetrical component of voltage would produce were it acting alone, and then add these two current systems together as they appear in the different phases. The problem of operation under unbalanced voltage is thus reduced to two problems under balanced voltages. The direct-rotational or positive phase sequence voltage produces direct-rotational currents; the counter-rotational voltage produces counter-rotational currents. These are the two symmetrical components of the resultant unbalanced currents. To get the unbalanced resultant currents we add together in each phase the currents corresponding to the two symmetrical components.

As with currents, so with fluxes. Each component of voltage produces flux as if the other component of voltage were absent. The resultant flux distribution under unbalanced voltage may be obtained by combining the fluxes corresponding to each component of voltage taken separately. It may be shown[5] that the mean magnetic energy of the resultant flux is equal to the sum of the magnetic energies of the fluxes corresponding to the polyphase components taken separately.

When running at a small slip, the direct-rotational flux consists mostly of the synchronous direct-rotating main flux and a small leakage flux. Because most of the magnetic energy here resides in the main flux, a relatively high direct-rotational voltage is necessary to maintain it. The counter-rotational components, however, are all at nearly 200 per cent slip relative to the rotor, and therefore, owing to the magnetic damping of the rotor, the counter rotational flux consists mostly of leakage flux between primary and secondary, and to a small extent of counter-rotating main flux. A relatively small counter-rotational voltage therefore may produce considerable counter-rotational magnetic energy.

The conditions for reducing the magnetic energy, and thus giving good power factor, under direct-rotational voltage, *e. g.* small air gap, good magnetic coupling between primary and secondary windings, etc., are just the conditions for giving excessive magnetic energy and low power factor under counter-ro-

3. Fortescue, A. I. E. E. TRANS. Vol. XXXVII p. 1027, 1918.

4. Fortescue loc. cit.

5. Slepian, A. I. E. E. TRANS. Vol. XXXVII, 1918 Discussion, p. 661.

tational voltage. An induction motor designed for a high power factor under normal balanced voltage conditions, would, if measured according to the vectorial kv-a. definition, show a low power factor under voltages which are only slightly unbalanced.

A case in point was brought to the attention of the author, where a synchronous converter was sold with the guarantee of giving 100 per cent power factor at rated load. The leads from the transformers to the slip rings were installed by the customer in an unsymmetrical way, causing a considerable unbalance in the voltages at the slip rings. The power factors taken from the three diametrical pairs of rings were all different, and the question arose as to what would represent 100 per cent power factor. It was finally agreed that the guarantees would be met if 100 per cent were maintained on one diameter, with equal power factors on the other two, leading on one, and lagging on the other. Since the kv-a. in all the leads were nearly equal, this was evidently equivalent to adopting the vectorial kv-a. definition of power factor.

It is clear from the preceding discussion that this was unfair to the manufacturer. Under the test conditions agreed upon the field excitation was raised high enough to have given leading power factor if the voltages had been balanced. With the voltages unbalanced the rotary was taking a large counter-rotational magnetic energy, and therefore correspondingly large counter-rotational reactive current. It was then called upon to give an equal amount of direct-rotational reactive current, but leading, which meant leading direct-rotational power factor and higher field excitation than the manufacturer had anticipated. Stated in another way, at unity power factor under this definition we have if i is the field current

$$\frac{1}{10^8} \Sigma \, \phi \, i = 2 \text{ (Total magnetic energy)}$$

If the voltages are balanced, all this energy is direct-rotational,

$$\frac{1}{10^8} \Sigma \, \phi \, i = 2 \text{ (Direct-rotational magnetic energy)}$$

A slight voltage unbalance will give considerable counter-rotational magnetic energy, and this calls for a considerable increase in field current since

$$\frac{1}{10^8} \Sigma \, \phi \, i = 2 \text{ (Direct-rotational magnetic energy + counter-rotational magnetic energy)}$$

Power Factor Under Unbalanced Conditions. Direct-Rotational Component Definition

If rotating machines are to be given a power factor descriptive of their operation under normal conditions, it is evident that some definition other than that of the preceding section must be used when measurements are made under unbalanced conditions. In the light of the preceding discussion, the following would appear to be a satisfactory definition of power factor, under unbalanced voltage conditions, of a balanced rotating machine. Power factor is the cosine of the angle of lag between the direct-rotational component of voltage and the direct-rotational component of current. Methods for determining from the observed unbalanced voltages and currents, the direct-rotational components and the angle between them are beyond the scope of this paper. With this definition, a balanced rotating machine will show the same power factor irrespective of the voltage unbalance.

Fig. 3

What is the state of affairs, however, when this definition is applied to apparatus which is inherently unbalanced? This is best brought out by a simple example. A three-phase generator, $\frac{110}{\sqrt{3}}$ volts to neutral, is supplying a pure resistance load of one ohm, across one phase. What are the line voltages, currents, and the power factor under the last definition in this case? The power factor under the first definition, of course must be 100 per cent. The current through the resistance will be 110 amperes. The currents in the three lines will be as shown in Fig. 3, line A I_A = 110 amperes; line B, I_B = − 110 amperes; line C,

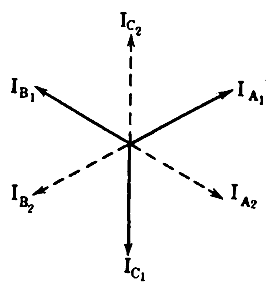

Fig. 4

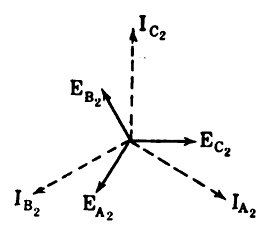

Fig. 5

I_C = 0 amperes. Resolving these currents into symmetrical components, we get for the direct-rotational component (heavy lines, Fig. 4) line A, $I_{A1} = 55 + 55\sqrt{3}\,j$ amperes; line B, $I_{B1} = -55 + 55\sqrt{3}\,j$ amperes; line C, $I_{C1} = -110\sqrt{3}\,j$ amperes. For the counter-rotational component we have (dotted lines, Fig. 3) line A, $I_{A2} = 55 - 55\sqrt{3}\,j$ amperes; line B, $I_{B2} = -55 - 55\sqrt{3}\,j$ amperes; line C, $I_{C2} = +110\sqrt{3}\,j$ amperes.

The counter-rotational currents, (I_{A2}, I_{B2}, I_{C2}) when drawn from the generator, produce counter-rotational voltages at the terminals (E_{A2}, E_{B2}, E_{C2}), which lag nearly 90 deg. behind the currents, see Fig. 5. The magnitude of the counter-rotational voltage wil

depend upon the closeness of coupling between the armature of the generator and the damper winding on its field. The magnitude of the direct-rotational voltage depends upon the field excitation. Suppose this is adjusted to give 110 volts total between lines A and B. From this condition, since further this voltage must be in phase with the current through the resistance, the direct-rotational voltage (E_{A1}, E_{B1}, E_{C1}) is readily determined (Fig. 6.). In Fig. 6, we see that the direct-rotational current lags behind the direct-rotational voltage so that the pure resistance load actually draws direct-rotational reactive power. Thus its power factor according to the direct-rotational component definition would be less than 100 per cent. From Fig. 5 we see that all the counter-rotational power is leading reactive power. This might have been foreseen, for since the total reactive power taken by the resistance load is zero, whatever is taken in direct-rotational form must be returned to the line in counter-rotational form.

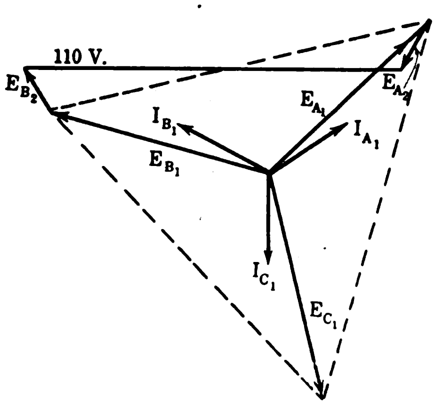

FIG. 6

The field excitation will be that corresponding to the direct-rotational voltage, current, and power factor. It is thus larger than that which would be required for an equal load which is balanced. This is because with the unbalanced load there is actually more magnetic energy in the system. The unbalanced resistance load, while containing no magnetic energy itself, causes counter-rotational magnetic energy to exist in the system. This affects the field excitation according to the equation,

$\Sigma \phi i = 2$ (Direct-rotational magnetic energy + counter-rotational magnetic energy.)

where $\Sigma \phi i$ represents the total flux-current linkages of the field of the generator. By the direct-rotational component definition, in this case, the power factor of the unbalanced resistance load is dependent upon the constants of the generator.

It is not intended that this paper shall advocate any particular definition of power factor for unbalanced conditions, but merely to point out the meaning of two definitions which have been proposed. However, there seems little doubt that for rotating balanced machines, the direct-rotational component definition is the best. For unbalanced stationary apparatus, for example polyphase furnaces, it seems likely that the vectorial kv-a. formula is preferable. For this class of apparatus, a further term, an unbalance factor, would appear desirable for giving adequate description.

Power factor has been used in this paper as characterizing a piece of apparatus. It is also widely used to describe a load from the point of view of the cost of its generation and transmission. Here the considerations are somewhat different, but here also the principle connecting wattless power with magnetic energy will prove useful in discussions.

APPENDIX

PROOF OF RELATION CONNECTING REACTIVE POWER AND MAGNETIC AND ELECTROSTATIC ENERGIES

A few well-known propositions concerning the mean value of products of periodic quantities, and some expressions for magnetic and electrostatic energy which are used in the proof will first be given.

Expansion of a Periodic Quantity into a Fourier Series. Any periodic quantity can be expanded into a series of the following form,

$$y = a_0 + a_1 \sin(\omega t + \alpha_1) + a_2 \sin(2\,\omega t + \alpha_2) + \ldots$$

Each term of the expansion is called a harmonic.

Mean Value of the Product of Two Periodic Quantities. The mean value of the product of two periodic quantities is equal to the sum of the mean values of the products of harmonics of the same frequencies in the Fourier expansions of the two periodic quantities. Thus if

$$y = a_0 + a_1 \sin(\omega t + \alpha_1) + a_2 \sin(2\,\omega t + \alpha_2) + a_3 \sin(3\,\omega t + \alpha_3) + \ldots$$

$$z = b_0 + b_1 \sin(\omega t + \beta_1) + b_2 \sin(2\,\omega t + \beta_2) + b_3 \sin(3\,\omega t + \beta_3) + \ldots$$

then

$$\begin{aligned}\text{Mean of } y\,z &= a_0\,b_0 + \text{mean of } a_1\,b_1 \sin(\omega t + \alpha_1)\sin(\omega t + \beta_1)\\ &\quad + \text{mean of } a_2\,b_2 \sin(2\,\omega t + \alpha_2)\sin(2\,\omega t + \beta_2)\\ &\quad + \text{mean of } a_3\,b_3 \sin(3\,\omega t + \alpha_3)\sin(3\,\omega t + \beta_3)\\ &\quad \text{etc.}\\ &= a_0\,b_0 + \tfrac{1}{2}\,a_1\,b_1 \cos(\alpha_1 - \beta_1)\\ &\quad + \tfrac{1}{2}\,a_2\,b_2 \cos(\alpha_2 - \beta_2)\\ &\quad + \tfrac{1}{2}\,a_3\,b_3 \cos(\alpha_3 - \beta_3)\\ &\quad \text{etc.}\end{aligned}$$

Magnetic Energy. The magnetic energy of the field produced by a system of currents is given by

$$t_m = \frac{1}{2.10^8}\,\Sigma\,\phi\,i$$

$$= \frac{1}{2.10^8}\,(\phi_1\,i_1 + \phi_2\,i_2 + \phi_3\,i_3 + \ldots)\text{ joules}$$

where each term is the product of i_K the current in a branch or circuit of the system, and ϕ_K the number of

flux linkages of that branch or circuit; the summation is taken for all the branches and circuits of the system.

Electrostatic Energy. The electrostatic energy of a condenser is given by $t_e = \frac{1}{2}\frac{q^2}{C}$ joules where q is the charge in coulombs and C the capacity of the condenser in farads.

Proof of the Relation. For any branch or circuit of the system we have

$$e = r\,i + \frac{1}{10^8}\frac{d\phi}{dt} + \frac{q}{C} \qquad (1)$$

where i is the current in the branch or circuit, ϕ the flux linking the branch or circuit, q the charge on the condenser in that branch or circuit, and e the difference of potential between the ends of the branch or circuit. If the circuit is a closed loop, $e = 0$. The quantities in equation (1) are periodic, and their Fourier expansions in general will contain constant terms. Suppose these constant terms subtracted out from equation (1) leaving

$$e_A = r\,i_A + \frac{1}{10^8}\frac{d\phi_A}{dt} + \frac{q_A}{C} \qquad (2)$$

where e_A, i_A, ϕ_A, and q_A are the purely alternating parts of e, i, ϕ, and q respectively remaining after the constant terms of the Fourier expansions of these quantities have been subtracted.

Now integrate equation (2) taking that integral which is periodic. (This merely fixes the constant of integration.)

$$\int e_A\,dt = r\int i_A d\,t_A + \frac{1}{10^8}\phi_A + \frac{1}{C}\int q_A\,dt \quad (3)$$

Multiplying through by i_A and remembering that

$$i_A = \frac{d\,q_A}{d\,t}$$

$$i_A \int e_A\,dt$$

$$= r\,i_A \int i_A d\,t + \frac{1}{10^8}\phi_A\,i_A + \frac{1}{C}\frac{d\,q_A}{d\,t}\int q_A d\,t \quad (4)$$

Suppose equations similar to (4) found for all the branches or circuits of the system, and that they are all added together, giving

$$\Sigma\, i_A \int e_A\,dt = \Sigma\, r\,i_A \int i_A\,dt + \frac{1}{10^8}\Sigma\, i_A\,\phi_A$$

$$+ \Sigma\frac{1}{C}\frac{d\,q_A}{dt}\int q_A\,dt \qquad (5)$$

We may now take the mean value of each term of (5) getting

Mean value of $\Sigma\, i_A \int e_A\,dt$

= mean value of $\Sigma\, r\,i_A \int i_A\,dt$

+ " " " $\frac{1}{10^8}\Sigma\,\phi_A\,i_A$ (6)

+ " " " $\Sigma\frac{1}{C}\frac{d\,q_A}{dt}\cdot\int q_A\,dt.$

We now proceed to evaluate each term of (6).

The first term

$$\Sigma i_A \int e_A\,dt.$$

Let

$i_A = i_1 \sin(\omega t + \alpha_1) + i_2 \sin(2\,\omega_2 t + \alpha_2) + \ldots;$

let

$e_A = e_1 \sin(\omega t + \beta_1) + e_2 \sin(2\,\omega t + \beta_2) + \ldots$

Then

$$\int e_A\,dt = -\frac{e_1}{\omega}\cos(\omega t + \beta_1)$$

$$- \frac{e_2}{2\,\omega}\cos(2\,\omega t + \beta_2)\ldots$$

Hence it follows that the mean of

$$i_A \int e_A\,dt = \Sigma\frac{\text{Reactive Power}}{\omega}$$

supplied to the branch under consideration. It is readily seen that when we sum up for all the branches we get $\Sigma\frac{\text{Reactive Power}}{\omega}$ for the terminals of the system. Hence

$$\text{Mean value of } \Sigma\, i_A \int e_A\,dt = \Sigma\frac{\text{Reactive Power}}{\omega}.$$

The next term

$$\Sigma\, r\,i_A \int i_A\,dt.$$

Let

$i_A = i_1 \sin(\omega t + \alpha_1) + i_2 \sin(2\,\omega t + \alpha_2) + \ldots$

Then

$$\int i_A\,dt = -\frac{i_1}{\omega}\cos(\omega t + \alpha_1)$$

$$- \frac{i_2}{2\,\omega}\cos(2\,\omega t + \alpha_2)\ldots$$

Evidently then the mean value of $i_A \int i_A\,dt$ is zero. Hence

$$\text{Mean value of } \Sigma\, r\,i_A \int i_A\,dt = 0.$$

The next term

$$\frac{1}{10^8}\Sigma\, i_A\,\phi_A.$$

The instantaneous magnetic energy t_m is given by

$$t_m = \frac{1}{2.10^8}\Sigma\,\phi\,i = \frac{1}{2.10^8}\Sigma\,(\phi_D + \phi_A)(i_D + i_A)$$

$$= \frac{1}{2.10^8}[\Sigma\, i_D\,\phi_D + \Sigma\,\phi_A\,i_A + \Sigma\,\phi_A\,i_D + \Sigma\,\phi_D\,i_A]$$

where ϕ_D and i_D are the constant terms of the Fourier expansions of ϕ and i. Clearly the mean values of $\Sigma\,\phi_A\,i_D$ and $\Sigma\,\phi_D\,i_A$ are zero, and hence the mean magnetic energy

T_m = mean value of t_m

$$= \frac{1}{2.10^8}[\Sigma\,\phi_D\,i_D + \text{mean value of } \Sigma\,\phi_A\,i_A]$$

Hence

$$\text{Mean value of } \frac{1}{10^8} \Sigma \phi_A i_A = 2 T_m - \frac{1}{10^8} \Sigma i_D \phi_D$$

The next term

$$\Sigma \frac{1}{C} \frac{d q_A}{dt} \int q_A dt.$$

Let

$$q = q_1 \sin (\omega t + \gamma_1) + q_2 \sin (2 \omega t + \gamma_2) + \ldots$$

Then

$$\frac{d q_A}{dt} = q_1 \omega \cos (\omega t + \gamma_1) + q_2 2 \omega \cos (2 \omega t + \gamma_2) + \ldots;$$

$$\int q_A dt = - q_1/\omega \cos (\omega t + \gamma_1) - \frac{q_2}{2 \omega} \cos (2 \omega t + \gamma_2)$$

Hence mean value of

$$\frac{d q_A}{dt} \int q_A dt = - \frac{q_1^2}{2} - \frac{q_2^2}{2} - \frac{q_3^2}{2} \ldots.$$

On the other hand mean value of

$$q_A^2 = + \frac{q_1^2}{2} + \frac{q_2^2}{2} + \frac{q_3^2}{2} + \ldots.$$

Hence mean value of

$$q_A^2 = - \text{ mean value of } \frac{d q_A}{dt} \int q_A dt.$$

The instantaneous electrostatic energy t_e is given by

$$t_e = \frac{1}{2} \Sigma \frac{q^2}{C} = \frac{1}{2} \Sigma \frac{(q_D + q_A)^2}{C}$$

$$= \frac{1}{2} \left[\Sigma \frac{q_D^2}{C} + \Sigma \frac{q_A^2}{C} + 2 \Sigma \frac{q_D q_A}{C} \right]$$

where q_D is the constant term in the Fourier expansion of q. Since mean value of

$$\Sigma \frac{q_D q_A}{C} = 0,$$

mean value of $t_e = T_e =$ mean value of

$$\frac{1}{2} \left[\Sigma \frac{q_D^2}{C} + \Sigma \frac{q_A^2}{C} \right]$$

Hence

$$\text{Mean value of } \Sigma \frac{1}{C} \frac{d q_A}{dt} \int q_A dt = 2 T_e - \Sigma \frac{q_D^2}{C}$$

Substituting into equation (**6**) we have finally

$$\Sigma \frac{\text{Reactive Power}}{\omega} + \frac{1}{10^8} \Sigma \phi_D i_D - \Sigma \frac{q_D^2}{C} = 2 (T_m - T_e)$$

The detailed steps in passing from $\Sigma \frac{\text{Reactive Power}}{\omega}$ taken for each branch to $\Sigma \frac{\text{Reactive Power}}{\omega}$ taken only for the terminals are fairly obvious and so were omitted in the above proof. There is one point however, which should be brought out in this connection, as it shows a limitation ruling out the homopolar machine from the relation. It will be readily seen that where slip rings are involved, all parts must be at the same potential, and the flux linkages between any point fixed on a ring and one of the brushes must be negligible. This last rules out the homopolar machine.

THE MILITARY ENGINEER

THE MILITARY ENGINEER, formerly PROFESSIONAL MEMOIRS, the Journal of the Society of American Military Engineers, has had its first issue. As successor of PROFESSIONAL MEMOIRS, which was published by the Corps of Engineers, U. S. Army, the new Journal aims to enter a much larger field and to operate on a larger scale than its predecessor. Its purpose as stated is to form a bond of union between all members of the engineering profession who are interested in the national defense to the end that the profession may render the maximum of service to the country in case of need. Toward this end an improved and very attractive bimonthly publication is issued, containing articles on both civil and military engineering. Some extracts from the editorial in the first number are interesting:

With this issue PROFESSIONAL MEMOIRS in a new form and under a new name enters a new era, on the occasion of its twelfth birthday. It must be an era of greater usefulness than that which has passed. We have a more important mission to perform, a larger clientele to whom we must appeal.

The scope of our efforts will be greatly increased. In this issue several new departments make their appearance and certain old ones have been abandoned. The news section, which now appears for the first time, is far from being complete or perfect. Still, we feel encouraged by a good beginning.

Our change of name is in accordance with our change of policy. A "memoir" is a solemn chronicle of a task well done. But a magazine such as ours, to fulfill the mission we have set before us, should not be a mere archive of technical data and methods. It must be a living thing, pulsating with human emotion and interest.

To be instructive a magazine should be entertaining. The journal of a scientific institute, the "proceedings" of a technical society, do not serve the same purpose as a current periodical. They are in effect archives of technical knowledge, and our journal is not such. Our "body politic" consists chiefly of live human interests and passions, men who are doing things, and not "book-worms," or animated encyclopedias of impractical ideas. We aim to dispense and distribute enthusiasm as well as knowledge. Enthusiasm and knowledge combined win many battles where either alone would fail.

The aim of this journal is to promote the practical efficiency the solidarity and the enthusiasm of the engineering profession, in the service of the country.

The dues for membership in the Society or for subscription to the journal are $4.50 per annum. The journal is published at Washington Barracks, D. C.

Regional Power Development and the Low Temperature Distillation of Coal

By C. M. GARLAND
Consulting Engineer, Chicago

FROM time to time, more or less practical and comprehensive schemes are suggested for the development of regional power plants for the distribution of cheap electrical power throughout industrial districts. It is an attractive subject and one that has been given considerable thought by power engineers and economists in general. The latest of these suggestions is that presented by Mr. W. S. Murray in an address before the Connecticut Chamber of Commerce, proposing a regional power development scheme to include the North Atlantic States, a reprint of which appeared in the January issue of this JOURNAL. Mr. Murray's address is in a measure the raison d'etre of the present article.

In the generation of power, the avoidable waste of fuel alone in the United States easily reaches the value of $1,500,000.00 a day, to which may be added the loss through the lack of continuity of service, decrease in production, and the loss through the purchase and maintenance of spare equipment.

The above are the avoidable losses under present methods of power generation in public utility and industrial plants as they stand today. Combine the savings which can be effected in these plants without even attempting larger scale methods of generation and distribution with the saving that can be effected through these methods and the total savings will amount to more than $3,000,000.00 a day. Mr. Murray's figures for the saving which may possibly be effected in the Atlantic Coast States are by no means exaggerated. The inefficiency in the industrial and also in most of the public utility plants is due to the poor design of the plant, to poor load factors and to poor operation. There is not one small or medium size plant in a hundred that is designed so that it can be operated efficiently or if it is so designed, is actually so operated.

All of the above conditions leading to poor economy in the use of fuel, to the waste of natural resources, to the losses enumerated above and to railroad and terminal congestion are traceable to small scale power and heat production and Mr. Murray's proposal would certainly ameliorate some of these conditions.

The writer is convinced, however, that no regional power development scheme north of the Mason and Dixon line which contemplates the generation of power from coal is complete unless it provides heat for industrial plants in winter, and furthermore, that no regional power development scheme contemplating the generation of power from bituminous or semi-bituminous coal is more than half-way complete if it does not contemplate the recovery of the by-products from the coal.

In the central and northern portions of the United States every industrial plant for from seven to eight months out of the year requires fuel for heating. In 75 per cent of these plants, the fuel required for heating is more than sufficient to generate the power required for manufacturing operations. For practical purposes, it may therefore be considered that the power is obtained during these months without fuel expenditure. This explains why only 30 per cent of the industrial plants buy their power. Of this 30 per cent 20 per cent would doubtless be better off if they had efficiently operated plants and generated their own power. The writer is a strong advocate of central station development but believes that it is well to recognize the limitations imposed by existant conditions.

The great barrier to Mr. Murray's project is therefore the fact that the average plant can take advantage of the increased economy of the central station only for four to five months out of the year. During the winter season the same amount of coal would have to be hauled to furnish heat insofar as the industrial plants are concerned. The amount of coal hauled would therefore be reduced only by the amount of coal saved by the electrification of the railroads which in this section would not amount to more than 20 per cent of the total. The writer therefore cannot see any great relief to railroad congestion unless some other method of heating, other than direct coal firing, is resorted to. It is also this coal for heating that leads to the over-crowding of railroad terminals during the winter months. Again, it is questionable if the poorer economy certain to result from the intermittent operation of boilers for the heating load in winter, assuming that the power load was taken by the central station, would not offset the saving effected through the electrification of the railroads. It is therefore quite certain that any regional power development that does not include also the distribution of heat will be extremely limited in its success, for with the present methods of electrical power generation, it would never be possible to distribute electrical current for the heating of large areas at low temperatures.

American inventive genius and American enterprise when working on projects in popular demand and when playing to the gallery, so to speak, transcends itself. When working on more obscure matters and on less popular projects it may be accused of groveling in the dust. An excellent illustration of this is the

comparison between the development of the automobile and the steam locomotive. The former having been developed in less than twenty-five years, taking its power from a source recognized as unreliable, operating on all kinds of roads and operated by unskilled mechanics is today just as reliable, requires less attention, has fewer repairs than the latter after over one hundred years of development, when operating on roads as smooth as engineering methods can produce, and when operated by skilled mechnanics with years of experience.

The same is true of the power station. The development of the electrical end, that end which is the most spectacular and appealing to the imagination of the public has been rapid. The steam and the fuel burning ends of the power plant have lagged behind. There has been no real development in the generation of steam or the burning of fuel in the past forty years. We are still burning most of our fuel on grates that were considered modern in the stone age and are absorbing heat in boilers representing zero in engineering achievement. So it is with the recovery of the by-products from coal. The amount of the by-products, the chemical composition and the methods of recovery have been known for years. Yet, the amount of by-products recovered from fuel burnt for the production of power is insignificant.

In the United States where at least 500,000,000 tons of bituminous coal are burnt annually, there are 10,000,000,000 gallons of tar and the equivalent of 30,000,000,000 pounds of ammonium sulphate, having a combined value of $2,500,000,000.00 burnt up with the coal. It is not practicable to save all of these by-products but a recovery of 25 per cent could reasonably be expected when it is considered that 80 per cent of the coal mined is used by industrial plants, public utility plants and the railroads.

The remarkable part of all of this is that the means are at hand today and have been at hand for a number of years, for carrying out the regional power development, the regional distribution of heat, the placing of every industrial load on the central station, the relieving of railroad congestion, particularly terminal congestion, through the reduction of the hauling of fuel, the reduction of the smoke nuisance in cities, and in addition to these, the recovery of the by-products from at least 25 per cent of the coal mined.

I refer to the combination of the well-known Mond by-product system of gas generation with the low temperature distillation of coal.

In the Mond process, coal is gasified in a special producer whereby the coal is converted into gas, tar and ammonia. The ammonia is recovered in the form of ammonium sulphate which amounts to from 50 to 100 pounds per ton of coal gasified and has a value of about four cents per pound under present prices. The value of this by-product therefore varies from $2.00 to $4.00 per ton of coal gasified, depending upon the amount recovered.

The tar recovered from the straight Mond process represents about 6 per cent of the weight of the coal and this tar consists principally of pitch which has little or no value.

The gas from the Mond process has a calorific value in the neighborhood of 140 B. t. u. per cubic foot and from 65 to 70 cubic feet of gas are obtained per pound of coal. This gas can be burnt under boilers with greater efficiency than the coal and without smoke It is also suitable for use in the firing of house heating boilers and for small or large industrial furnaces.

This gas can be piped economically within a radius of fifteen miles of the central station. This distance limits the size of the central station and to a certain degree, does not accomplish everything that could be desired from regional power and heat distribution. It does, however, relieve railroad terminal congestion and it will in a large measure, relieve main line congestion, due to the greater economy in the use of fuel and to the elimination of fuel hauled for the use of railroads.

The Mond process has been in use a great many years in Europe. At South Staffordshire, England, a plant has been in operation for a number of years which distributes gas and power to an industrial district of approximately 123 square miles. The Mond process is therefore a process that has been tried out and that is today operating on a commercial basis recovering the by-product of ammonium sulphate only.

By the low temperature distillation of coal is meant distillation of coal at a temperature around 1,000 deg. fahr. When distilling coals at this temperature, a very small amount of gas is generated of high calorific value and a large amount of tar with a small amount of ammonia.

This is a process which has been experimented with for years and which has been demonstrated on a practical scale by different investigators in this country and abroad. It has been definitely determined beyond question of a doubt that from 20 to 30 gallons of tar can be obtained from a ton of bituminous coal, something like 12 pounds of ammonium sulphate and from 1 to 2 cubic feet of gas and about 75 per cent of coke.

The tar from this process contains considerable quantities of motor fuel and creosotes. It has been estimated that it would be possible by the splitting up of this tar to obtain from 15 to 20 gallons of motor fuel per ton of coal. Investigations indicate that in a crude state this tar is worth in the neighborhood of 10 cents a gallon.

The coke from this process would probably contain in the neighborhood of from 12 per cent to 15 per cent of volatile matter which would contain most of the nitrogen originally in the coal. By gasifying this coke in the by-product gas producer, from 50 to 85 pounds of ammonium sulphate will be obtained per

ton of coke gasified and from 65 to 70 cubic feet of gas having a calorific value in the neighborhood of 140 B. t. u.

The low temperature process will yield by-products having a value of from $2.00 to $3.00 per ton of coal gasified. By gasifying the coke in the by-product gas producer the ammonia recovered will have a value of from $2.00 to $4.00 per ton of coal gasified, depending upon the amount recovered. In other words, by combining these two processes, by-products having a value of from $4.00 to $7.00 per ton of coal gasified may be obtained.

The low temperature distillation of coal can be carried out in cylindrical retorts and discharged into the producers. A combination of the two processes will result in a mixed gas having a calorific value of about 150 B. t. u. per cubic foot. There are other advantages in the combination of the processes such as the simplification of the scrubbing of the producer gas due to the fact that 95 per cent of the tar comes off in the low temperature distillation.

The market for the by-products obtained from these two processes is an ever increasing market which insures either a constant price or a constantly increasing price. A large portion of the tar by-product can be used for motor fuel. The market for ammonium sulphate as a fertilizer is ever increasing. The price of ammonium sulphate up to the time of the war has remained constant for years at about three cents per pound. At the present time, the price of this product is around four cents per pound.

In this combination of the low temperature process with the Mond gas producer lies the greatest development in the power field today and it is a development requiring practically no experimentation. All the parts constituting the plant have been worked out and all that is required is the assembling.

I would not ask Congress, as Mr. Murray has suggested, to appropriate $200,000.00 to find out if there was a $300,000,000.00 waste in the Atlantic Coast States for the same reason that I would not ask Congress to appropriate $200,000.00 to ascertain if the statue of Liberty is still standing in the New York Harbor. Every engineer experienced in power plant economy knows that this waste exists and has a comprehensive idea of the magnitude of this waste. I would, however, ask Congress for an appropriation of $5,000,000.00 for the construction of a workable sized plant along the lines of the combined Mond and low temperature distillation processes. This $5,000,000.00 properly used would bring greater returns to the American people than any money Congress ever spent.

THE AMERICAN-SCANDINAVIAN FOUNDATION

The American-Scandinavian Foundation, acting upon nominations made by colleges of this country, has awarded to American students 20 traveling fellowships for study in Denmark, Norway and Sweden during the academic year 1920-1921. More than 150 application papers were considered by the committee of college professors and technological experts who made the selection of 19 of the 20 Fellows. The twentieth will be appointed later with the assistance of C. F. Marvin, Chief of the U. S. Weather Bureau, as this Fellow will be sent to study oceanography and weather forecasting at the Bergen Geo-Physical Institute, Norway. The candidates represented most of the larger American colleges, and among the Fellows and alternates appointed are students from either coast, from Harvard and Columbia, and also from the Universities of California and Oregon, and from the Universities of Illinois, Nebraska and Texas. Ten of the Fellows are appointed for study in Sweden, and five each for study in Denmark and Norway. Those who go to Sweden this year will study forestry, chemistry, physics, hydro-electrical engineering, social economy or Indic philology; in Norway they will study physics, hydro-electrical engineering, oceanography, literature, or social sciences; in Denmark, bacteriology, physiology, industrial organization, literature or music. Among those to whom Fellowships were awarded are three women, Mrs. Elizabeth P. Hunt of Bryn Mawr, Miss Helen A. Purdy of Columbia, and Miss Hanna A. Larsen, translator of Jacobsen's Marie Grubbe and Niels Lyhne. The Fellows will sail from New York in late spring or early summer, and will spend the summer in traveling about in the countries to which they are appointed, familiarizing themselves with the language and will begin study at Scandinavian institutions in the fall. These Fellowships are awarded annually and are part of an international exchange which provided also for 20 Swedish, Danish and Norwegian students at American colleges. The funds for the fellowships were pledged by Americans and Scandinavians desirous of promoting friendly relations and intellectual interchange between the countries of northern Europe and the United States.

TRADE MARK CONVENTION RATIFIED

The Buenos Aires Trade Mark Convention has been ratified by the Senate and House conferees. Changes in the conference were of a minor nature. A provision was added stating that trade marks of sufficient similarity to previous trademarks as to cause confusion and mistakes in the mind of the public or to deceive purchasers are not to be registered. A new section was added by the conferees, which will protect the rights of the American trade in foreign countries. It applies to other countries as well as to South America.

Theory of Speed and Power Factor Control of Large Induction Motors by Neutralized Polyphase Alternating Current Commutator Machines

BY JOHN I. HULL

Designing Engineer, General Electric Co., Schenectady, N. Y.

Theory of induction motor control, discussing single-range (below synchronism only) speed and power factor control by means of a constant-speed series commutator motor, by means of a constant-speed shunt commutator motor, by means of a constant-speed compound excited commutator motor; double-range (all speeds above or below synchronism) speed and power factor control by means of a constant-speed shunt commutator motor; and double-range (either above or below synchronism) operation remote from synchronism. The discussion is illustrated in detail, special attention being paid to the circle diagram.

A STATIONARY polyphase wound-rotor induction motor is merely a static transformer arranged so that the primary coils are all on one part of the magnetic circuit, and the secondary coils on another part of the magnetic circuit, the two parts thus being arranged so as to permit relative motion. The reluctance of the magnetic circuit is kept as low as possible by imbedding both primary and secondary winding in slots, thereby permitting the "teeth" between the slots of the primary iron to come as close to the "teeth" of the secondary iron as safe mechanical clearance permits. The necessity of some clearance or "air gap" makes the reluctance, hence, the magnetizing current and kv-a. larger than for the static transformer of similar capacity, voltage and frequency, while the separation of the primary winding from the secondary winding and the imbedding of both in slots make the leakage reactances larger than for the corresponding static transformer. It is thus evident that the induction motor may logically be considered from the point of view of a transformer so arranged as to permit the forces set up in the secondary conductors to cause rotation, at the cost of an increase in the magnetizing current and the leakage reactance.

The flux common to both and set up by the resultant of the primary and secondary magnetomotive forces is the link of mutual influence between the primary and secondary. This influence manifests itself as electromotive forces set up in proportion to the effective number of turns, the flux, and the frequency in the circuit in question. (Of course, this is rigorously true only with the usual assumptions of sine wave distribution, etc.)

The torque is proportional to the summation of the products of the secondary turns, and the components of current in phase with the common flux of each, and to the common flux.

The usual theory of the induction motor takes into account only the phenomena within the motor itself, performance with adjustable external secondary resistance being analyzed by considering it to be merely an addition to the normal resistance of the secondary.

In Fig. 1, we reproduce a circle diagram, a vector diagram for analyzing induction motor performance, which lends itself to the introduction of electromotive forces etc., of concatenated machines.

$A H = I_1$ (proportional to primary current) represents the flux linking primary and secondary which would be produced by the primary current alone. (Saturation neglected)

$H I = C_1 I_1$ represents primary leakage flux.

$H G = I E = I_2$ (proportional to the secondary current) represents the flux linking secondary and primary which would be produced by the secondary current alone. (Saturation neglected)

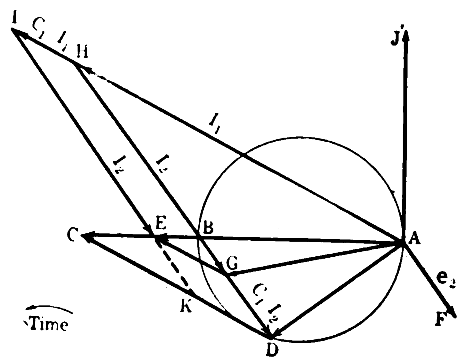

FIG. 1—THE CIRCLE DIAGRAM OF AN INDUCTION MOTOR

$G D = C_2 I_2$ represents secondary leakage flux.

$A E$ is thus the resultant of all the primary flux and that secondary flux, linking the primary, so that neglecting primary resistance drop, E is a fixed point for constant line voltage and frequency, as $A E$ is the flux which generates the counter e. m. f. to balance the applied voltage e_1.

$H G$ intersects $A E$ at B, and as

$$A B / A E = \frac{I_1}{I_1 (1 + c_1)},$$

we see that $A B$ is constant, making B also a fixed point. $A D$ is resultant of I_1 and $I_2 + C_2 I_2$ and therefore generates all secondary electromotive forces ex-

To be presented at the Annual Convention of the A. I. E. E., June 29–July 2, 1920.

cept resistance drop, which is, therefore in phase opposition to the voltage e_2, set up in the secondary in quadrature to flux $A D$. This makes $A F$ parallel to $H D$ and to $I E$ and further makes $A D H$ a right angle, which taken in connection with the fact that, as shown above, A and B are fixed points, demonstrates that the curve traced by point D is the arc of a circle.

A line parallel to $A I$ from point D intersects prolongation of $A E$ at C and prolongation of $I E$ at K.

$$\underline{C D} = C K + K D$$

$$\frac{C K}{E K} = \frac{A I}{I E}$$

$$C K = \frac{C_2 I_2 \times I_1 (1 + C_1)}{I_2} = I_1 C_2 (1 + C_1)$$

$K D = H I = C_1 I_1$ (since they are parallels intercepted by parallels)

$$\underline{C D} = I_1 [C_1 + C_2 (1 + C_1)]$$

$$\underline{B D} = B G + G D$$

$$\frac{B G}{E G} = \frac{I E}{I A}$$

$$B G = \frac{E G \times I E}{I A} = C_1 I_1 \times \frac{I_2}{I_1 (1 + c_1)} = I_2 \times \frac{C_1}{1 + C_1}$$

$$G D = C_2 I_2$$

$$\underline{B D} = I_2 \left(C_2 + \frac{C_1}{1 + C_1} \right) = \frac{I_2}{1 + C_1} \times (C_1 + C_2 (1 + C_1)$$

$E A$ is the flux whose counter e. m. f. balances all the applied line voltage as noted above. Let it be designated I_m. $B A$ is the *mutual flux* at running light and, if denoted by I_0, we have $I_0 = \frac{C_1}{1 + C_1}$.

$$C B = C E + E B$$

$$\frac{C E}{E A} = \frac{E K}{E I}$$

$$C E = E A \times \frac{E K}{E I} = I_m \times \frac{C_2 I_2}{I_2} = I_m C_2$$

$$\frac{E B}{E A} = \frac{I H}{I A} \qquad E B = I_m \times \frac{C_1 I_1}{I_1 (1 + C_1)} = I_m \times \frac{C_1}{1 + C_1}$$

$$C B = I_m \left(C_2 + \frac{C_1}{1 + C_1} \right) = \frac{I_m}{1 + C_1} \times [C_1 + C_2 (1 + C_1)] = I_0 [C_1 + C_2 (1 + C_1)]$$

Further, C is a fixed point since:

$$\frac{C E}{E A} = \frac{E K}{E I} = \text{Constant} = C_2 \times I_2 / I_2$$

$$C A = E A + C E = I_m + I_m C_2 = I_m (1 + C_2) = \frac{I_m (1 + C_2) [C_1 + C_2 (1 + C_1)]}{C_1 + C_2 (1 + C_1)}$$

Summing up we have:

$$C D = I_1 [C_1 + C_2 (1 + C_1)]$$

$$D B = \frac{I_2}{1 + C_1} \times [C_1 + C_2 (1 + C_1)]$$

$$C B = \frac{I_m}{1 + C_1} \times [C_1 + C_2 (1 + C_1)] = I_0 [C_1 + C_2 (1 + C_1)]$$

$$C A = \frac{I_m (1 + C_2)}{C_1 + C_2 (1 + C_1)} \times [C_1 + C_2 (1 + C_1)]$$

$$E A = I_m$$

$$B A = I_0$$

With proper scale, I_m could be made to represent the magnetizing current for a total flux I_m, (which is the quantity commonly calculated, as the primary reactance and resistance drop are usually omitted) I_0 could be made to represent the true running light current, primary reactance drop considered, I_1 the primary current and I_2 the secondary current. If we now change the scale of the diagram by the factor $C_1 + C_2 (1 + C_1)$, we may say that magnetizing i_m divided by $1 + C_1$ equals $C B$, equals true running light current i_0; primary current i_1 equals $C D$; secondary current divided by $1 + C_1$ equals $D B$.

A standstill, with zero secondary resistance $A D$, the resultant secondary flux must, of course, be zero, as its generated voltage is zero, which means that D coincides with A and $C D = C A$, so that we have the ideal short-circuit or standstill current with zero secondary resistance equal to $C A$.

As $C_1 I_1$ is defined as primary leakage flux, the primary reactance drop with current i_m is $C_1 e_1$, since i_m produces a total flux whose e. m. f. is equal to e_1. The primary reactance drop is further equal to $i_m X_1$ if X_1 be the primary reactance, thus:

$$C_1 e_1 = i_m X_1$$

$$C_1 = \frac{i_m X_1}{e_1}, \text{ and similarly,}$$

$$C_2 = \frac{i_m X_2}{e_1}$$

Thus, to draw the diagram of the motor, we need to know the primary and secondary reactances X_1 and X_2 and the nominal magnetizing current i_m. We need then only so much of Fig. 1 as is shown in Fig. 2.

Having chosen a scale, lay off:

$C B$ equal to i_m

$$C A \text{ equal to } \frac{i_m (1 + C_2)}{C_1 + C_2 (1 + C_1)} \text{ and}$$

draw a circle with $B A$ as diameter. $C M$ is the in phase or watt component of input current for any considered load. $M D$ parallel to $C A$ then locates D and the remainder of the diagram. The primary current is then $i_1 = C D$ and the secondary current i_2 is then $(1 + C_1) D B$, or if we use as the unit for i_2 the unit denoting the other currents divided by $1 + C_1$, we can let $D B = i_2$.

To find the secondary voltage $e_2 = A F$, we can first determine its value reduced to full frequency. The voltage generated by flux $A E$ of Fig. 1 is e_1, and that generated by $A B$ is, therefore, $\frac{e_1}{1 + C_1}$. So in Fig. 2, knowing e_1, we can say that $A B$ units of

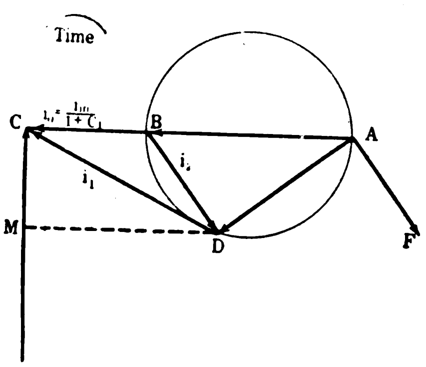

Fig. 2—Simplified Diagram

length correspond to $\frac{e_1}{1 + C_1}$ volts, and can regard $A B$ etc. as measures of voltage. So $A D$ is $\frac{A D}{A B}$ times $\frac{e_1}{1 + C_1}$ volts at standstill frequency. If the secondary resistance is known, the actual value of secondary induced voltage e_2 is, of course, $i_2 r_2$, so that per cent slip is $s = \frac{i_2 r_2}{A D}$.

"Synchronous watts" torque is $B D$ times $A D$, output is $(1 - S) B D \times A D$, efficiency $(1 - S) B D \times \frac{A D}{e_1} M C$, power factor $\frac{M C}{C D}$

If the ratio of secondary turns to primary turns is other than 1 to 1, the diagram is, of course, of necessity drawn for all factors reduced to either primary or secondary terms, secondary terms being usually used for work of the present sort. Thus, the primary voltage to be expressed in terms of secondary must, of course, be multiplied by ratio of secondary to primary effective terms, primary reactance by the square of this ratio, etc.

In the demonstration of Figs. 1 and 2, it was pointed out that point D traces the arc of a circle whose diameter is $B A$, because $A D B$ is a right angle, due to the phase opposition of e_2 and $i_2 r_2$ when the only e. m. f. in the secondary circuit, other than that induced by the total secondary flux, is resistance drop. If, as in Fig. 3, another e. m. f. than the resistance drop as

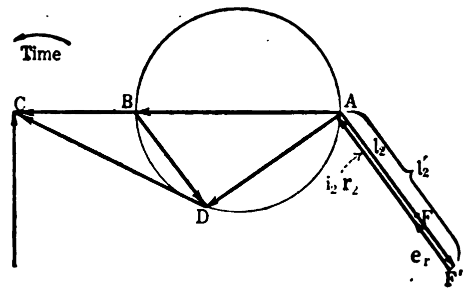

Fig. 3—Induction Motor Diagram
With regulating voltage e_r introduced into secondary in phase opposition with total induced e. m. f.

e_r be introduced, then D will still trace the circle with the diameter $A B$ when and only when the introduced e. m. f. is in phase with or in phase opposition to e_2. In this case, for given values of i_1, i_2 etc., e_2 must be equal and opposite to the algebraic sum of $i_2 r_2$ and the introduced voltage; hence, since the inducing flux of e_2 is determined by the currents,—its inducing frequency and the slip and speed must follow variations in the algebraic sum of $i_2 r_2$ and the introduced voltage.

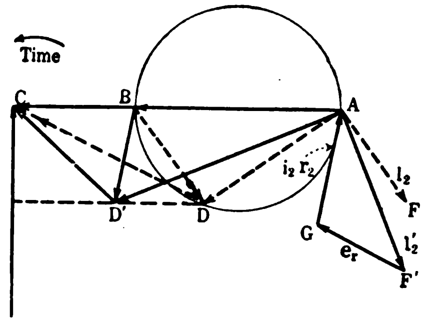

Fig. 4—Induction Motor Diagram
With regulating voltage e_r introduced into secondary out of phase with total induced e. m. f.

It is, therefore, evident that varying the introduced voltage, while maintaining it in phase with e_2 gives a means of varying the speed of the motor without effecting its power factor torque etc.

If now, as in Fig. 4, the introduced e. m. f., e_r be of different phase from that of e_2, point D departs from the circumference of the circle whose diameter is $B A$, as shown at D^1 because i_2 is no longer in phase opposition to e_2, hence, $A D^1 B$ is no longer a right angle. It is seen that in addition to regulating the speed, the power factor of the motor may also be

regulated by proper selection of phase as well as magnitude of the introduced e. m. f.

It is clear, of course, that the frequency of the introduced or regulating e. m. f. must at all times be exactly that of e_2, in order to maintain the phase relation shown.

Thus, if we can introduce at exact secondary frequency a regulating voltage of controllable phase

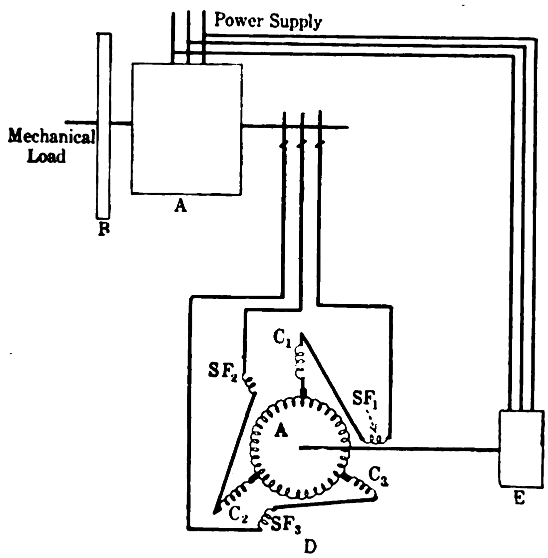

Fig. 5—Neutralized Series-Excited Three-Phase A-C. Commutator Machine and Connections for Automatic Single-Range Regulation of Induction Motor Equipped with Flywheel to Reduce Peaks on Line

with respect to e_2 and controllable magnitude, we shall be able to regulate either speed, power factor or both.

Single-Range, (Below Synchronism Only) Speed and Power Factor Control by Means of a Constant-Speed, Series Commutator Motor

In Fig. 5, we show schematically at D, a three-phase series neutralized commutator machine whose terminals are connected to the secondary slip rings of main motor A. The speed of D is held practically constant by generator E.

Neutralizing winding C_1, C_2, C_3 balances the armature reaction (magnetomotive forces) of armature A, and so of necessity neutralizes the e. m. fs. set up in A by the transformer action of the fluxes induced by series exciting windings $S\,F_1$, $S\,F_2$, $S\,F_3$. (C_1, C_2, C_3 being in series with A carry the same currents as A, hence, for a balanced condition of magnetomotive forces must have an equivalent and opposite number of turns, so the e. m. fs. also cancel). Thus the e. m. fs. appearing at the terminals of D are the leakage reactance drop, resistance drop and the rotation e. m. f. induced by the rotation of the armature A. The rotation e. m. f. is, of course, proportional to the flux and the speed of rotation, the flux, neglecting saturation being proportional to the main currents which flow through series exciting windings $S\,F_1$, $S\,F_2$, $S\,F_3$. This arrangement can then be seen to be such that the speed of A will be reduced with the increase of load, provided the rotation voltage, as e_r in Figs. 3 and 4, be given a suitable component in phase with the resistance drop, thereby having the same effect on the main motor speed, as increasing the resistance.

Up to the point of the magnetic saturation, two laws may be seen to inhere in the machine D.

1. The flux, hence, the rotation voltage at constant speed, is proportional to the current.

2. The phase angle between the current and the rotation voltage (hence, the angle between resistance drop and rotation voltage) is constant, (it can only be changed by changing the construction of the machine).

These are the basis of the circle diagram of Fig. 6:

Points A, B and C are determined exactly as in Fig. 1, except that for X_2 we now substitute X_{2+c+c_s} where $X_{2+c+c_s} = X_2 + X_c + X_{c_s}$ and X_c = leakage reactance of regulating motor at primary frequency

$$X_{c_s} = \frac{\text{kv-a. required to excite regulating motor}}{i_2^2 \times \sqrt{3}}$$

The kv-a. is at primary frequency and unsaturated iron of regulating motor is assumed. Obviously the performance of an induction motor is not changed for our purposes, having a part or all of the rotor leakage

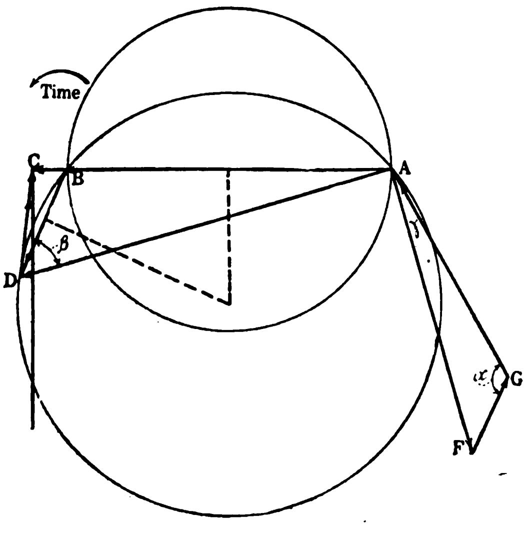

Fig. 6—Circle Diagram of Induction Motor with Constant-Speed Series Commutator Regulating Machine

reactance external to the machine. Angle $\alpha = F\,G\,A$, between resistance drop $F\,G$ and rotation e. m. f. $G\,A$ is constant by law No. 2, and $G\,A$ is by law No. 1 proportional to $B\,D$ and hence to $F\,G$. For these reasons angle $G\,F\,A$ is constant and since angle $B\,D\,A = 90$ deg. $-$ angle $G\,F\,A$, we see that β = angle $B\,D\,A$ is also constant.

Thus, as A, B, and C are fixed points, point D traces a circle whose center must be at the intersection of the perpendicular bisectors of $A\,B$ and $B\,D$.

We have remarked that Figs. 1, 2, 3, 4 and 6 are

rigorous when and only when the iron of the machine is unsaturated, that is, when the flux may be regarded as proportional to the ampere turns. This condition is closely enough approximated in the main induction motor so that saturation may be neglected without much loss of accuracy. For the series machine of Fig. 6, however, to be of economical proportions, considerable saturation will be attained within the working range; hence, it becomes desirable to investigate its effects. In Fig. 7, A, B, C has been determined as was done for Fig. 6, and $B\,D\,A$ is the corresponding circle determined by angle $B\,D\,A$, which is determined by ratio $\frac{A\,G}{F\,G}$ and design angle α, saturation neglected.

Now with current $B\,D$, we can calculate a new value

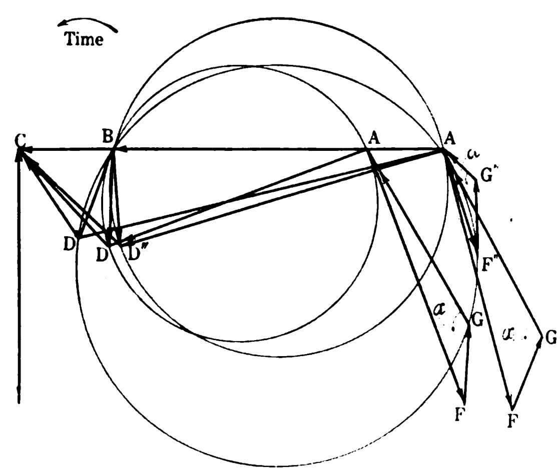

FIG. 7—DIAGRAM OF INDUCTION MOTOR AND CONSTANT-SPEED SERIES COMMUTATOR REGULATING MACHINE

Taking account of saturation of iron of regulating machine.

for X_{2+c+c_s} which will hold only for this one current, since in expression

$$X_{c_s} = \frac{\text{kv-a. to excite regulating motor}}{i_2^2 \times \sqrt{3}}$$

we can determine kv-a. (at full frequency, of course) from the known or assumed magnetizing curve of the regulating machine. With this new (and decreased) value of X_{2+c+c_s} we calculate $A^1\,C$ instead of $A\,C$. If the new value of X_{2+c+c_s} were constant, our new circle would be $B\,D^1\,A^1$, but as it varies, D^1 may be the only load point upon it. Triangle A^1, F^1, G^1 is, of course, equal to triangle $A\,F\,G$, and angle $B\,D^1\,A^1$ is equal to angle $B\,D\,A$.

A second effect of the saturation is that the ratio of rotation e. m. f. to field current (field current being the same as the main current for a series machine) is reduced, so considering this, $A^1\,G''\,F''$ is the e. m. f. triangle with angle $A^1\,G''\,F''$ still equal to angle $A\,G^1\,F^1$ and $A\,G\,F$.

Since $A^1\,G''$ is less than $A^1\,G^1$ and $G''\,F'' = G^1\,F^1$ with constant α we see that angle $G''\,F''\,A^1$ is less than angle $G^1\,F^1\,A^1$, hence, angle $B\,D''\,A^1$ greater than angle $B\,D^1\,A^1$ and the circle if X_{2+c+c_s} and $\frac{A\,G''}{G''\,F''}$ were constant would be $B\,D''\,A^1$.

We thus see that the two effects of saturation of the regulating machine partially offset one another, as the reduction of X_{2+c+c_s} makes the imaginary circle larger and the power factor more leading, while the reduction of ratio $\frac{A^1\,G^1}{G^1\,F^1}$ to $\frac{A^1\,G''}{G''\,F''}$ makes the imaginary circle smaller and the power factor more lagging.

The point D'' cannot be located by rule and compass unless we calculate triangles $A^1\,D''\,B$ and $A^1\,F''\,G''$ which can be done as follows:

$A^1\,G''$, $G''\,F''$ and angle $A^1\,G''\,F''$ are known.

$$A^1\,F'' = \sqrt{\overline{A^1\,G''}^2 + \overline{G''\,F''}^2 - 2 \times A^1\,G'' \times G''\,F'' \times \cos A^1\,G''\,F''}$$

$$\operatorname{Sin} A^1\,F''\,G'' = \frac{A^1\,G'' \times \sin A^1\,G''\,F''}{A^1\,D''}$$

Angle $F''\,A^1\,G''$

$$= 180\text{ deg.} - (\text{angle } A^1\,F''\,G'' + A^1\,G''\,F'')$$

determining triangle $A^1\,F''\,G''$.

In triangle $B\,D''\,A^1$, $B\,A^1$ and $B\,D''$ are known and angle $B\,D''\,A^1 = 90$ deg. $-$ angle $A^1\,F''\,G''$.

$$\operatorname{Sin} B\,A^1\,D'' = \frac{B\,D'' \times \sin B\,D''\,A^1}{B\,A^1}$$

Angle $D''\,B\,A^1$

$$= 180\text{ deg.} - (\text{angle } B\,A^1\,D'' + \text{angle } B\,D''\,A^1)$$

$$A^1\,D'' = \frac{B\,D'' \times \sin D''\,B\,A^1}{\sin B\,A^1\,D''} \quad \text{or} \quad \frac{A^1\,B \sin D''\,B\,A^1}{\sin B\,D''\,A^1}$$

Knowing, thus, $A\,D''$ and $B\,D''$, we can find point D'' with compass.

We can now construct the curve traced by D'' by assuming values of current $B\,D''$, calculating for each value $A^1\,B$, $A^1\,G''$ and $A^1\,D''$ as described.

For the designs ordinarily encountered, this yields a curve so closely approximating for the working load the original circle $B\,D\,A$ in which saturation is neglected, that it is not necessary to go beyond the construction of $B\,D\,A$ to get a good idea of the characteristics except slip which is $\frac{A^1\,F''}{A^1\,D''}$. If the scale used for $A^1\,F''$ is not that of $A^1\,D''$, then, of course, slip is $\frac{A^1\,F''}{A^1\,D''}$ multiplied by the proper ratio of scales.

The combination in Fig. 5 is suitable to service in which there are rapid and wide fluctuations in load which it is desired to absorb as much as possible by the flywheel B. This arrangement is superior to the use of a resistance across the slip rings because instead of being wasted as in the resistance, the slip energy

can all be returned to the power system except for the machine losses of D and E. When applied to a motor with secondary resistance the flywheel reduces the peak loads by delivering torque as it is retarded. The return of most of the slip energy to the line by the regulating set decreases the peak loads still more. A further advantage for the regulating set is the means which it affords of materially improving the power factor of the main motor.

Single-Range (Below Synchronism Only), Speed and Power Factor Control by Means of a Constant-Speed, Shunt Commutator Motor

The series regulating set is, of course, the simplest form, but it is not adjustable without tapping the field winding or external apparatus, and as it imparts to the main motor the characteristic of a material reduction of speed with the assumption of load, it is not suited to the majority of industrial uses in which variable speed from large induction motors is required. In the greater number of cases, it is desired to adjust the speed to a value suited to the momentary requirement of the process, and have the speed remain at approximately the adjusted value irrespective of load variation.

The total induced secondary e. m. f. of an induction motor including the secondary reactance drop is proportional to the "rotor field" (See A D of Fig. 1) and the slip. So, as is well appreciated, within the working range the slip is about proportional to the torque as the torque is about proportional to the rotor current, the current being proportional to the total induced rotor voltage. If at a given load we obtain speed reduction by an increase in resistance or by the use of a "series" regulating set, in which cases an increase in secondary induced e. m. f., hence, slip is required to overcome the additional resistance drop, or the rotational e. m. f. of regulating set, plus resistance drop, then, as soon as the load disappears, the main motor speeds up to synchronism, since the secondary resistance drop and the rotational e. m. f. of the regulating motor vanish with the current. If the rotational e. m. f. of the regulating motor could be made independent of the load and of the slip, then with the departure of load it would remain constant, so that the speed would only rise enough to make the total induced secondary e. m. f. equal to the rotational voltage of the regulating motor, leaving no resultant to circulate load current. With load fluctuations, the speed would then fluctuate by only such small amounts as to cause at all times the small difference between total induced secondary e. m. f. and the rotational e. m. f. of the regulating motor to overcome the small resistance drop of the windings; usually only a few per cent of synchronous speed.

In Fig. 8 is shown an arrangement to approximate these conditions. "A" is the main motor, "D" a neutralized three-phase shunt commutator motor, whose speed is held practically constant by generator E, returning the energy derived from D to the line. "B" is an auto transformer excited from the slip ring circuit and provided with suitable taps to apply predetermined percentages of the slip ring e. m. f. to the shunt exciting windings F_1, F_2, F_3. Assume that the resistance drop in the F_1, F_2, F_3 circuit is negligible and that "B" applies to F_1, F_2, F_3 the selected percentage of the total secondary induced e. m. f. This with the further assumption that the reactance drop of the regulating motor is included in the slip ring e. m. f. (which is supplied to "B") and that the resistance drop of the main motor rotor is not included in the slip ring e. m. f., will give what may be termed for our purposes, "pure shunt excitation." The effects of

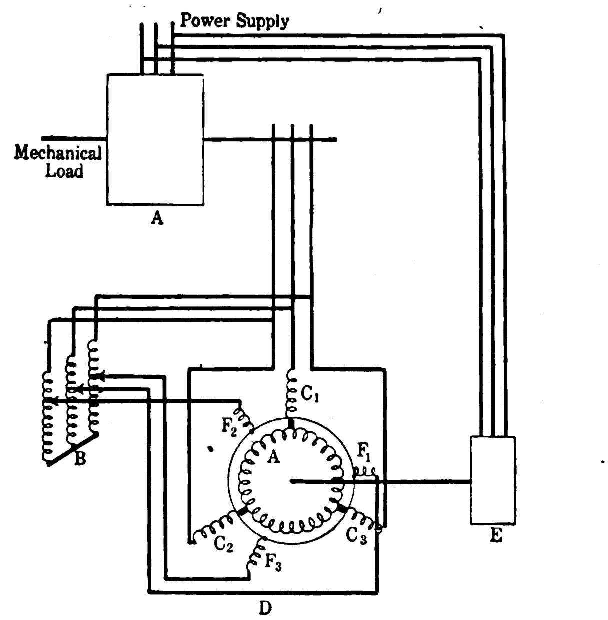

Fig. 8—Neutralized Three-Phase Shunt Constant-Speed A-C. Commutator Machine and Connections for Adjustable-Speed Control of Induction Motor below Synchronism

these assumptions will be pointed out later. The counter e. m. f. of F_1, F_2, F_3 thus consists of the e. m. f. set up by the flux excited by it, and is, therefore, proportional to the flux and the frequency (frequency itself being proportional to slip s).

$$i.\,e.,\quad e_f = k \times \phi \times s$$

The e. m. f. applied to the field is proportional to the total induced e. m. f., as remarked above, and the total induced e. m. f. is equal to its own standstill value for the main motor current (hence torque) in question times the slip, so we see that,

total induced e. m. f. at standstill $\times\, s = k \times \phi \times s$.

ϕ is thus independent of frequency and proportional only to total standstill induced e. m. f. Referring to Fig. 9, A, B, C is constructed exactly as Fig. 1, including the leakage reactance of the regulating motor with that of the secondary of the main motor, so that instead of X_2, we shall have $X_{2+c} = X_2 + X_c$ and

instead of C_2, we shall have C_{2+c}. The circle B, D, A would thus apply with regulating set D and E of Fig. 8, stationary. With the regulating set running, we get secondary current $B\,D^1$, total induced e. m. f., $A\,F$ of main motor secondary proportional to slip and to $A\,D^1$ and rotation e. m. f. of regulating motor $A\,G$ proportional to $A\,D^1$ and at a constant angle γ from $A\,F$, angle γ being determined by the connections of the transformer B and exciting winding F_1, F_2, F_3 of Fig. 8.

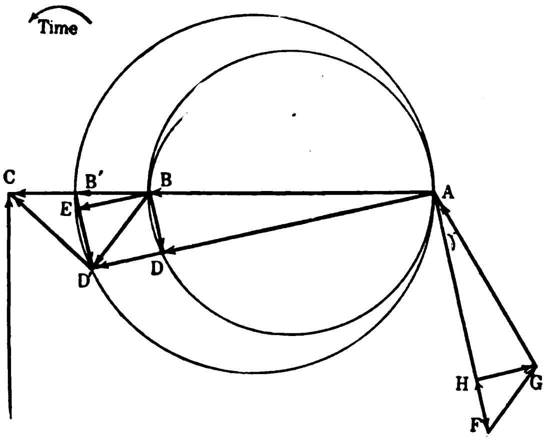

Fig. 9—Circle Diagram of Induction Motor and Pure Shunt Excited Constant-Speed Commutator Machine

Resolve resistance drop $F\,G$ into the component $F\,H$ in phase opposition to $A\,F$ and $H\,G$ in quadrature to $A\,F$, the corresponding components of secondary current $B\,D^1$ being $B\,D$ and $D\,D^1$.

$D\,D^1$ is proportional to $H\,G$, $H\,G = A\,G \sin \gamma$, so $H\,G$ is proportional to $A\,G$ (γ constant) which is proportional to $A\,D^1$, hence, $D\,D^1$ is proportional to $A\,D^1$.

$A\,D = A\,D^1 - D\,D^1$, hence, $A\,D$ is proportional to $A\,D^1$.

$B\,D$ and $B^1\,D^1$ are both perpendicular to $A\,D^1$, hence,

$\dfrac{A\,B^1}{A\,B} = \dfrac{A\,D^1}{A\,D}$ = constant, and B^1 is fixed point.

So curve traced by D^1 is a circle.

Slip "s" is equal to $\dfrac{A\,F}{A\,D^1}$.

At running light (zero torque) $B\,D$ and $H\,F$ become zero. (For proof of this see Fig. 1. The torque of the motor is proportional to the mutual flux $A\,G$ and the component of secondary current in quadrature with it. This is the same thing as the total secondary current and the component of the mutual flux in quadrature to the current, which component is equal to $A\,D$, the "rotor field." The torque is, therefore, zero when $B\,D$ is zero, and in Fig. 9, $B\,D$ is the torqe producing component of $B\,D^1$.)

Thus, running light slip $s_0 = \dfrac{A\,H}{A\,D^1}$, and the additional slip s_1, due to the load is thus, $\dfrac{H\,F}{A\,D^1}$.

It is thus seen that at running light the main motor runs at slip s_0, determined by the angle γ, and the ratio $\dfrac{A\,G}{A\,D^1}$, which conditions are adjusted by the connections at B, Fig. 8. The load slip s_1 is the same for all values of s_0, provided angle γ be so chosen that $\dfrac{H\,G}{A\,D^1}$ remains constant, and is the same as would obtain for a normal motor whose circle is $B^1\,D^1\,A$ and whose short-circuited secondary has the resistance corresponding to the current $B^1\,D^1$ and the drop $H\,F$. Thus it is evident that the main motor, regulated as in Figs. 8 and 9 would retain practically the same load slip-torque, power factor-torque and input-torque characteristics as with short-circuited slip rings, but would have no-load speeds equal to the synchronous speed $\times \dfrac{1 - s_0}{1}$.

It will be noted from Fig. 9 that the primary power factor can readily be improved and that at the same time the pull-out torque of the main motor can be increased.

Single-Range (Below Synchronism Only) Speed and Power Factor Control by Means of a Constant Speed, Compound Excited Commutator Motor

Occasionally, in processes where the peak loads are high and of brief duration and of sufficient magnitude

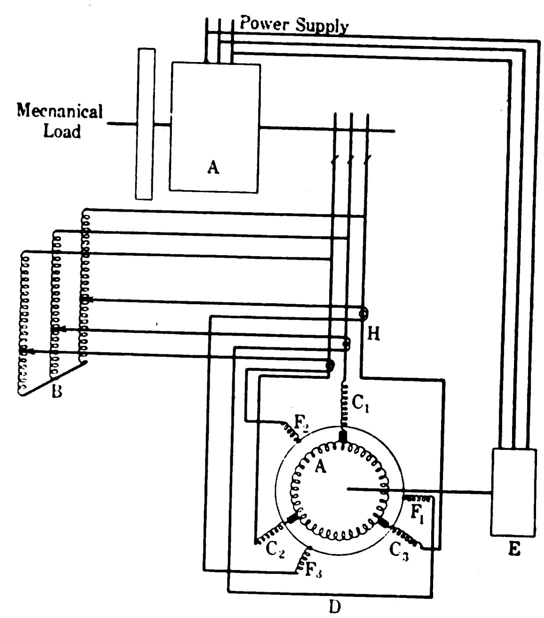

Fig. 10—Neutralized Compound-Excited Constant-Speed Three-Phase A-C. Commutator and Connection for Adjustable-Speed Single-Range Speed Control of Induction Motor Giving Automatic Drop in Speed With Increase of Load.

in proportion to the capacity of the supply system to be objectionable, it becomes desirable to have a larger drop in speed due to load than would be obtained with a shunt commutator motor, so that a fly-wheel can be

effectively added to smooth out the peak loads, and at the same time retain the adjustability of the speed. Fig. 10 illustrates a method of compounding the regulating motor.

In the shunt excitation, neglect the same factors as in the case of the shunt regulating motor, (the secondary resistance drop of the main motor and the absence of the reactance drop of the regulating motor). In order to get the compounding action it would not do merely to put in some series turns as in a d-c. machine, since there is applied to the shunt field a fixed percentage of the total induced secondary e. m. f., which means a flux proportional to the rotor field of the main motor as already pointed out. Thus, the ampere turns of the

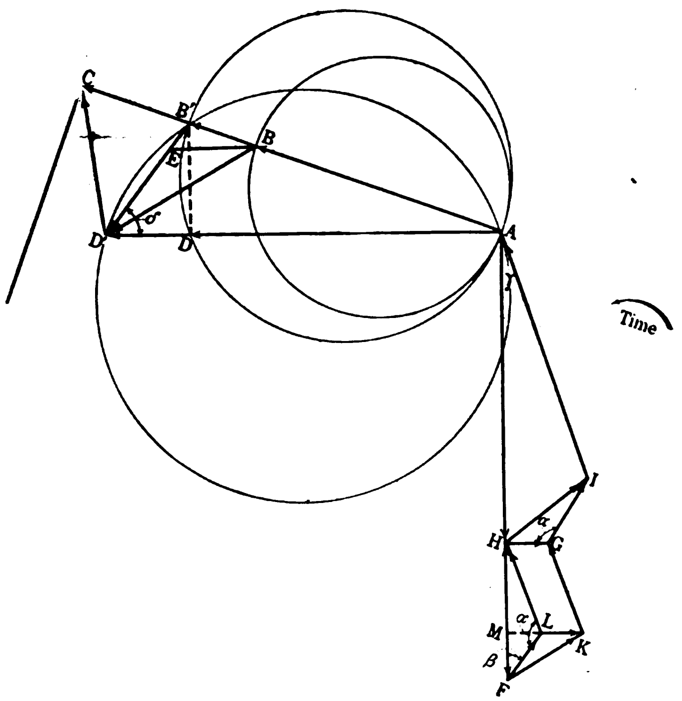

FIG. 11—CIRCLE DIAGRAM OF INDUCTION MOTOR WITH COMPOUND-EXCITED CONSTANT-SPEED A-C. COMMUTATOR REGULATING MACHINE

series winding would merely be balanced by a change in the shunt current, F_1, F_2, F_3 serving as the primary of a transformer. It, therefore, becomes necessary to change the field voltage in response to load, in order to change the flux and hence the rotation e. m. f. This is done by the series transformer H, which has an air gap in the magnetic circuit, so that its flux is proportional to the resultant of the primary and secondary ampere turns. Of course, a proportionate effect upon the flux of the regulating motor, will accompany any changes in the flux in the series transformer (slip transformer) since the alteration in flux produces a proportionate alteration in voltage applied to regulating motor field, and this in turn a proportionate change in flux thereof. This then means that the rotation e. m. f. will contain a component proportional to the resultant ampere turns of the series transformer, which component, of course, may itself be resolved into components corresponding to the components of the resultant ampere turns of the series transformer.

The performance of the motor, controlled as shown in Fig. 10, is illustrated in Fig. 11, in which A, B and C are again found as for Fig. 1, including the reactance of machine D with that of the secondary of A. B is the no-load point, such that $B\,B^1$ is the no-load secondary current, and D^1 is the load point under consideration. Resolve secondary current $B\,D^1$ into component $B\,E$ parallel to $A\,D^1$ and $E\,D^1$ part of $B^1\,D^1$. Component $B\,E$ produces no torque. $I\,A$ is the rotational e. m. f. of regulating motor at constant angle from total induced secondary e. m. f. $A\,F$ of main motor and bearing constant ratio to $A\,D^1$ being due to the application of total induced e. m. f. $A\,F$ to the shunt field circuit of D, Fig. 10. $H\,G$* is resistance drop of $B\,E$ and $I\,G$ is the rotation e. m. f. produced by D of Fig. 10 by the voltage introduced into the field circuit by the existance of current $B\,E$ in primary of H. The angle α $(I\,G\,H)$ is determined by design and is, of course, constant, as is the ratio $\dfrac{G\,I}{H\,G}$.

$F\,K$ is total resistance drop, and $F\,L$ and $L\,K$ are components, due to $E\,D^1$ and $B\,E$. $K\,G = L\,H$ is compounding effect, due to $E\,D^1$, just as $G\,I$ is due to $B\,E$, so angle $H\,L\,F$ = angle $I\,G\,H = \alpha$ and is constant. Further $\dfrac{H\,L}{L\,F}$ is constant, so angle $L\,F\,H = \beta$ is constant and as $F\,L$ is parallel to $B^1\,D$ and $A\,F$ is perpendicular to $A\,D^1$, angle $B^1\,D^1\,A = \delta = 90$ deg. $- \beta =$ constant.

Therefore, D_1 traces the arc of a circle.

The slip S is equal to $\dfrac{A\,F}{A\,D^1}$ and at running light (zero torque) $E\,D^1$, $F\,L$, $H\,L$ and $K\,G$ become zero $\dfrac{A\,I}{A\,D^1}$ and angle γ are constant. Angles of triangle $I\,H\,G$ being constant and $G\,H\,A$ being 90 deg., we see that $I\,H\,A$ is also a constant angle, hence angle $A\,I\,H$ is constant. So $\dfrac{A\,H}{A\,D^1}$ is constant and as this is the expression for S_0, the running light slip where $H\,F$ is zero, we see that the slip, due to load $S_1 = \dfrac{H\,F}{A\,D^1}$, consisting of $L\,F$, due to the resistance and $H\,L$, due to the compounding action of the slip transformer. We thus see that the running light slip S_0 is adjustable by means of B in Fig. 10, while the load slip S_1 has been increased from $\dfrac{M\,F}{A\,D^1}$ to $\dfrac{H\,F}{A\,D_1}$ by the slip trans-

*Point H is on $A\,F$ because at zero load $B\,E$ becomes $B\,B'$, the total secondary current and $H\,G$ and $G\,I$ the only e. m. fs. to close the gap between $I\,A$ and $A\,F$. As $B\,H$ is proportional to $A\,D'$ and hence $A\,I$ and at constant angle thereto, H must remain on $A\,F$.

former. Further, it is apparent that by controlling the angle α we can make the power factor get more leading or more lagging as load comes on, and thus also, increase or decrease pull-out torque of the motor.

In defining the conditions assumed for Fig. 10, we mentioned that the leakage reactance drop of the regulating motor was supposed to be included in the voltage applied to the exciting winding. The actual effect of excluding it from this circuit can now be shown in Fig. 11-A, a modification of part of Fig. 11. The reactance in the regulating motor is, of course, not applied to its field, and hence the actual rotation e. m. f. for shunt excitation should not include $I^1 I$, the rotation e. m. f., due to the application of reactance drop

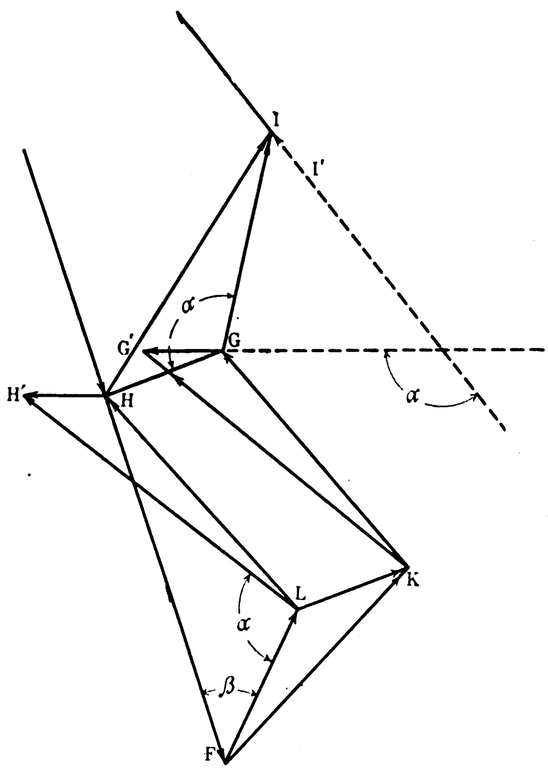

Fig. 11-a—Effect on Fig. 11 of Correctly Locating Resistance of Main Motor Secondary and Reactance of Regulating Machine

of $B E$ to the shunt field. Note that $I^1 A$ is the rotational e. m. f. of pure shunt excitation, and that as triangle $B E B^1$ is similar to triangle $A D^1 B^1$, $\dfrac{B E}{A D^1} = \dfrac{B B^1}{A B^1}$, hence $I^1 I$ is proportional to $I A$ and to $A D^1$ so that $A H$ is still proportional to $A D^1$. $G G^1$ and $H H^1$ are the rotational e. m. f., due to application of reactance drop of $E D^1$ to shunt field, and hence proportional to $E D^1$, so they may be excluded from $K G^1$ and $L H^1$, and for them may be used instead, $K G$ and $L H$. As angle $G^1 G K$ and $H^1 H L$ are fixed and as $H H^1$ and $G G^1$ are proportional to $H L$ and $G K$, we see at once that $H L$ is proportional to $L F$, angles $H L F$ (= angle $H L H^1 + \alpha$) and $H F L$ are constant, hence, $\delta = B^1 D^1 A = 90$ deg. $- \beta$ is constant and D_1 still traces a circle.

Thus when we consider the actual effect of the leakage reactance of the regulating motor we see that it is merely to alter the amount of compounding. Hence, to consider this in the case of Fig. 9, would mean to change it to a diagram like Fig. 11, with a small amount of compounding, the "pure shunt excitation" being only a hypothetical condition.

The magnetizing current of the regulating motor has so far been neglected. Neglecting regulating motor saturation, this is proportional to and in phase with $A D^1$ of Fig. 11. As it flows through the armature and compensating windings of the regulating motor only, its reactance drop can be added to the compounding just as was done in Fig. 11-A at $I I^1$ and its resistance drop, proportional to $B E$ can be added to the resistance drop of $B E$. Thus, we still would get our circle diagram. However, it does not usually pay to consider so small an element except as an interesting theoretical consideration.

The effect of the inclusion of the main motor resistance drop in the voltage applied to the regulating motor field of Figs. 8 and 9 may be treated similarly, providing we confine ourselves to operation so far from synchronism and at such a range of loads, that s_1 is a fairly small part of s_0, in which case the component of rotation e. m. f. caused by the resistance drop is approximately proportional to the current components.

Further the accuracy of the diagram developed so far hinges on the assumption that the values of S (distance from synchronous speed) are so great as to cause the variations in the relative values of the resistance and reactance drops of the shunt field circuit to be relatively small, which will mean a small variation in $H G$ of Fig. 9, since variations in the phase relation of field current and "total induced e. m. f." $A D^1$ mean variations in angle γ. As the resistance drop is larger and larger compared to the reactance drop the smaller the slip and frequency, it therefore appears that Figs. 9 and 11 are accurate only at fairly large values of slip, and small ratios of resistance drop to reactance drop in the field circuit, becoming inaccurate as synchronism is approached. Consideration of these effects has lead the writer to the use of a constant voltage frequency changer and adjustable resistance for overcoming and regulating the resistance drop of the field circuit, and of an auto-transformer with taps (and alternative devices) for overcoming the reactance drop, leading in turn to a feasible way of regulating the main motor through and above its synchronous speed as well as below.

Double-Range (All Speeds Above or Below Synchronism) Speed and Power Factor Control by Means of a Constant-Speed Shunt Commutator Motor

Several advantages of regulating the main motor speed above as well as below its synchronous value

appear at once. The capacity of the regulating set for a given maximum speed variation and maximum speed is reduced 50 per cent, provided the synchronous speed of the main motor is half way between the extremes. For if, S_{max}, S_{min} and S_s represent the maximum, minimum and synchronous speeds of the main motor and $H\,P_{max}$ be the horsepower capacity at speed S_{max}, we have for single range,—

$S_s = S_{max}$ and capacity of set is:—

$$H\,P_{set} = H\,P_{max} \times \frac{S_{max} - S_{min}}{S_{max}}$$

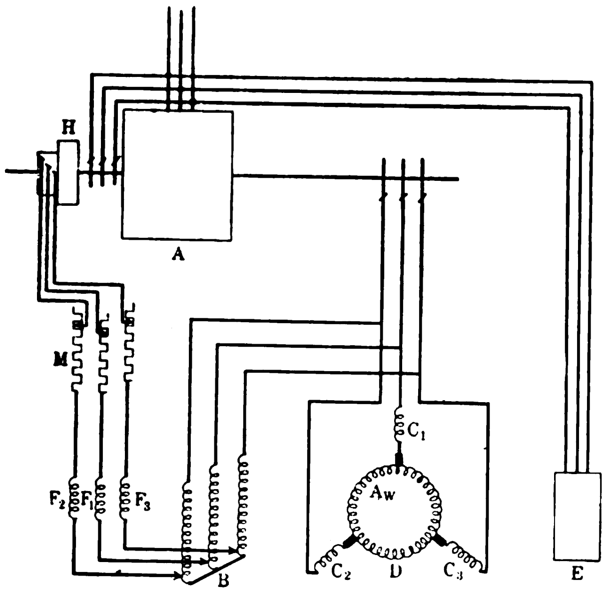

FIG. 12—NEUTRALIZED THREE-PHASE SHUNT A-C. COMMUTATOR MACHINE AND CONNECTIONS FOR ADJUSTABLE-SPEED CONTROL OF INDUCTION MOTOR FOR OPERATION BOTH ABOVE AND BELOW SYNCHRONISM.

Now for double range, as above, we have:—

$$2\,(S_{max} - S_s) = S_{max} - S_{min}$$

$$H\,P_{set} = H\,P_s \times \frac{S_{max} - S_s}{S_s} = \frac{H\,P_s}{S_s} \times \frac{S_{max} - S_{min}}{2}$$

But as $\frac{H\,P_s}{S_s} = \frac{H\,P_{max}}{S_{max}}$ we have,—

$$H\,P_{set} = 1/2\,H\,P_{max} \times \frac{(S_{max} - S_{min})}{S_{max}}$$

showing that the capacity of the double-range set is one-half that of the single range. Thus, not only will the first cost be materially less, but the machine losses will also be greatly decreased.

A second important advantage is that the synchronous speed of the main motor is in the middle of the speed range, so that often times many processes may be carried out running as plain induction motor with the set shut down, with consequent saving of wear and tear on it.

The apparatus, shown in Fig. 12, is the same as Fig. 8, except that instead of going to a star point the ends of shunt field coils F_1, F_2, F_3 are carried through the adjustable resistance M, to the frequency changer H mounted upon the shaft and wound for the same number of poles as main motor A. This machine has a single primary winding connected to a commutator exactly as in the armature of a d-c. machine, and has collector rings tapped in at points 120 electrical degrees apart (for three-phase power). The secondary is a smooth laminated ring without windings which may or may not rotate with the primary. Obviously, a "revolving field" is set up in this machine, which at standstill, rotates at synchronous speed of A and H. With 120 electrical degrees brush spacing on the commutator, we get three-phase full frequency voltage of the same value as we apply to the collectors neglecting machine drop, and the phase relating between the commutator and collector currents depends upon the position of the brushes on the commutator. Assume A to rotate synchronously in opposite direction to the rotation of flux of H, which carries said flux backward mechanically at the same rate that it is turning electrically, leaving it stationary in space, and permitting H to produce direct current at commutator like a synchronous converter.

Thus, it is seen that H is automatically a source of constant voltage at exact slip ring frequency.

If we regulate A at no-load (for simplicity) we see that the rotation e. m. f. of D, hence both its flux and field current are proportional to slip S. Hence the reactance drop component of the impedance drop of the field circuit, being proportional frequency as well as flux is proportional to S^2 while the resistance drop is merely proportional to the field current and to S. By connecting to taps of B whose distance from the star point is proportional to S, we get a voltage proportional to S^2, since the total e. m. f. of B is itself proportional to S. By changing taps on resistance M so that the entire resistance of the circuit is proportional to $1/S$, we just permit constant voltage frequency changer H to supply the resistance drop balancing e. m. f., while auto-transformer B furnishes reactance drop balancing e. m. f. In practise, one set of switches can be arranged to vary both M and B simultaneously.

With M operating at a considerable distance from synchronous speed, the field resistance drop can be exactly balanced for a given load by H, so that as B supplies the reactance drop, the conditions previously assumed are attained. From Fig. 9 it will be noted that the phase of $A\,F$ alters with load, while that of the voltage from H in Fig. 12 remains fixed. This only introduces a comparatively small discrepancy for working loads, the main effect being a slight alteration of the load slip.

Let us now, on the other hand, consider the case of running near synchronism, where the reactance drop of

the field, varying as S^2, and very nearly balanced by B has become practically ineffective. Fig. 13 is the simplest circle diagram for these conditions, the constant excitation of D, Fig. 12, from the frequency changer H being so chosen that, in Fig. 13, rotational e. m. f. $H\,A$ is perpendicular to line $A\,B\,C$ found as usual. $A\,F$ is the total induced e. m. f. of main motor secondary, $F\,H$ the resistance drop in main secondary circuit for secondary current $B\,D^1$.

Resolve $F\,H$ into components $F\,G$ in phase opposition to $A\,F$ and $G\,H$ perpendicular to $A\,F$, and $B\,D^1$ into corresponding components $B\,D$ and $D\,D^1$, (Point

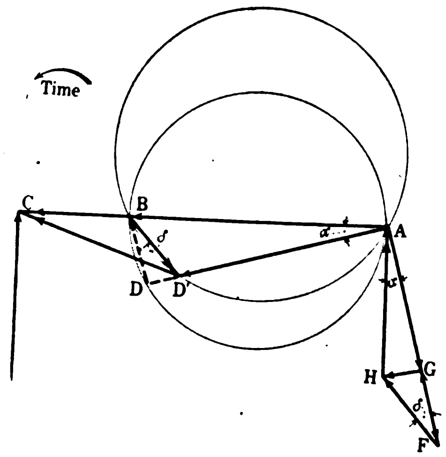

Fig. 13—Circle Diagram of Induction Motor Running below Synchronism with Regulating Machine Receiving Constant Shunt Excitation without No-Load Power Factor Improvement

D, thus traces the circle of the main motor with regulating motor reactance included, but with $A\,H$ left out of the circuit)

$$G\,H = H\,A \sin \alpha$$

$$F\,H = \frac{G\,H}{\sin \delta} = \frac{H\,A \sin \alpha}{\sin \delta}$$

$$B\,D = A\,B \sin \alpha$$

$$B\,D^1 = \frac{B\,D}{\cos \delta} = \frac{A\,B \sin \alpha}{\cos \delta}$$

Further, $$B\,D^1 = \frac{F\,H}{r_{2+c}}$$

So $$\frac{H\,A \sin \alpha}{r_{2+c} \times \sin \delta} = \frac{A\,B \times \sin \alpha}{\cos \delta}$$

And $$\tan = \frac{H\,A}{A\,B} \times \frac{1}{r_{2+c}}$$

As $H\,A$, $A\,B$ and r_{2+c} are constant,
Angle δ must be constant.

Angle $B\,D^1\,A$ is 90 deg. + δ, hence D^1 traces a circle.

In Fig. 14, we have given the excitation, and hence, the rotation voltage $A\,H$ a shift β from its position in Fig. 13, so as to improve the power factor.

Resolve the resistance drop $F\,H^1$, of the secondary current $B^1\,D^1$ (A, B^1 and C being the usual fixed points) into $H^1\,H$ perpendicular to $H\,A$ perpendicular to $A\,B$, and $F\,H$, corresponding current components being $B\,B^1$ and $B\,D^1$. Since $H^1\,A$ and angle β are constant, H and B are fixed points. Now resolve $F\,H$ into $F\,G$ along $A\,F$ and $G\,H$ perpendicular to $A\,F$, also $B\,D^1$ into corresponding components $B\,D$ and $D\,D^1$. D^1 may now be shown to trace arc of circle $B\,D^1\,A$ as in Fig. 13. We note the power factor and pull-out torque are better than for Fig. 13.

As we are considering operation at rather small values of slip where the shunt excitation is all from H and M of Fig. 12 and is not effected by B, we can compound by the use of plain series windings as with d-c. machines without interference by transformer action.

In Fig. 15, we have shown the effect of such compounding, brought about by making changes in the neutralizing winding C_1; C_2, C_3. It can be demonstrated that a polyphase armature turning above its own synchronous speed in the field, set up by its own reaction generates a rotation voltage leading the current by 90 deg. Hence, by weakening $C_1\,C_2\,C_3$, we can get this sort of compounding in any desired degree.

$A\,B^1\,C$ denote the usual fixed points of the main motor with reactance of regulating motor included. $H^1\,A$ is the fixed excitation from frequency changer and rheostat and $B^1\,B$ is running light secondary current, due to $H^1\,I$, $B^1\,D$ being load current considered. $A\,F$ is the total secondary induced e. m. f.

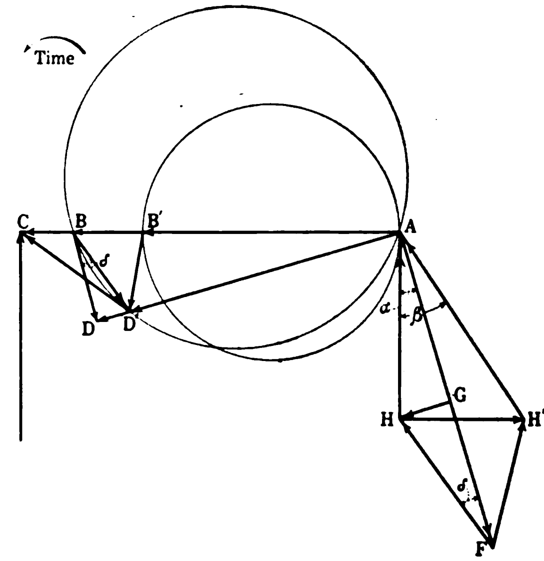

Fig. 14—Circle Diagram of Induction Motor Running Below Synchronism with Regulating Machine Receiving Constant Shunt Excitation, such as to Give No-Load Power Factor Improvement

The secondary current $B^1\,D$ consists of a constant component $B^1\,B$ and variable component $B\,D$. $I\,H^1$ is the constant resistance drop and $H\,I$ the constant leading rotation e. m. f., due to component $B^1\,B$, making H a fixed point. $G\,H$ is resistance drop and $F\,G$ leading rotation e. m. f. of variable component $B\,D$. Now the resistance drop and the variable rotation

e. m. f. are each proportional to the current (the iron of the regulating motor is always at low densities for these near synchronism conditions) hence, angle $H F G = e$ is constant. Since H is a fixed point, angle $H F K = \delta$ can be shown to be constant as in Fig. 13. Angle $K F G = \theta = c + \delta$ = constant. Angle $B D A$ is also equal to θ, since $A D$ is perpendicular to $A F$ and $B D$ is perpendicular to $F G$. So D traces arc of a circle, passing through A and B.

It will be seen then that the power factor and pull-out torque can be improved as well as the speed regulated by this method, when regulating near synchronism, as well as remote therefrom. When we regulate the speed, we so adjust the taps of B, Fig. 12, as to get

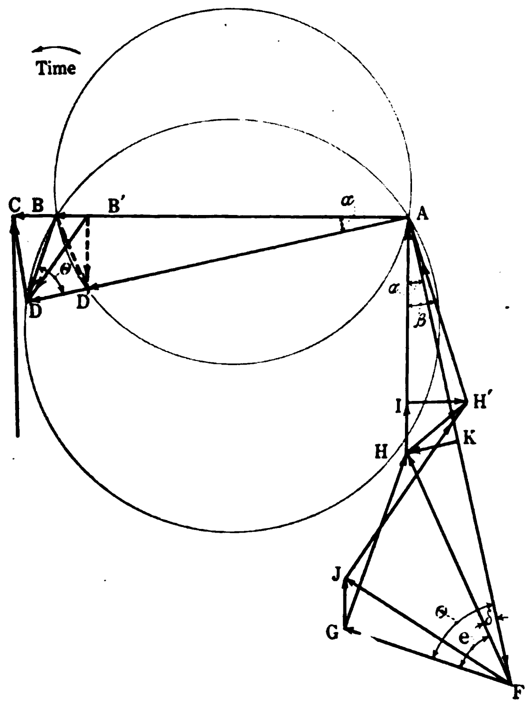

Fig. 15—Circle Diagram of Induction Motor Running Below Synchronism with Regulating Machine Compound-Excited, the Shunt Excitation Being Constant and Having No-Load Power Factor Improvement, and the Series Excitation Yielding E. M. F. 90 Deg. Ahead of the Current

the desired percentage of slip voltage from $F_1 F_2 F_3$ to overcome the reactance drop and then so adjust resistance M that the field current corresponding to the desired conditions will have a resistance drop equal to the voltage supplied by H. As the field current is about constant over the working range of loads we can thus get an even better approximation to Figs. 9 and 11 than without H and M. As we regulate the speed, we thus transfer gradually from the condition of Figs. 9 and 11 to those of Figs. 13, 14 and 15.

We have drawn Fig. 16 to examine the phenomenon of regulating the speed of the main motor while loaded from an infinitesimal amount below synchronism to an infinitesimal amount above synchronism. As the slip is negligible, the total induced e. m. f. is also negligible and the rotational e. m. f. of the regulating set $A H$ just supplies the resistance drop $H A$, the main motor being assumed to be a trifle below synchronism. Let us now assume it to be an infinitesimal amount above synchronism.

All vectors are referred to the secondary whose phase rotation has been reversed, although the physical condi-

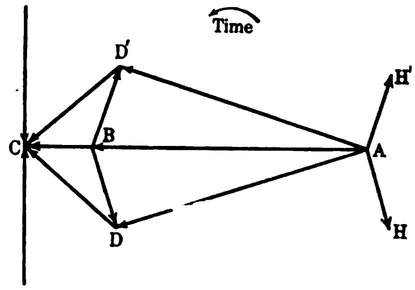

Fig. 16—Diagram of Induction Motor Running Loaded at Synchronous Speed

The same conditions are represented as infinitesimally below and as infinitesimally above synchronism.

tions in the motor remain unchanged. If we select the phase of $A C$ as the phase of reference for both phase rotations, then the components of all vectors in phase with it will not be altered by reversal of the phase rotation, but the quadrature components of all vectors will be reversed, as a vector which would not reach its maximum until 90 deg. after $A C$ will, in reversed phase rotation, reach its 90 deg. ahead of $A C$. This law

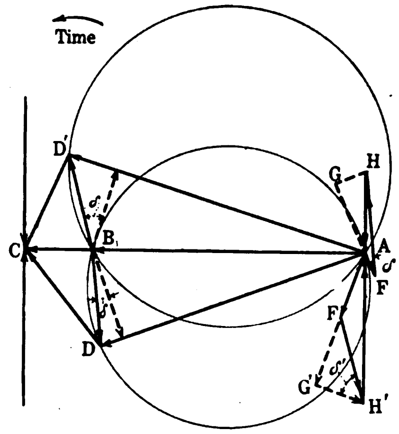

Fig. 17—Circle Diagram of Induction Motor and Constant-Excitation Regulating Machine with One Value of Excitation such that Speed for the Load Point Shown is Nearer Synchronism than the Natural Slip Value and Another Value of Excitation such that Speed for the Load Point Shown is Above Synchronism

yields us $H^1 A D^1 B C$ to represent the same phenomena in terms of reversed phase rotation as are shown by H, A, D, B, C with original phase rotation in the secondary.

In Fig. 17, D is a load point with motor nearer synchronism than its natural slip, as the rotation e. m. f. of the regulating motor $H A$ has been reversed so as to have a large component in phase with the total induced e. m. f., $A F$. The bulk of the resistance drop $F H$ is, therefore, supplied by $H A$, so that $A F$ and consequently the slip are reduced. In these conditions

the motor would pass through and above synchronism as the load dropped off.

Let us now increase $H A$ until the main motor runs above synchronism (with reversed secondary phase rotation). As $H A$ was in quadrature to $A C$, the line

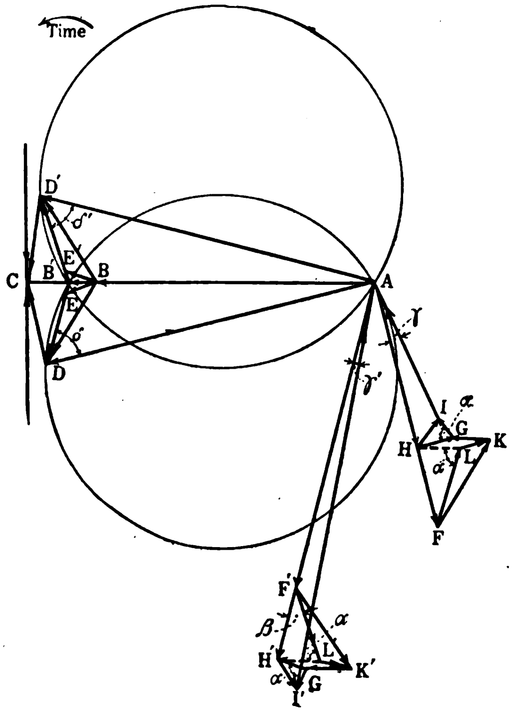

Fig. 18—Circle Diagrams of Induction Motor Running Below Synchronism and Above Synchronism with the Same Characteristics, Controlled in Each Case by a Compound Constant-Speed Regulating Machine

of the phase of reference, its new value will be shown with reversed direction at $H^1 A$. Load point D^1 is above line $A C$ for motor torque for the same reason. The total induced e. m. f. would also be represented with its quadrature component above $A C$ instead of

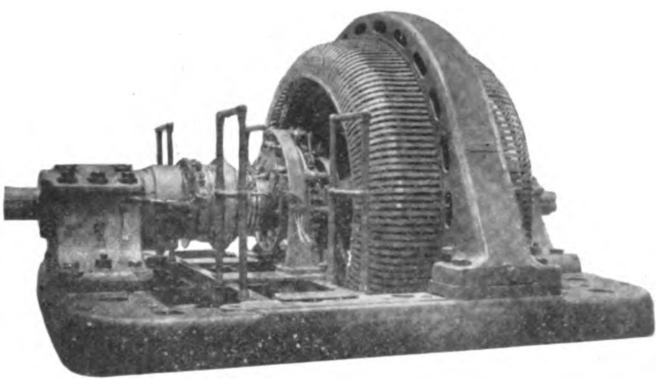

Fig. 19—1200-H.P. Rolling Mill Motor with Frequency-Changer Exciter

below, but its direction is actually reversed, as shown at $A F^1$, since at any instant any given conductor now cuts the flux in the opposite direction.

We note that with no initial quadrature or power factor component in $H A$, and $H^1 A$, the motor characteristic when running above synchronism is better than below in respect to power factor and maximum torque, while for the generator characteristic the converse is true.

Double-Range (Either Above or Below Synchronism) Operation Remote from Synchronism

In Fig. 18, we represent operation both above and below synchronism, with the same speed—torque and speed — power factor conditions. The configuration indicated by the plain letters is for using a compound commutator motor similar to that of Fig. 11, except that angle α has been decreased so that the compounding is mostly in the way of power factor improvement and adds very little to the slip. The primed letters indicate the relations for operating above synchronism and angle $A D^1 B^1$ equals δ can be shown to be constant just as in the case of angle $A D B^1$. Keeping the phase of $A C$ as the phase of reference we note as before that the representation in secondary terms with reversed phase rotation requires the reversal of the components in quadrature with $A C$ of all vectors, and as $A F^1$ is further actually reversed in passing above synchronism,

Fig. 20—A Frequency-Changer Exciter

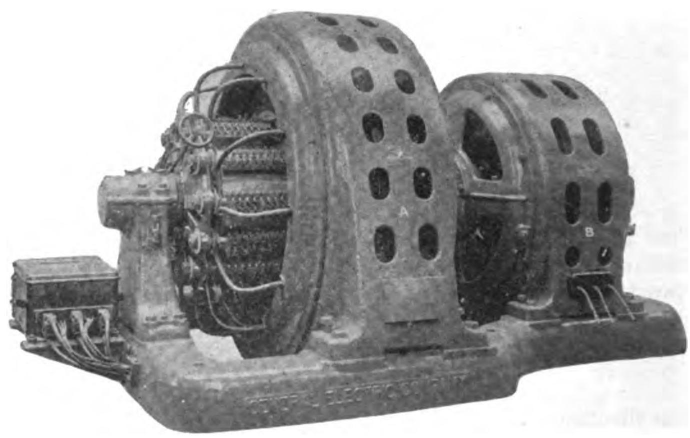

Fig. 21—Speed-Regulating Set for a 1600-H.P. Motor

we see that its quadrature components are still in phase with that of $A F$. But as the regulating machine must furnish power to the main motor secondary in order to satisfy the conservation of energy, the total current $B D^1$ must have a component in phase with the rotation e. m. f. $I^1 A$, which we see is the case, thus requiring that $I^1 A$ be larger than $A F^1$ fulfilling the condition that the regulating machine function as a generator.

Note:—For the development of the circle diagram, particular mention should be made of the works of Behrend, Blondel and Arnold-LaCour. Meyer-Delius has also written concerning what the writer has termed Single-Range Regulation.

The Audion Oscillator

BY R. A. HEISING

Research Laboratory, Western Electric Co., Inc., and American Tel. & Tel. Co., New York

(*Continued from page* 376 *of JOURNAL for April, 1920*)

18. Operating Point on the Characteristic Curve

By operating point on the characteristic curve is meant the point on the $E_c - I_b$ curve of the audion about which the grid potential and space current vary. E_c is the potential of the grid with respect to the filament. If a continuous negative potential such as Q Fig. 36 is applied, the point about which the variations occur is B. There are several reasons why it is preferable to have B as the operating point rather than A. If A is the operating point, the alternating voltage on the grid makes the grid become positive with respect to the filament during one-half of the cycle, and during that time current flows from the grid to the filament within the audion. This current heats the grid and absorbs power. If the operating point is B, the grid does not become positive with respect to the filament

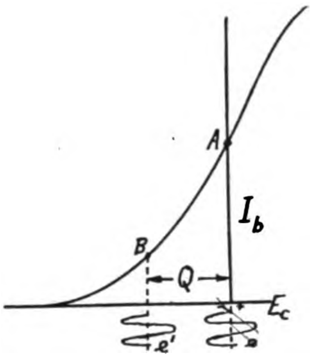

Fig. 36—Operating Points on a Characteristic Curve

at any time and it absorbs no power in varying the grid potential. By using a negative potential on the grid the audion requires no power for varying the grid potential.

If the point A is used as the operating point, the space current flowing is much greater than at B. To maintain the space current at point A requires twice as much filament in an audion as to maintain it at B. At a given temperature (and therefore life of the audion) the space current is dependent upon the amount of filament rather than the voltage used, as the filament is not heated any hotter than is needed to emit the required number of electrons. If we put the same amount of power into an audion at high plate voltage and small plate current (B) as we do with the smaller plate voltage and higher plate current (A), a saving in the required filament and filament power occurs.

19. Methods of Obtaining a Constant Negative Potential

The usual method of securing a constant negative potential for the grid is to use a battery for the purpose Fig. 37. The only objections to such a scheme are the capacity added to the circuit by the battery and the latters likelihood of deteriorating. The scheme shown in Fig. 38 avoids these objections. C_1 is a condenser of low reactance at the operating frequency, and R_1 is a resistance of the order of 10,000 ohms shunting the condenser. Oscillations start with no negative potential on the grid (point A in Fig. 36) and the rectified grid current resulting passes through R_1. In doing so, the rectified current produces a negative voltage which moves the operating point from A toward B. The amount of rectified current produced is reduced, as the

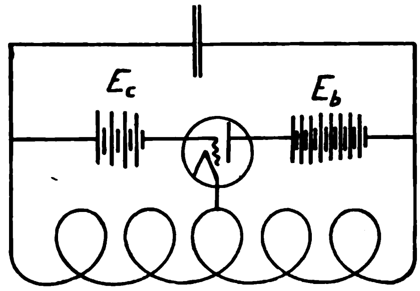

Fig. 37—Hartley Circuit with a Negative Battery for Grid

operating point moves towards the left, due to the smaller time the alternating wave makes the grid positive. The point of equilibrium is reached when this part of the alternating voltage wave is just sufficient to maintain the rectified current through R_1 which produces the continuous negative potential mentioned.

The simplicity of this system is such that it is used in practically all power oscillators. The condenser C_1 is called the grid stopping condenser and the resistance R_1 is called the grid resistance. The latter is sometimes called the grid leak resistance.

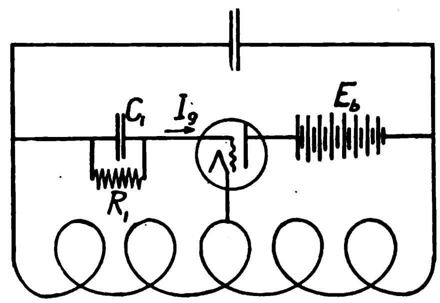

Fig. 38—Hartley Circuit with a Grid Resistance

The behavior of an oscillator with a negative grid battery is different in some ways from that of one with a grid stopping condenser and resistance, as will be indicated later.

20. Dynamic Characteristic of an Audion with Attached Circuit

The static characteristic curve of the audion is as given in Fig. 36. This is the condition of a constant potential on the plate at all grid potentials. When a circuit is attached to the plate of the audion, the potential on the plate no longer remains constant for

all space currents but drops when the current rises. As a result, the curve between the space current and grid potential departs from that given in Fig. 36, and becomes as shown in Fig. 39. It is known as the dynamic characteristic curve of the audion and its circuit. The curve in Fig. 39 is for a pure resistance load circuit $- R$. The load circuit in this diagram is so drawn that the direct current to the audion flows through a large choke coil "*c h*" and produces little or no voltage drop, while all variable currents must pass through the parallel load resistance Z. The effect of the attached circuit is to flatten and straighten the characteristic curve. If the attached impedance is infinite ($Z = \alpha$) the dynamic curve becomes a horizontal straight line.

If an inductive circuit is attached, as in Fig. 40, the dynamic curve becomes a closed loop traveled around in the direction indicated by the arrow. If the circuit has a capacitive reactance as in Fig. 41, the dynamic curve is also a closed loop but it is traveled around in a direction opposite to the one in Fig. 40. These curves must not be confused with hysteresis loops as there is

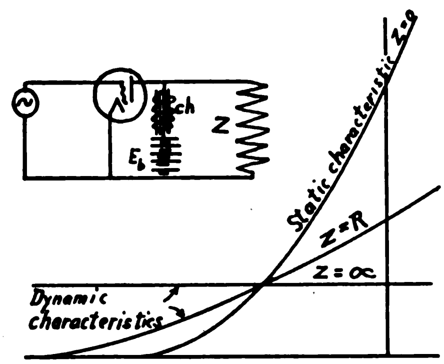

Fig. 39—Static and Dynamic Characteristic Curves with Resistance Load

no connection between them. Hysteresis loops indicate power absorbed. These loops indicate wattless power and are identical in theory with curves plotted between the instantaneous values of an alternating voltage and the resulting current flowing in an inductive or condensive circuit.

21. Coupling for Power

To get the maximum power out of an oscillation generator, the impedance of the attached load circuit must be equal to the internal impedance of the generator, have equal resistance, and have an opposite reactance sign. The internal impedance of an audion is a pure resistance (except at very high frequencies). Ordinary electrical generators are not operated on this principle. If the external impedance equals the internal impedance, a separately excited power generator would have 100 per cent regulation and 50 per cent efficiency. The extra power secured is not worth this sacrifice in efficiency in power work, so that all power machines are constructed to deliver much less than the maximum possible power at a high efficiency.

In audion circuits, a direct current is superimposed on the alternating space current and represents power entirely lost. The maximum possible efficiency is a little over 50 per cent in any case. We must choose, in this class of work, between maximum power (from a given audion) with low efficiency, or a reduced power with a higher efficiency. By operating at a higher voltage, the latter case can give the same power as the former, and we have actually to compare low efficiency (40 per cent) and low voltage, with high efficiency (60

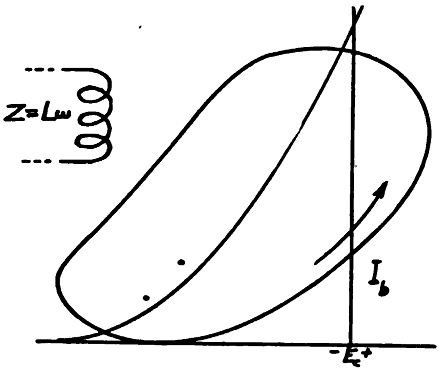

Fig. 40—Dynamic Characteristic with Inductive Load

per cent) and higher voltage. The higher voltage requires more carefully constructed audions, and introduces the attending troubles of higher voltage generators, so that the choice becomes an economic balance between more expensive audions and generators, and the cost of the extra power required in operating the low efficiency circuits. It has been found practicable to choose between these limits in the work to date.

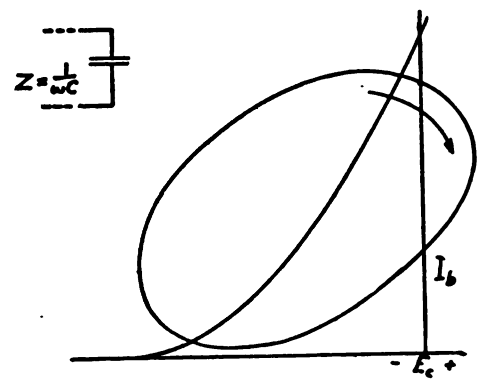

Fig. 41—Dynamic Characteristic with Capacitive Load

22. Audion Output Impedance

The internal impedance (or output impedance) of an audion has been shown by Van der Bijl to be

$$Z_o = \frac{E_b + \mu E_c}{2 I_b} \qquad (3)$$

It is determined by the slope of the $E_b - I_b$ curve at the point of operation. The output impedance Z_o, for the point P, is shown in Fig. 42. For a given audion it is a function of the current, rather than the potentials, for Z_o remains constant as long as the current remains the same, even though E_b and E_c vary. The value of Z_o can be determined from a curve plotted as shown,

although other and quicker ways of measuring it are known.

The output impedance of an audion used in an oscillator is different from the above. The output impedance as defined assumes that the square law characteristic holds, which means that the part of the actual curve over which the operation occurs is limited. The actual characteristic curve of the audion is of the general form shown in Fig. 43, and the operation usually includes the entire region between A and B. For

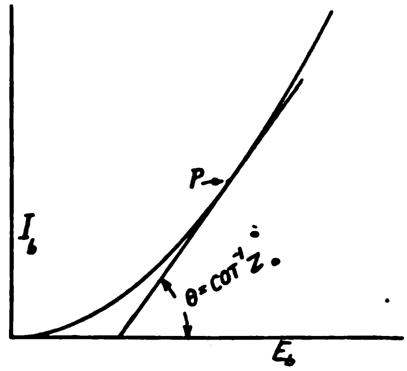

Fig. 42—Relation of Output Impedance and Characteristic Curve Slope

limited amplifier operation, the output impedance is μ times the reciprocal of the slope at P, while for oscillator work it should be more nearly equal to μ times the slope of a line connecting A and B. It actually falls between these two values.

At very high frequencies the output impedance is no longer a pure resistance, due to the plate capacity within. With the internal impedance having a capacitive reactance, it becomes necessary to use a load circuit having an inductive reactance, if maximum power is desired.

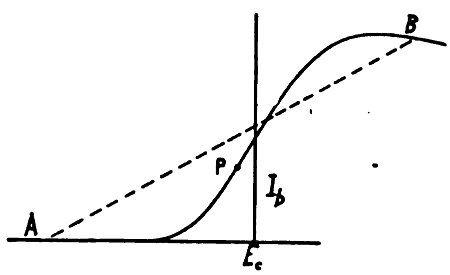

Fig. 43—Influence of Grid and Unsaturated Filament Upon the Form of the Upper Part of the Characteristic Curve

The output impedance of the oscillating audion is most easily determined directly. A curve showing the variation of power secured as a function of the impedance of the load circuit is shown in Fig. 44. The maximum power is secured at the point marked X. This value of impedance is called the output impedance for the oscillating audion.

This curve can be secured by using any of a number of oscillator circuits and varying the coupling between the plate circuit and the oscillation circuit. The one used for this purpose is the one indicated in Fig. 46 where C_p was the adjustable coupling capacity and C_2 was adjusted to compensate for frequency changes produced by varying C_p.

23. Coupling Adjustments

The power delivered by the audion in an oscillator circuit is transferred to the oscillation circuit by means of inductive coupling in the Hartley circuit, and capacitive coupling in the Colpitts circuit. In order to adjust

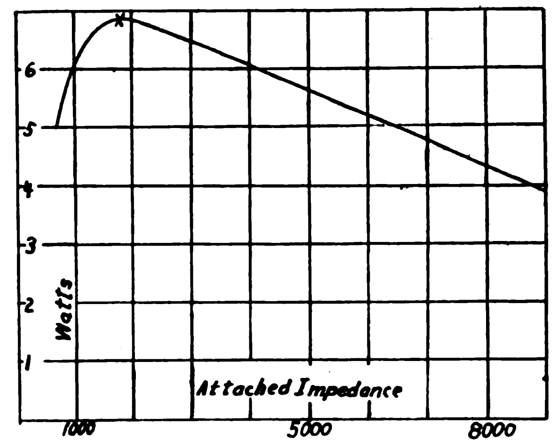

Fig. 44—Influence of Load Circuit upon Output

the impedance introduced into the plate circuit by the oscillation circuit to the proper value, means must be provided for adjusting this coupling. In Fig. 45 the method of making this adjustment for the Hartley oscillator is shown. The inductance L_o is tapped at various points and the connection from the plate is moved along these points until the proper coupling is secured.

There is a limit to which the coupling in this type of circuit can be reduced, due to inherent capacity within

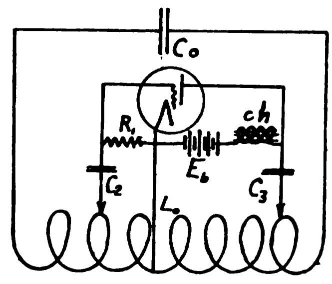

Fig. 45—Adjustments of the Hartley Circuit

the audion. When the amount of L_o included between the plate and grid coupling connections is reduced to a small part of the total inductance, a second oscillator circuit is formed having this inductance as the oscillation circuit inductance and the grid to plate capacity as the oscillation circuit capacity. At the high frequency of this parasitic oscillation circuit the remaining part of L_o and C_o has a large inductive reactance and does not affect its oscillations. The circuit when constructed in this maner is likely to operate entirely at

the high parasitic frequency and not at the frequency for which the circuit was originally designed. The Colpitts circuit avoids this particular kind of trouble.

Fig. 46 shows a Colpitts circuit with a method of adjustment. The plate coupling is adjusted by varying C_p. However as this adjustment changes the frequency, a second adjustable condenser C_a is needed to bring the frequency back to the desired value. This circuit has the disadvantage that two adjustments are

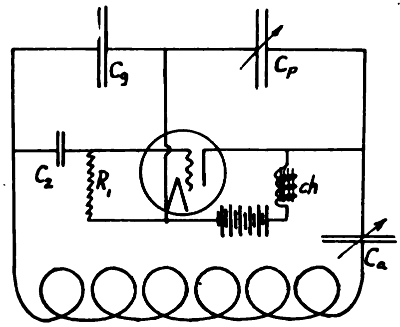

Fig. 46—One Manner of Adjusting the Colpitts Circuit

necessary for one adjustment of coupling, a condition which is not required in the Hartley circuit.

To avoid this double adjustment, and also to avoid the Hartley circuit troubles, a modified method of adjustment can be made as shown in Fig. 47. Instead of varying the condenser C_p, the mutual capacitive reactance is varied by introducing, in series, a varied amount of inductive reactance. This is secured by moving the coupling tap along the inductance coil L_o. The reactance of the inductance connected between C_p and the coupling point Q is opposite in sign to the reactance of C_p itself and thereby changes the mutual reactance. The adjustment of coupling in this manner

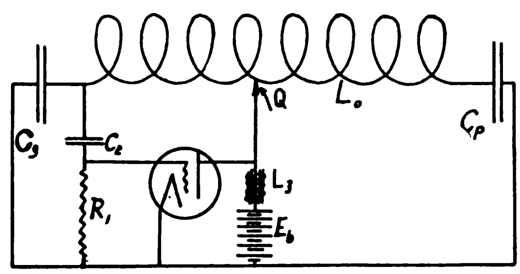

Fig. 47—Complete Colpitts Circuit with Coupling Adjustment

does not affect the wave-length appreciably nor produce a parasite frequency circuit, as in the Hartley circuit.

24. Audion Load Circuit

The circuit connected between the plate and filament of an audion is called the load circuit. In the Hartley circuit it has the actual form shown in Fig. 48, and is electrically equivalent to that shown in Fig. 49. The mutual inductance, in the first case, is the mutual between L_1 and all of L_2, and is to be the same as M in the second case. If an alternating voltage E is impressed across L_1 (or L_3), power is transferred to the oscillation circuit $L_2\,C_2$ (or $L_4\,C_4$) by this mutual inductance. The current through L_1 (or L_3) will have the value

$$I = \frac{E}{\sqrt{(R_1 + R_i)^2 + (X_1 + X_i)^2}} \tag{4}$$

where R_1 and R_i are respectively the primary resistance and the resistance introduced, and X_1 and X_i are respectively the primary reactance and the reactance introduced from the secondary. The values of resist-

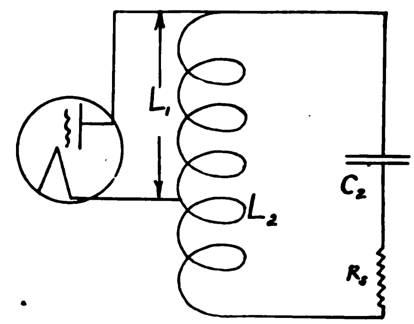

Fig. 48—Hartley Circuit Coupling

ance and reactance introduced due to the mutual reactance are

$$R_i = \frac{M^2\,\omega^2\,R_s}{R_s^2 + \left(L_s\,\omega - \dfrac{1}{\omega\,C_s}\right)^2} \tag{5}$$

$$X_i = -\frac{M^2\,\omega^2\left(L_s\,\omega - \dfrac{1}{\omega\,C_s}\right)}{R_s^2 + \left(L_s\,\omega - \dfrac{1}{\omega\,C_s}\right)^2} \tag{6}$$

where R_s, L_s and C_s are the secondary resistance, inductance, and capacity. The form of these curves are given in Fig. 50.

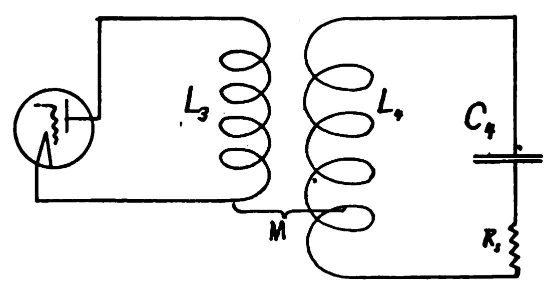

Fig. 49—Equivalent of Coupling of Hartley Circuit

Inspection of these equations will show that at the resonant frequency of the secondary

$$R_i = \frac{M^2\,\omega^2}{R_s} \tag{7}$$

$$X_i = 0$$

or resistance only is introduced into the primary. The minus sign in front of the reactance term indicates that at other frequencies when the reactance in the secondary circuit is inductive, the reactance introduced into the primary is capacitive, and vice versa. Above resonance, the secondary circuit has inductive reactance and may introduce enough capacitive reactance into

the primary to more than neutralize the primary inductive reactance. The reason circuits of this kind sometimes tune at a higher frequency than the resonant frequency of the secondary is because under these conditions enough capacitive reactance is introduced

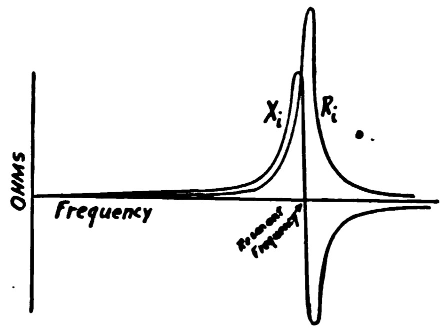

FIG. 50—RESISTANCE AND REACTANCE INTRODUCED INTO THE PRIMARY FROM THE SECONDARY CIRCUIT

into the primary to resonate with the primary inductance and improve the power factor of the entire primary circuit. Under these conditions the applied e. m. f. will deliver more power to the circuit which makes itself evident by a larger secondary current.

For a capacitive coupling between the audion and the oscillation circuit, as in Fig. 51, the resistance and reactance values are

$$R = \frac{(R_1 R_2 - X_1 X_2)(R_1+R_2) + (R_1 X_2 + R_2 X_1)(X_1+X_2)}{(R_1+R_2)^2 + (X_1+X_2)^2} \tag{8}$$

$$X = \frac{(R_1+R_2)(R_1 X_2 + R_2 X_1) - (X_1+X_2)(R_1 R_2 - X_1 X_2)}{(R_1+R_2)^2 + (X_1+X_2)^2} \tag{9}$$

where $X_1 = -\frac{1}{\omega C_1}$ and $X_2 = \left(L_2\,\omega - \frac{1}{\omega C_2}\right)$

If $R_1 = 0$, a condition approximated in practise,

$$R = \frac{\left(-\frac{1}{\omega C_1}\right)^2 R_2}{R_2^2 + \left(L_2\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2}\right)^2} \tag{10}$$

$$X = -\frac{1}{\omega C_1} - \frac{\left(-\frac{1}{\omega C_1}\right)^2 \left(L_2\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2}\right)}{R_2^2 + \left(L_2\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2}\right)^2} \tag{11}$$

which have the identical form of the equations with inductive coupling, but with a reactance $-\frac{1}{\omega C}$ replacing $M\,\omega$. The equations give curves of the form shown in Fig. 51.

In the actual Colpitts circuit, the coupling adjustment shown in Fig. 47 gives a more complicated expres-

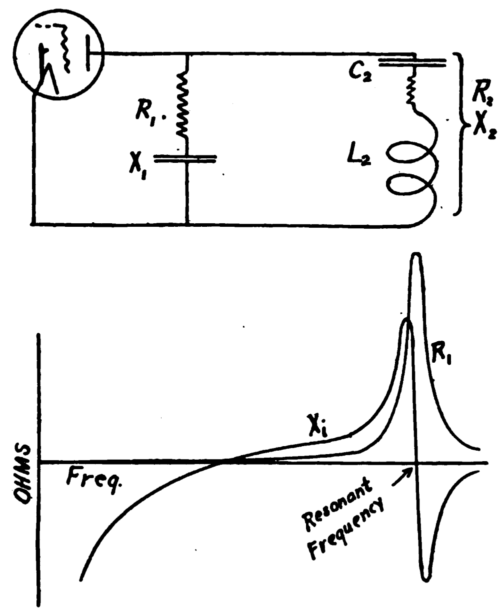

FIG. 51—CAPACITIVELY COUPLED CIRCUIT WITH ITS RESISTANCE AND REACTANCE CURVES

sion. The load circuit is also shown in Fig. 52 where the parts of the inductance acting as mutual reactance are called L_1 and the remainder L_2. The values of resistance and reactance connected to the audion plate circuit with this arrangement are given by

$$R = \left[\frac{\left(R_1 R_2 - \left(L_1\,\omega - \frac{1}{\omega C_1}\right)\left(L_2\,\omega - \frac{1}{\omega C_2}\right) + M^2\,\omega^2\right)(R_1+R_2) + \left[R_2\left(L_1\,\omega - \frac{1}{\omega C_1}\right) + R_1\left(L_2\,\omega - \frac{1}{\omega C_2}\right)\right]\left[L_1\,\omega + L_2\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2} + 2\,M\,\omega\right]}{(R_1+R_2)^2 + \left(L_1\,\omega + L_2\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2} + 2M\,\omega\right)^2}\right] \tag{12}$$

$$X = \frac{\left[R_2\left(L_1\,\omega - \frac{1}{\omega C_1}\right) + R_1\left(L_2\,\omega - \frac{1}{\omega C_2}\right)\right](R_1+R_2) + \left[L_o\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2}\right]\left[R_1 R_2 - \left(L_1\,\omega - \frac{1}{\omega C_1}\right)\left(L_2\,\omega - \frac{1}{\omega C_2}\right) + M^2\,\omega^2\right]}{(R_1+R_2)^2 + \left(L_o\,\omega - \frac{1}{\omega C_1} - \frac{1}{\omega C_2}\right)^2} \tag{13}$$

which produce curves of the form in Fig. 52.

At the resonant frequency of the oscillation circuit they reduce to

$$R = \frac{R_1 R_2 + M^2 \omega^2 - \left(L_2 \omega - \frac{1}{\omega C_2}\right)\left(L_1 \omega - \frac{1}{\omega C_1}\right)}{R_1 + R_2} \tag{14}$$

$$X = -\frac{R_1\left(L_2 \omega - \frac{1}{\omega C_2}\right) + R_2\left(L_1 \omega - \frac{1}{\omega C_1}\right)}{R_1 + R_2} \tag{15}$$

25. Oscillator Behavior as a Function of Its Variables

An oscillator constructed in the manner outlined, has, when designed for a certain frequency, six independent variables which influence its operation. These

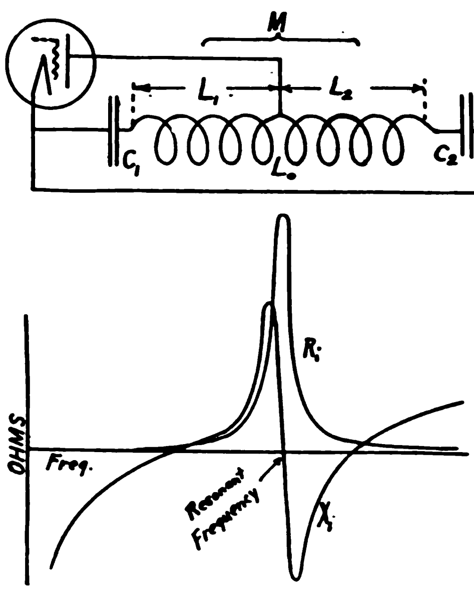

Fig. 52—Coupling Circuit of the Colpitts Oscillator with its Resistance and Reactance Curves

are, plate voltage, filament voltage or current, plate coupling, grid coupling, oscillation circuit resistance, and grid resistance. The three dependent variables which indicate its behavior are, space current, grid current, and oscillation current. These independent variables do not include variations in audion constants for different audions, but are concerned only with the behavior of the circuit having a particular audion. They also do not include variations in elements of the circuit which ordinarily should have zero or infinite impedances such as the grid stopping condenser C_2 and the choke coil L_3 Fig. 47.

The plotting of a curve, surface, solid, etc. to represent the oscillator behavior as a function of the six variables is beyond the realm of possible geometry and it devolves into the plotting of six sets of curves under arbitrarily chosen conditions. To show completely the circuit behavior, a large number of combinations should be chosen. However, it has been found that certain elements have greater influence than others and the number required can be reduced. It has been found sufficient to plot families of curves using R_1 as one independent variable and each of the other five variables in turn, as another, and secure a very informative set of curves. The circuit used to give the following curves was adjusted to a best operating condition,

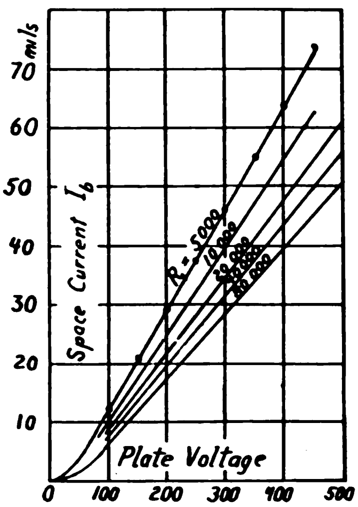

Fig. 53—Oscillator Space Current as a Function of Plate Voltage

as will be pointed out later, and then each independent variable successively varied, but always returned to its original value while another variable was being changed. The curves therefore show the behavior of the oscillator around the point of best operation, as a function of each of the six independent variables in turn, or as a function of R_1 and one of the other five variables in turn.

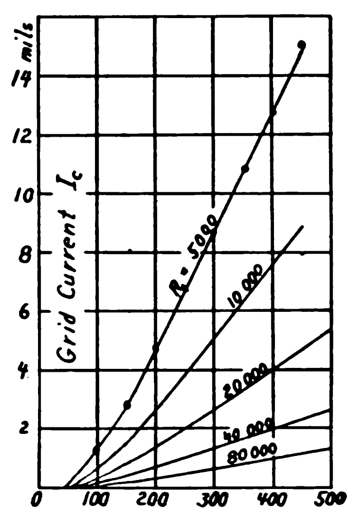

Fig. 54—Oscillator Grid Current as a Function of Plate Voltage

26. Variation as a Function of E_b

The space, grid, and antenna currents I_b, I_c, and I_a all vary as straight line functions of E_b except at the very ends of the curves, where either oscillations do not occur or filament temperature saturation does not occur. Curves are shown in Figs. 53, 54 and 55 for an

E type Western Electric audion with various values of R_1. All the curves converge toward a value of E_b equal to about 50 volts, which means that no oscillations occur until about that value is reached.

The use of a grid resistance instead of a negative grid battery makes quite a difference in the shape of these curves. In Fig. 56 curves are shown of I_b and I_d as a function of E_b, for the latter case. The oscillations do not start as low and make a big jump when they do start. Further, there is a place where a different path is followed with a decreasing plate voltage rather than with an increasing voltage. The simple behavior of the circuit with the grid resistance is an additional reason for using it in place of a constant negative potential on the grid.

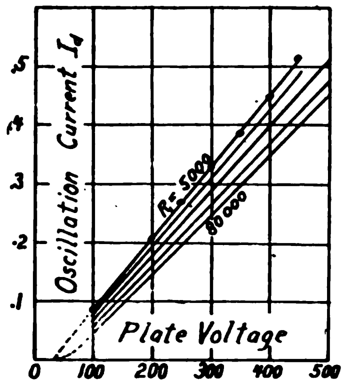

Fig. 55—Oscillation Current as a Function of Plate Voltage

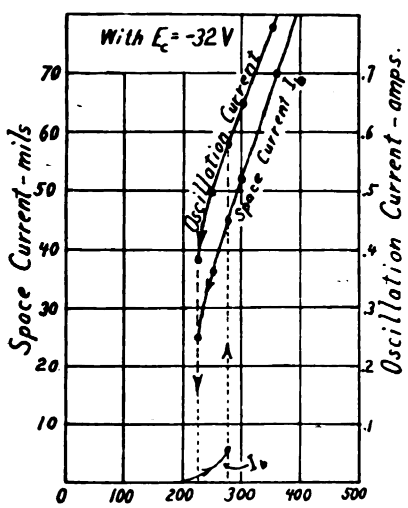

Fig. 56

27. Variation with Filament Current

The control of the filament current of an oscillator is as important as the regulation of any power generator. The filament current bears about the same relation to an audion that the field current does to a generator. It acts as an exciter, and produces the free electrons by thermal emission. It is, however, a much more sensitive exciter than the generator field current since the emission of electrons only begins at about two-thirds the operating value of the current and is not proportional to it but varies rapidly with it. A curve showing the oscillator behavior as a function of filament current is shown in Fig. 57. The variation of power output with filament current is very large at some points, but above about 1.35 amperes it changes very slowly. It is highly desirable to make the oscillator's operation independent of as many variables as possible and, by keeping the filament current above 1.36 amperes, the fluctuations in filament current have little or no effect. At the same time is it not desirable to run the filament current higher than is necessary, as the life of the audion is shortened thereby.

The filament current at which oscillations begin in the type E audion varies from 1.0 to 1.25 amperes depending upon the emissivity of the filament. A filament with very good emission begins at the lower value, and the curve flattens off at the value of 1.15 amperes. A passable filament begins at 1.25 and reaches the flat portion of the curve at 1.4 amperes. The average filament is such that oscillations begin at

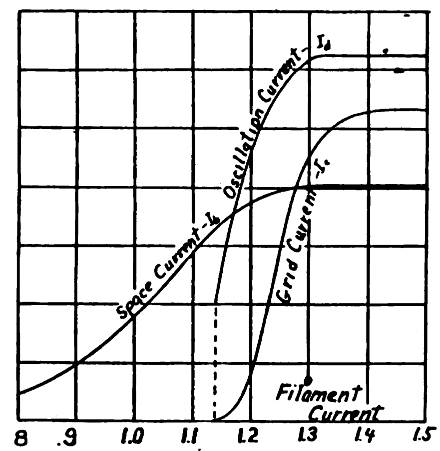

Fig. 57—Oscillator Behavior as a Function of Filament Current

1.15 and flatten off at 1.3 amperes, as shown in Fig. 57. With the average audion, operating at 1.35 amperes, the filament current can vary a considerable amount on either side and not affect the power delivered.

These curves are for a plate voltage of 300. If the voltage is raised, the saturation point is shifted to a higher value. The amount of this shift is not very great however, and as this type of audion is not built to work safely at much over 300 volts, the values given are satisfactory up to 400 volts.

Figs. 58, 59 and 60 show a family of these curves with various values of R_1. The larger values of R_1 cause the curves to flatten out at a lower filament current value thereby allowing satisfactory operation at a lower filament current. The power output, however, is reduced. A compromise must be made, in a given case, between the high current with more power but short life, and lower current with less power and longer life.

The value at which the oscillations start in the average case is 1.15 amperes. It is possible to adjust an

oscillator circuit so that oscillations will begin as far down as 0.95 amperes, but such an adjustment will give neither the maximum power conditions in the proper operating regions nor anywhere near the proper grid current for satisfactory behavior. These curves indicate only the operation around the region of adjustment for greatest power.

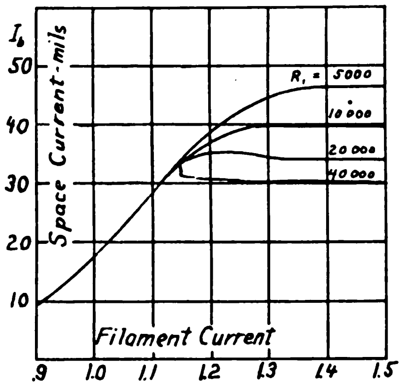

FIG. 58—OSCILLATOR SPACE CURRENT AS A FUNCTION OF FILAMENT CURRENT

Since increasing R_1 makes the flat portion of the oscillation current curve begin at a low value this can be used to counteract the reverse shift caused by raising the plate voltage. The two shifts are such that, by raising both R_1 and the plate voltage the flat part of the curve remains the same, but the power is increased. For greater power, if low filament current and long life is desired, this combination accomplishes the purpose.

28. VARIATION WITH COUPLING

The behavior of the oscillator as influenced by the impedance of the load circuit is shown in Fig. 61. The oscillation current is seen to reach a maximum when the attached impedance is 1800 ohms. The maximum point is not sharply defined. The impedance may be varied between 1000 to 5000 ohms with very little change in power output. The space current, however,

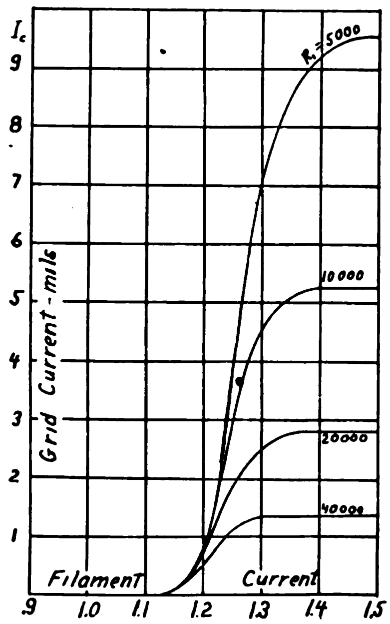

FIG. 59—OSCILLATOR GRID CURRENT AS A FUNCTION OF FILAMENT CURRENT

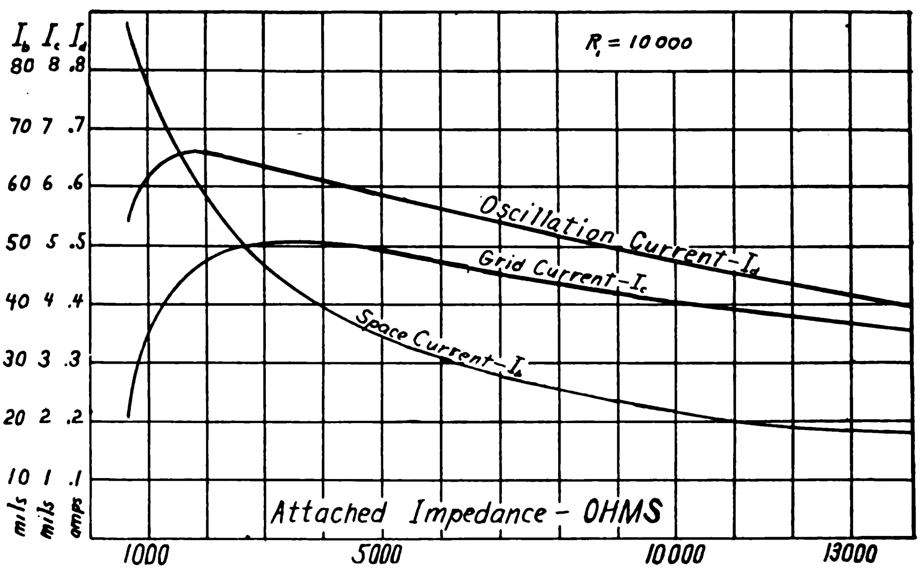

FIG. 61—BEHAVIOR OF AN OSCILLATOR AS A FUNCTION OF PLATE COUPLING. R_1 = 10,000

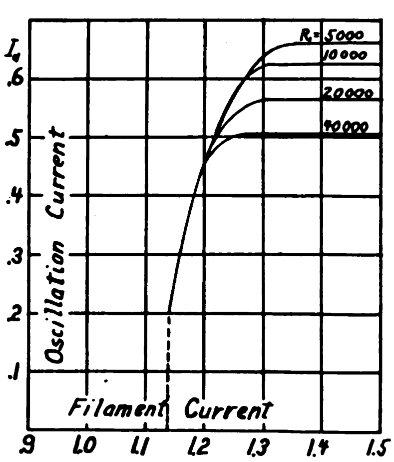

FIG. 60—OSCILLATION CURRENT AS A FUNCTION OF FILAMENT CURRENT

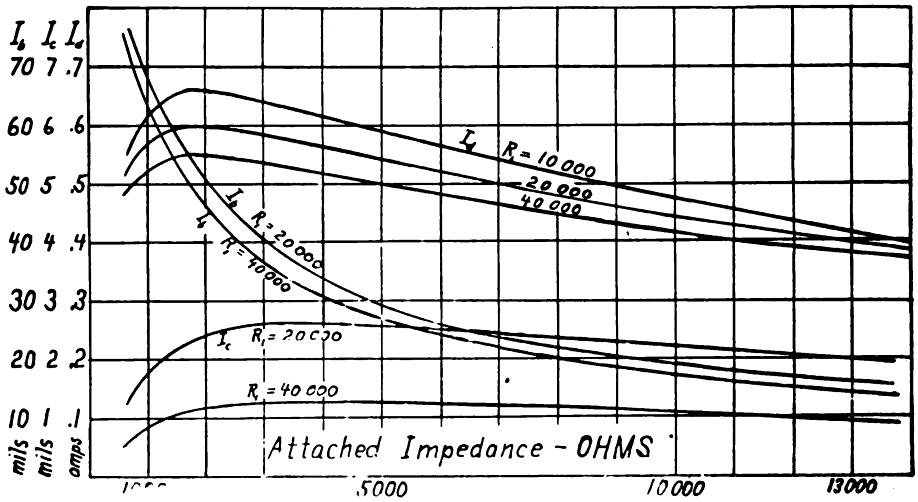

FIG. 62—BEHAVIOR OF AN OSCILLATOR AS A FUNCTION OF PLATE COUPLING AT VARIOUS VALUES OF R_1

decreases rapidly as the impedance increases, and the efficiency increases accordingly. The operation of the audion with an impedance of 3000 to 6000 ohms gives so much better efficiency than is obtained at the point of maximum power that it usually pays to sacrifice the power output to get the efficiency. If the power is needed badly however, raising the plate voltage will bring up the power and yet keep up the efficiency. The practise adopted is therefore to couple closer than

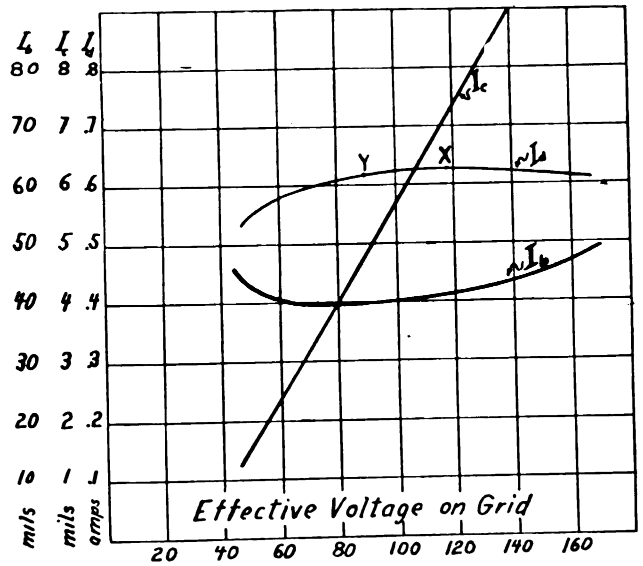

Fig. 63—Effect of Input Voltage on Grid upon Output

is needed to give the maximum of power in order to secure better efficiency.

Curves for other values of R_1 are shown in Fig. 62. They show chiefly a reduction in power, in and out.

29. Variation with Input on Grid

In the writer's mathematical treatment of the oscillator (in course of publication) a curve is plotted showing the boundary conditions between the oscillatory and non-oscillatory states of a circuit where the resistance necessary to stop the oscillations is plotted as a function of the ratio of plate coupling to the sum of plate and grid couplings. There is also made the statement that with the grid coupling (L_g) slightly larger than the plate coupling (L_p) the circuit would continue to oscillate with the greatest amount of resistance, but, that that was not necessarily the condition of maximum power. This agrees entirely with the case of any electrical generator where, if the adjustments are made to take care of the most adverse conditions, under proper normal conditions such an adjustment will not be the best. A principal factor in causing this difference is the absorption of power by the grid. If the grid absorbed no power, and we increased the input alternating voltage upon it, the power delivered would increase, if the current were not striking the top and bottom of the characteristic curve (B and A in Fig. 43), and would remain constant if it were, which latter is the usual case. However, since the raising of the input voltage does produce more rectified current to the grid, there is an increase in the power absorbed and no increase in that delivered. The result is that raising the grid input beyond a certain amount begins to cause a reduction in power in the oscillation circuit. From this consideration alone, we should make the coupling to the grid large enough to secure maximum power and no larger.

A second reason for making a proper adjustment of input to the grid is to prevent its being overheated. The flow of rectified current from the grid to the filament heats the grid sufficiently to weaken it or cause it to emit electrons itself. In the latter case current flows both ways between the grid and filament, absorbs power, overheats the filament, and reduces the rectified current to the grid. A further trouble thus caused is an overheating of the audion without an increase in power. On account of the likelihood of overheating of the grid, no larger grid input should be used than is necessary for maximum power. Fig. 63 gives curves of space, grid, and antenna currents as a function of grid input. The output of maximum power is indicated at X for a grid voltage of 120 volts. However, the point Y is better than X as the output power is almost the same though the plate power is less. The greater efficiency is worth the sacrifice in power, especially as the latter may be compensated for by raising the plate voltage. At the same time, point Y produces a much smaller grid current and the likelihood of overheating of the grid is less.

30. Variation with Antenna Resistance

In a previous section on coupled circuits it was shown that increasing the resistance of the secondary at

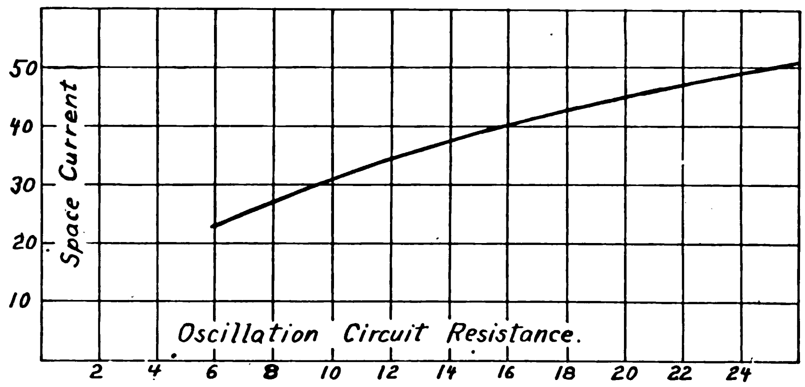

Fig. 64—Effect of Varying Oscillation Circuit Resistance

resonance, reduced the resistance introduced into the primary. In oscillators, reducing the resistance in the oscillation circuit makes the dynamic characteristic curve of the audion and circuit vary in shape, or size, or both. This variation causes an increase in the so called "rectified" current through the audion. In Fig. 64

is shown a curve between antenna resistance and space current. It is not far from a straight line. With high amplification constant audions and certain circuit adjustments (large grid input) a curve is secured which is straight over a considerable portion of its length.

The relation existing between oscillation circuit resistance and space current gives us a very convenient method of measuring antennae capacities and resist-

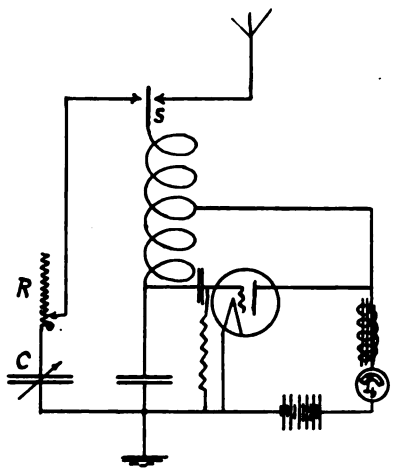

FIG. 65—MEASURING CIRCUIT FOR ANTENNA CONSTANTS

ances. An oscillator is connected to an antenna and adjusted properly at the wave-length at which it is desired to know the effective capacity and resistance. The space current is then noted. The switch S Fig. 65 is then thrown, putting the oscillator onto a dummy antenna whose capacity C is adjusted to give the same wave-length and resistance R to give the same space current. The values of C and R are then the effective

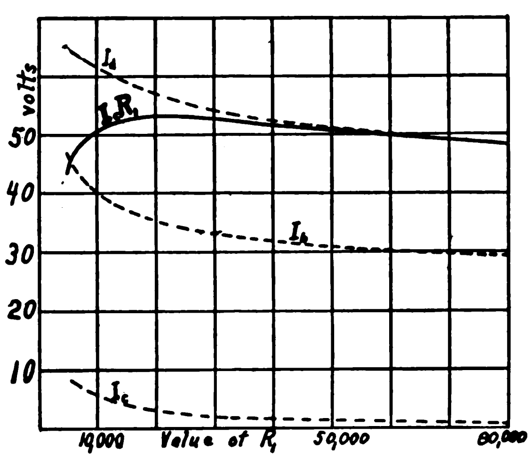

FIG. 66—CONTINUOUS POTENTIAL ON GRID PRODUCED BY I_c THROUGH R_1

capacity and resistance of the antenna at the wave-length in question.

31. VARIATION WITH GRID RESISTANCE

Curves were shown in Fig. 53, and others, showing how varying the grid resistance changed the form of the curves. Fig. 66 shows how the grid resistance affects the space, grid, and antenna currents, all other things being kept constant. In all cases, increasing R_1 reduces them. Fig. 66 also shows the negative potential produced by the grid current $I_c R_1$ as a function of R_1. The potential is nearly constant throughout. It may, however, take an entirely different form as the latter is dependent upon the adjustment of the circuit and the constants of the audion. The curve given is that for the type E audion with the adjustment giving maximum power.

32. EFFICIENCY

By efficiency of an oscillator is meant plate efficiency only—oscillation current power divided by plate power supplied.

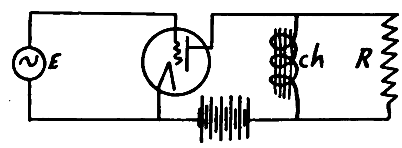

FIG. 67—AUDION WITH LOAD CIRCUIT R AND VARIABLE VOLTAGE INPUT E

The theoretical efficiency of an audion circuit is difficult to determine. It depends too much upon the assumptions as to how it operates. If the circuit is assumed as of the form in Fig. 67, we have the d-c. loss only within the audion, and an a-c. dissipation of power both in the audion and in R. All the direct current passes through the large choke coil and the alternating current through the resistance R. If we assume the space current has the form shown in Fig. 68 consisting of a constant value A and a variable sine wave

$$i = A\,(1 + \sin \omega t) \qquad \textbf{(16)}$$

and assume also that the impedance of the audion is constant, the power out is given by $R\ A^2/2$, and the

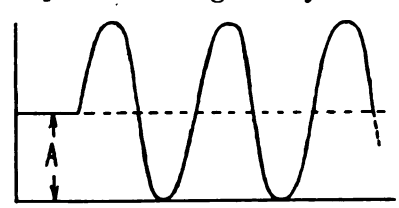

FIG. 68—ASSUMED SPACE CURRENT $i = A\ (1 + \sin \omega t)$

power dissipated, both d-c. and a-c. is given by $A^2 Z_o + Z_o A^2/2$. The efficiency is then

$$e\,f\,f = \frac{\frac{A^2 R}{2}}{Z_o\,(A^2 + A^2/2) + R\,A^2/2} = \frac{R}{3\,Z_o + R} \qquad \textbf{(17)}$$

Theoretically on this assumption we can approach 100 per cent efficiency if R is made large enough, and if $R = Z_o$ the efficiency is 25 per cent. Actually neither is found correct.

If we assume that the resistance of the audion varies between zero and infinity in such a manner as to produce the current mentioned in (**16**) through the audion, the power dissipated in R is $R\ A^2/2$ as all the alternat-

ing current must go through R, and the power supplied is $E\,A\,(1 + \sin w\,t)$ where E is the voltage of the B battery. This integrates over a cycle into $E\,A$. When the audion's resistance is zero the total plate voltage is across R, which gives us the value of E in terms of A and R ($E = A\,R$). The efficiency is then

$$eff = \frac{\frac{A^2 R}{2}}{E\,A} + \frac{\frac{A^2 R}{2}}{A^2 R} = 50 \text{ per cent} \qquad (18)$$

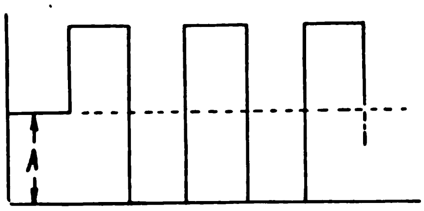

FIG. 69—RECTANGULAR FORM OF ASSUMED SPACE CURRENT

This value is likewise in error as regards the efficiency at maximum power conditions. The audion's resistance does not decrease to zero and the actual efficiency is therefore lower. Experience has shown it to be in the neighborhood of 35 per cent but even then it varies with the type and constants of the audions. It is even possible to secure greater efficiencies than 50 per cent. Using the audion as an amplifier only and taking out power into a tuned circuit has given efficiencies as high as 80 per cent. Using it in oscillators has given efficiencies as high as 70 per cent and there is no reason to suppose that it should be lower than the amplifier value. If the resistance of the audion could be varied between the limits of zero and infinity instantly in a periodic manner a current of the form shown in Fig. 69 would be produced through the audion. With a variable resistance of this kind 100 per cent efficiency would be secured as no power would be lost in the audion. The previous figure of 50 per cent efficiency was based on a zero to infinity variation in resistance, but it varied in such a manner that the resistance was finite for a part of the time producing a sine current, and power was thereby absorbed. In an audion the resistance does not vary between zero and infinity but varies between a finite value and infinity, this tends to make the efficiency lower than 50 per cent. However, it also does not vary in such a manner as to produce a sine current but passes through the intermediate values at a much faster rate than would produce a sine current. This manner of variation approaches the hypothetical variable resistance producing the current in Fig. 69 and tends to make the efficiency approach 100 per cent. The result of the finite limit in resistance in one direction, and the rapid variation through the intermediate values, causes the oscillator to have efficiencies of the order mentioned.

Fig. 70 shows an efficiency curve for an oscillator as a function of plate voltage. The curve shows that efficiencies of over 50 per cent can be secured and that it is still rising, though slowly with plate voltage.

In Fig. 71 is shown a curve of efficiency as a function of attached plate impedance. It shows, as would be expected, that the larger the external impedance, the greater the efficiency. Such a condition is indicated also in Fig. 64 by the rapid drop in space current. The power secured is reduced at the higher values of attached impedance as is the case with any electrical machine under similar conditions. The curve shows a tendency to drop after reaching the value of 9000 ohms but this is due to the reduced power delivered producing a reduced voltage on the grid. A readjustment of the circuit to put the grid input voltage as high at this point as at 2000 ohms, causes the curve to rise and to continue rising until a similar condition occurs again.

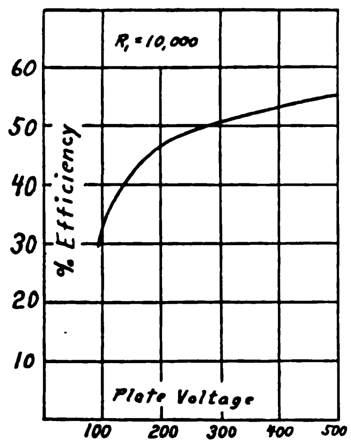

FIG. 70—EFFICIENCY OF AN OSCILLATOR AS A FUNCTION OF PLATE VOLTAGE

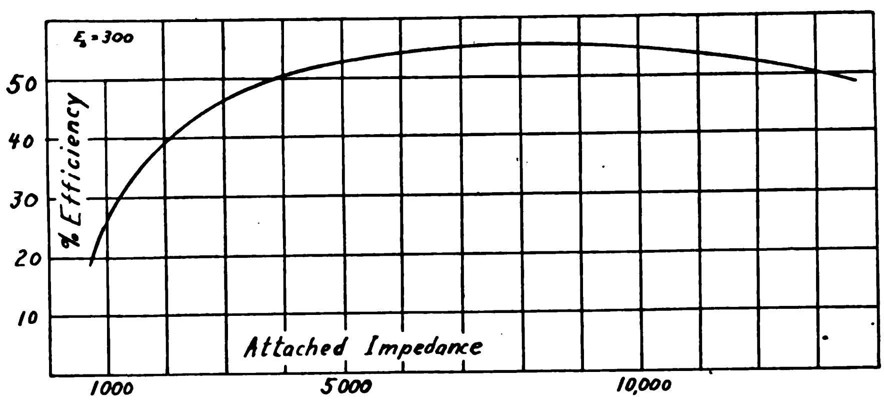

FIG. 71—EFFICIENCY OF AN OSCILLATOR AS A FUNCTION OF PLATE CIRCUIT IMPEDANCE

33. OSCILLATOR ADJUSTMENTS

The adjusting of an oscillator for maximum power is ordinarily a cut and try process. This is especially so if all the independent variables are varied. It is possible, however, to reduce the work to a negligible amount by the adoption of a system based on the curves given. This is accomplished by a systematic assumption of values for a few of the variables, and the

reduction of the final adjustment to the variation of grid and plate coupling. First, then, the filament current should be set. It should be set at the saturation value represented by 1.35 amperes for the *E* type audion in Fig. 57. The grid resistance should next be set at the desired value. This value may be determined from Fig. 72 which gives the power obtainable from this type of audion for various values of grid resistance and plate voltage. The plate voltage should also be determined on. This then reduces the remaining adjustments to two, plate coupling, and grid coupling. The oscillator circuit should be set for the desired wave length and the plate voltage at some value, preferably the value at which the circuit is to operate. From curves in Figs. 53 and 54 find the space and grid currents which should flow at the chosen plate voltage and with the chosen grid resistance. Complete the two remaining adjustments by varying the two couplings—plate and grid, until the space and grid currents so found are secured. The oscillator circuit will then be found to be adjusted for almost maximum power, and good efficiency, as pointed out in the last few paragraphs.

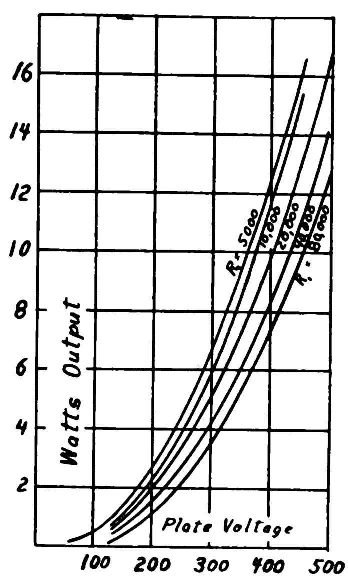

Fig. 72—Power Output of Type *E* Audion

The curves given in these paragraphs apply to the Western Electric Co. *E* type audion. For other types, a complete set must be secured experimentally. Once a set is secured and plotted, the work spent in adjusting circuits is greatly expedited.

34. The Three Adjustments

In any oscillator, either for wireless sets or other purposes, it often becomes necessary to vary the frequency. Such a change in the circuit usually throws out the adjustment. When a set is once constructed the number of adjustments required for such a change is reduced to three. The grid resistance, plate voltage and filament current are already fixed by the construction of the set. The remaining adjustments are frequency, plate coupling and grid coupling. To change the frequency or wave length,

1. Change the oscillation circuit to give the new frequency,
2. Adjust coupling until the grid current is the required value,
3. Adjust coupling until the plate current is the required value.

The second and third adjustments may affect the first a trifle and vice versa so that they should be gone over a second time.

The simple relation connecting grid and space currents with grid and plate couplings, and plate voltage makes the adjustment of an oscillator a much simpler matter than the adjustment of most radio apparatus. There is no adjusting and readjusting for maximum power, nor adjusting and readjusting of the grid input to see its effect on the power, as all these are determined beforehand in the laboratory for a particular type of audion. The manipulation is reduced to two adjustments in addition to that of wave-length, and the proper value of these are determined with a d-c., instead of a hot-wire, ammeter. It makes no difference what type of oscillator circuit is used, or what the frequency of the oscillator is to be; any oscillator adjusted on this principle by means of the space and grid currents will be operating just as efficiently as any other oscillator with the same values of variables—E_b, R_1, I_a, I_b, and I_c It makes no difference whether the antenna circuit has high or low resistance, with these adjustments the same, the audion will deliver just as much power to one oscillation circuit as to the other. If a failure to secure as much power in one case as another occurs, it is because phase displacements in the oscillator are causing it to approach a non-oscillatory point. Such phase displacements are caused by too much leakage reactance, too small values of plate and grid choke coils, or too small values of stopping condensers. If the circuit is proportioned right the above adjustments hold.

35. Adjustments for Multitube Oscillators

When several audions are used in parallel, the adjustment is similar to that for one audion but the grid and space currents are different. The output impedance of several audions in parallel varies inversely as the number and unless a readjustment in coupling is made little change in power occurs. For the determination of values of the circuit constants, grid resistance, space current, grid current, and power, the same curves can be used as for single audions, if proper regard is taken for the connecting of them in parallel. If one audion uses a grid resistance of 10,000 ohms, using two will require 5000, three 3333, four 2500 ohms etc., at which time the space and grid current *per audion* will be the same as for one audion at 10,000 ohms. The power output of the audions in parallel under these

conditions is the same per audion as for one at 10,000 ohms. If the grid resistance for an oscillator with one audion is 10,000 ohms and more audions are put in parallel without changing the grid resistance in an inverse proportion, the power per audion will fall off. Two will not produce twice as much power as one, and three will not produce three times as much power as one. The use of several in parallel requires a change in plate and grid coupling to make the impedances attached to those members vary in the same way. The adjusting

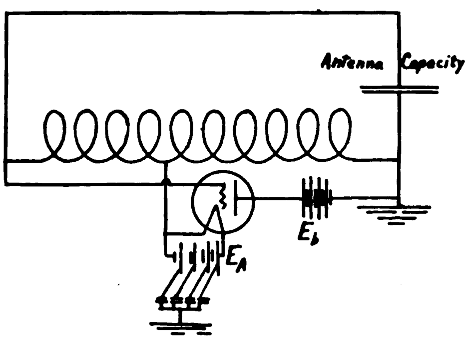

FIG. 73—HOW CAPACITY OF A BATTERY SHUNTS PART OF ANTENNA INDUCTANCE

plate and grid currents *per audion* are to be found from the curves already given Figs. 53 and 54 for the equivalent grid resistance *per audion* in the set.

36. LIMITATIONS IN THE USE OF VARIOUS CIRCUITS

The type of oscillator circuit to be used depends upon the place in which it is to be used. If it is to be used only in the laboratory where all elements of the circuit are under control, the Hartley circuit has many advantages. If it must oscillate into an antenna, the Colpitts or Meissner circuits are preferable. The Hartley cir-

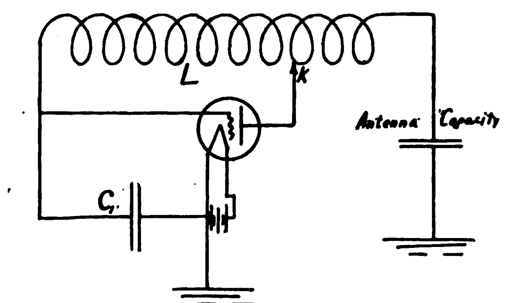

FIG. 74—COLPITTS CIRCUIT CONNECTED TO AN ANTENNA

cuit can have its frequency varied over its entire range by varying the condenser alone, and the other adjustments at all times remain practically constant. This is because the resistance of the fixed inductance rises as the frequency does but the mutual reactance $M\ \omega$ also rises and keeps the attached impedances approximately constant. However the Hartley circuit is unsuited for working into an antenna. In the first place the antenna is the capacity in the oscillation circuit and its effective value increases as the frequency does. The frequency would have to be varied by a series condenser or by decreasing the inductance. The former is undesirable on account of its inefficiency. The latter is all right but necessitates changing couplings. In the second place, one side of the antenna capacity is the ground. Ordinarily the filament supply source for the audion is grounded or has a large capacity to ground and this would produce a troublesome, if not prohibitive, capacity around a part of the antenna inductance see Fig. 73. This could be avoided by connecting choke coils in the filament leads but such coils would be bulky and wasteful of power. The Colpitts circuit avoids this latter trouble since one of the capacities used is the antenna and its ground side is connected to the filament. The filament is then actually grounded and capacity to ground gives no trouble.

The objection to the Colpitts circuit is that it is necessary to change C_1, L, and coupling K Fig. 74 in making a readjustment. Such changes can be made by a gang switch at one operation, in which case the operation of a set is simplified. For actual use on antennae, this circuit has a wider use than any other.

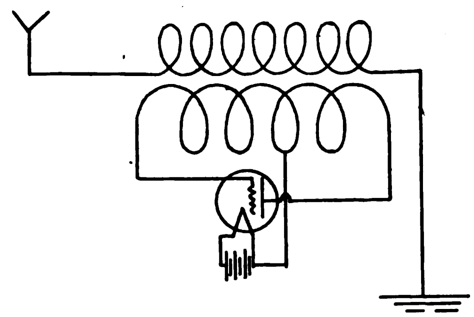

FIG. 75—MEISSNER CIRCUIT CONNECTED TO AN ANTENNA

The Meissner circuit has all the good points of both the previous circuits but it has one bad point. It is shown in Fig. 75 connected to an antenna. This circuit can be adjusted so that varying the antenna inductance alone will carry it over its entire frequency range. The only difficulty is in the proper initial adjustment. The plate-grid capacity together with the coupling coil forms a Hartley type circuit which often produces its own frequency instead of that of the antenna circuit. This can only be avoided by proper proportionment and adjustment.

For very short waves on antennae, the reversed feed-back circuit Fig. 18 is most satisfactory. This circuit cannot be used if the coupling to the plate is of the order of half the total antenna inductance or less. In such cases, a parasitic oscillation is produced due to grid-plate capacity and the attached inductances. For this reason it is non-usable at medium and long wavelengths with the average antenna.

37. CONCLUSION

This paper, it is realized, does not cover the field of the audion oscillator anywhere near completely. To do so would require several times as much space as is

used and would not add important matter in the same proportion. The curves given are for an average audion of a certain type and largely for certain adjustments in the circuit. To cover completely the oscillator's behavior would require many other sets of curves based on other adjustments. Many of these curves would be of entirely different shape and point to entirely different conclusions. However as the oscillator is more important as a generator of high frequency power than as a mere generator of sustained oscillations only the set of curves based upon maximum power has been given.

The use of other makes of audions does not alter the fundamental facts covering the oscillator's behavior. Sets of curves for them will have the same general shapes but of course will give different maxima. Other oscillator circuits may be used but they produce the same curves unless phase displacements are introduced. Such circuits will not deliver the power that proper ones will and they have been omitted.

ALASKA DEVELOPMENT BOARD

Legislation has been drawn up proposing an Alaskan Development Board to be composed of three persons appointed by the President.

The Board is to have all authority now being exercised in Alaska by existing executive departments and commissions, that is—"the Board is to have jurisdiction and control over the care, use and disposition of all reserved and unreserved public lands, including forests and waters and resources therein, . . . mines, minerals and mining." It is to be under the general supervision of the Secretary of Interior and any decision made by the Board may be appealed to the Secretary of Interior.

The members of the Board are to reside and maintain their branch offices in the territory of Alaska. The salary of the chairman is to be $8,500 and the other members are to receive $8,000 annually.

This bill is in line of recent statement of the former Secretary of Interior, Franklin K. Lane, who called attention to the urgent need of such a Board for Alaska.

ELECTRIFICATION OF FIRST MAIN LINE ROAD IN SOUTH AMERICA

A contract amounting to nearly $2,000,000 for the electrification of the first main-line railway in South America has been awarded to the International General Electric Company.

The electrification is over the line of the Paulista Railway Company between Jundiaby and Campinas, Brazil, a distance of 45 kilometers or about 28 miles. But since the road is of double track construction the total mileage, including switches and extra track, amounts to 76 miles.

The equipment to be supplied by the company consists of 12 locomotives, 8 freight and 4 passenger engines, material for the transmission line and substation and a 3000-volt overhead construction of the twentieth century type.

This project anticipates further extensions amounting to 100 additional miles of route which may eventually bring the total electrification up to 128 miles extending between Jundiaby and San Carlos.

Power for the operation of the lines will be supplied by the Sao Paulo Light and Power Company at 88,000 volts, 60 cycles.

The locomotives will be of the geared type, 3000-volt direct current. The freight locomotives will weigh 100 tons each, all weight on driving axles, and the passenger engine 120 tons, equipped with two axle guiding trucks at each end. They will be built at the Erie Works of the General Electric Company. All of them will be equipped with regenerative braking apparatus. The design of the new equipment in fact will parallel closely the Chicago, Milwaukee and St. Paul electrification, while the locomotives will be almost the duplicates of those used so successfully on the Butte, Anaconda & Pacific Railway, except for slightly increased weight and the addition of regenerative braking.

It is expected that the new line will be in operation in July 1921.

MORE SURPLUS WAR EQUIPMENT FOR ROAD CONSTRUCTION

The Post Office appropriation bill carried a provision whereby tractors may be lent by the War Department to the States for use in highway construction. When the conferees finally agreed to this provision the Secretary of War was vested with authority to use his discretion in lending such tractors as could be spared for road construction work. All expenses for repairs and upkeep as well as loading and transportation charges are to be paid by the State.

The Reavis Bill, H.R.13329, is also favorably reported. This provides for transfer of additional machinery and equipment to the Bureau of Public Roads for use in highway construction, and will permit of the use of mobile machine shops and other similar Army equipment by the Bureau of Public Roads. The committee report points out the need for suitable storage facilities for road building equipment, which is to be so used.

The Department is given authority to use its funds to provide these needed storage facilities.

According to reports recently submitted by the Bureau of Roads, this equipment will be very acceptable and will be immediately put to good use.

JOURNAL OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

with which is incorporated the PROCEEDINGS of the A. I. E. E.

PUBLISHED MONTHLY BY THE A. I. E. E.
33 West 39th Street, New York
Under the Direction of the Publication Committee

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

ANNUAL MEETING A. I. E. E. NEW YORK, MAY 21, 1920

Business Meeting

The annual business meeting of the A. I. E. E. will be held in the auditorium of the Engineering Societies Building, New York, on Friday, May 21, 1920, at 8:30 p. m. The Board of Directors will present its annual report for the fiscal year ending April 30, 1920. This report contains a summary of the work of the various committees during the year.

The Committee of Tellers will present its report on the election of officers for the coming administrative year, beginning August 1st.

Edison Medal Presentation

The presentation of the Edison Medal will follow immediately after the business of the annual meeting. The Edison Medal for 1919 was awarded, as announced in the January JOURNAL, to Mr. W. L. R. Emmet "for inventions and developments of electrical apparatus and prime movers." President Calvert Townley will preside at the presentation, the tentative program of which is as follows:

1. The Edison Medal, by Carl Hering, Chairman, Edison Medal Committee.
2. Achievements of W. L. R. Emmet, by Past-President H. W. Buck.
3. Presentation of the Medal, by President Townley.
4. Response, by W. L. R. Emmet.

Ladies are cordially invited to attend this meeting.

PACIFIC COAST CONVENTION

The ninth annual Pacific Coast Convention will be held in Portland, Oregon, July 21-23, 1920, under the auspices of the Portland Section.

The program is not complete as yet. Details as to the papers and authors, entertainment features, etc., will be contained in future issues of the JOURNAL.

Upon recommendation of the Portland Section officers and Vice-President Fisken, the following Pacific Coast Convention Committee has been appointed by President Townley: R. M. Boykin, Chairman, O. B. Coldwell, Wm. J. Cottrell, R. L. Elder, L. G. Fear, Lee W. Going, W. C. Heston, W. F. Hynes, A. H. Kruel, R. F. Monges, A. S. Moody, C. P. Osborne, E. D. Searing, W. S. Turner, Carl L. Wernicke, E. F. Whitney, J. E. Yates, all of Portland; and the following Chairmen of other Sections—H. S. Evans, Denver; Markham Cheever, Salt Lake City; Clem A. Copeland, Los Angeles; R. F. Hayward, Vancouver; G. E. Quinan, Seattle; J. E. E. Royer, Spokane; W. G. Vincent, San Francisco.

INSTITUTE MEETING IN BOSTON

The 359th meeting of the A. I. E. E. was held in Boston, April 9, 1920, and was a joint meeting with the American Electrochemical Society which held its 37th general meeting April 8-10, 1920. The joint meeting on Friday was held at the Copley-Plaza hotel and there were 350 members registered, 150 A. I. E. E. members and 200 A. E. S. members. The Board of Directors of the Institute held its regular monthly meeting, Friday afternoon, April 9, at the Copley-Plaza Hotel, Boston. Present: President Calvert Townley, New York; Vice-President N. A. Carle, Newark, N. J.; Managers, Charles S. Ruffner, Wm. A. Del Mar, L. F. Morehouse, New York, Charles Robbins, Frank D. Newbury, Pittsburgh, E. H. Martindale, Cleveland, Walter A. Hall, West Lynn, L. E. Imlay, Niagara Falls; Secretary F. L. Hutchinson, New York.

Reference to the important matters discussed at this meeting may be found in this and future issues of the JOURNAL under suitable headings.

The first technical session was called to order at 9.30 a. m., President W. D. Bancroft of the A. E. S. presiding. Two papers were presented on behalf of the A. I. E. E. as follows: *Nitrogen Fixation by the Silent Discharge Process*, by C. F. Harding, and *Electric and Magnetic Properties of Iron-Nickel Alloys*, by T. D. Yensen. Thirteen short papers on behalf of the A. E. S. were also presented at this session.

At the invitation of the General Electric Co. a visit was paid to the Lynn works of the company, for which special cars were furnished. A party of 250 made the trip to Lynn where the members in several groups were taken by different routes through the turbine department, motor department, meter and instrument departments. One of the features of interest was an electric furnace in full blast. The party returned to the Copley-Plaza at 5.45 p. m.

At 6.30 p. m. a subscription dinner was served at the Copley-Plaza which was attended by 125 members and guests.

The evening session convened at 8.30 p. m., President Calvert Townley of the A. I. E. E. presiding. The three papers presented on behalf of the A. I. E. E. were as follows: *Power for Electrochemical Plants* by John C. Harper, *Automatic Control of Arc Furnace Electrodes*, by John A. Seede and *Reactors for Electric Furnace Circuits*, by H. H. Winne. The session closed with the presentation and discussion of several papers by the A. E. S.

THE GREENBRIER, AT WHITE SULPHUR SPRINGS, W. VA.

36th A. I. E. E. ANNUAL CONVENTION AT WHITE SULPHUR SPRINGS, W. VA.

The 36th Annual Convention of the American Institute of Electrical Engineers will be held at "The Greenbrier," White Sulphur Springs, W. Va., June 29-July 2, 1920.

In the selection of White Sulphur Springs the Convention Committee believes that it has taken the first step toward making this year's convention one of the most successful of Institute affairs. White Sulphur Springs has a peculiarly attractive environment on the south slope of the Greenbrier Mountains, 2000 feet above sea-level, where it is never hot, even in mid-summer. The Greenbrier itself is a new and magnificent hotel of modern steel construction, absolutely fireproof and is equipped with every convenience. Every room has lavatory and toilet arrangements and is connected with a private bath. For those desiring quiet, there are 60 small cottages surrounding the hotel. Members will find that one of the chief charms of White Sulphur Springs lies in the ability to find things to do. There is an 18-hole golf course, 6250 yards long, one of the finest in the country, and an equally good nine-hole course. The new clay tennis courts are famed the country over. The new bath establishment is luxurious and complete. Every facility is offered guests to enjoy the same kind of baths as are given at European resorts. There is a fully equipped swimming pool, 50 by 100 feet. Over 100 miles of well built track winding in and out through the mountain ridges lead those interested in horses and riding through some of the most beautiful scenery in the State. A fine stable is maintained, with thoroughbred hunters, jumpers, and horses for all occasions and there is a pack of hounds for drag hunts. Those interested in motoring will find the roads leading through White Sulphur Springs in excellent condition and motoring from New York, Philadelphia and Washington is steadily increasing.

In distinction to the Midwinter Convention of the Institute which is almost entirely devoted to the presentation and discussion of technical papers; the Board of Directors in conformity with a policy adopted years ago, that the Annual Convention program should be so arranged as to provide opportunity for those attending to increase their circle of Institute acquaintanship through association in recreation, has requested the Meetings and Papers Committee to confine the technical sessions to the mornings, leaving the afternoons and evenings available for events to be arranged by the Convention Committee, or otherwise as the individual members and guests may desire.

A tentative program has been arranged which will call for the opening of the Convention with the presentation of the President's Address followed by the Technical Committee Reports. Six sessions under the auspices of various technical committees have been mapped out as follows: Electrical Machinery Committee, B. A. Behrend, Chairman, Symposium on "Temperature Conditions Prevailing Inside Large A-C. Generators," with papers by Philip Torchio, B. G. Lamme, W. J. Foster, C. J. Fechheimer and F. D. Newbury, and R. E. Gilman.

Protective Devices Committee, D. W. Roper, Chairman, papers by C. P. Steinmetz, F. H. Kierstead, H. B. Dwight, and B. Gross.

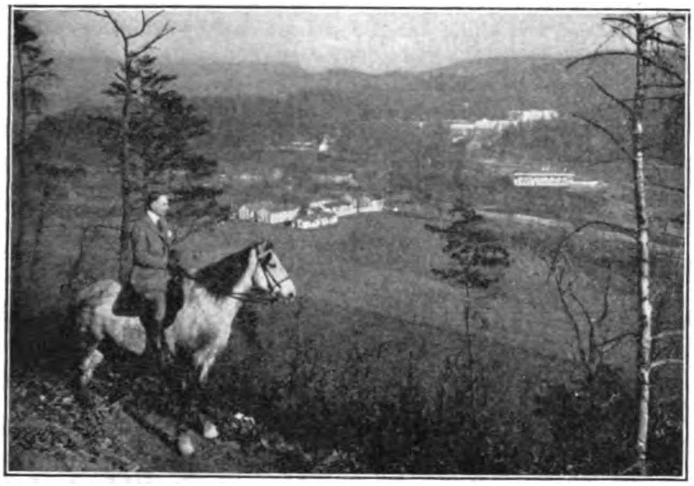
Special Committee on Determination of Power Factor, S. G. Rhodes, Chairman, report of committee and papers by Messrs. Holtz, Brown, Pratt, Silsbee, Wallau, Fortescue and Torchio.

Electrical Machinery Committee, B. A. Behrend, Chairman, session on Welding with papers by Messrs. Hansen, Bergman, Churchward, Candy, Turbayne and Miner.

Power Stations Committee, Philip Torchio, Chairman, Symposium on "Excitation," with papers by Messrs. Bauhan, Ross, Vogel and others.

Miscellaneous session with the following papers; "A-C. Commutator Motors" by J. I. Hull; "High-Tension Insulator Porcelain" by W. D. Peaslee; "Reactive Power and Magnetic Energy" by J. Slepian and "The Corona Voltmeter II.," by J. B. Whitehead and T. Isshiki.

The Convention Committee, appointed by President Townley, and which is charged with the duty of making all necessary arrangements for the convention, in addition to the technical sessions arranged by the meetings and Papers Committee as outlined above, is composed as follows: Messrs. John H. Finney, Washington, D. C. (Chairman), Walter A. Hall, F. L. Hutchinson, Farley Osgood, Chas. Robbins, A. M. Schoen and W. I. Slichter.



A BIRDSEYE VIEW OF THE GOLF LINKS AND THE WHITE SULPHUR SPRINGS RESORT

A complete program will appear in the June JOURNAL giving authors and titles of all papers, details regarding section delegates conferences, entertainment features, hotel and railroad rates, etc. This information will also be mailed to the Institute membership in circular form.

FUTURE SECTIONS MEETINGS

Erie.—May 17, 1920. Professor V. Karapetoff.

Ithaca.—May 21, 1920. Subject: "High Tension Insulators." Speaker: Mr. A. O. Austin, Engineer, with the Ohio Insulator Co.

Milwaukee.—May 19. 1920. Subject: "Coming Science of Acoustical Engineering." Speaker: Professor V. Karapetoff.

Philadelphia.—May 10, 1920. Students' Night. Subject: "Professional and Financial Aspects of Electrical Engineering."

June 7, 1920. Annual Meeting. "Howard McCall Field." A day in the open air; sports.

St. Louis.—May 26, 1920. Mr. Beck, of the Southern Illinois Public Utilities will speak before the Section.

San Francisco.—May 28, 1920. Railway Electrification Committee Report.

Washington.—May 11, 1920. Annual meeting; election of officers.

APPEAL OF AUSTRIAN ENGINEERS

Fellow Craftsmen: Austria is hungry! The supply of foodstuffs available is less than half enough. Hunger has lowered the standard of our work and has undermined us so physically that we can do nothing toward improving ourselves. We turn to America as the only state which can help us in our distress; the only nation in the world that can keep us from starving.

There are 1000 members in our organization in Austria in the various branches of Engineering, such as Electrical, Mechanical, Civil, Mining, Architectural and Chemical. Approximately half of our members are wholly without employment, but even those who have work receive only on an average of 1500 kronen a month, a little more than $5.00.

Through the American Relief Administration a means is provided for furnishing us with food. Americans can buy food drafts at any bank in America and send them to us by registered mail. On presentation of these drafts in Austria the American Relief Administration Warehouse will deliver to us stipulated quantities and kinds of American food shipped to Austria for that purpose. The American Relief Administration has had post cards printed to be sent to relatives and friends in America. These cards tell how you can help us. We guarantee that all food received from food drafts sent to us from America will be distributed equitably among our members under direct supervision of the American Relief Administration representatives in Austria.

You are our professional brothers—and we ask you to stand by us in our hour of need. We appeal to you, fellow craftsmen, across the sea to send us food drafts, lest we starve!

Address:
Gewerkschaft der Ingenieure in Privatdienst,
Wien, VI, Kostlergasse 7, Mezz. links.

April 10, 1920.

Charles F. Rand, Esq.,
71 Broadway,
New York City.

Dear Mr. Rand:

You have, I know, interest in our Food Draft scheme, and I wonder if you can help me out. We find that the needy population in Austria is largely concentrated in Vienna. There are very few Austrians in America who can claim affiliation in the present restricted area of that country, and as a result few Food Drafts are issued in America to friends and relatives. This means that the people are largely dependent upon finding new friends or associations to whom they can appeal. As a result, various associations and societies in Austria are appealing to similar organizations here.

As an instance, the medical men here have banded together to support the medical men in Vienna. The firemen of New York are buying Food Drafts for the firemen of Vienna. The Geological Survey is arranging for the purchase of Food Drafts for the geologists over there, and so on.

Now comes through a letter from the "Society of Engineers in Private Service." This organization includes electrical, mechanical, civil, mining, and mechanical engineers, and architects. These men are in private employ and not in government employ, and are in extremely bad circumstances. They have sent me six copies of a letter which they desire to put into the hands of these various societies here.

Very truly yours,
s/d EDGAR RICKARD,
Acting Chairman,
American Relief Administration.

April 12th, 1920.

Mr. J. Parke Channing,
Chairman, Engineering Council,
61 Broadway, New York.

Dear Sir:—

I wish to give my endorsement of the project of endeavoring to sell food drafts among our engineers for the benefit of the engineers in private practise in Austria.

If you feel willing to add your approval I suggest that you transmit the papers to Mr. Flinn and request him to endeavor to arrange for the publication of this appeal in the monthly journals of the several engineering societies.

Very truly yours,
s/d CHARLES F. RAND,

April 13th, 1920.

Mr. A. D. Flinn, Secretary,
Engineering Council.

I herewith enclose you five identical letters, all originals, from the Austrian "Society of Engineers in Private Service," together with a letter from Edgar Rickard to Mr. Rand, and one from Mr. Rand to me.

It goes without saying that anything of this character which has the endorsement of Mr. Hoover should be given most serious consideration. I am prepared to give my approval to it and I would suggest that you transmit these copies to the Secretaries of our various constituent societies, together with copies of the letters from Messrs. Rickard, Rand and myself.

Yours truly,
s/d J. PARKE CHANNING,
Chairman.

AERONAUTIC CONGRESS, ATLANTIC CITY, N. J., MAY 20-30, 1920

The third Pan-American Aeronautic Congress will be held under the auspices of the Aerial League of America at Atlantic City, N. J., May 20-30, 1920. In connection with the Congress an engineering conference will be held to discuss important phases of aeronautic engineering, including the illumination of airplanes and aviation fields.

A cordial invitation has been extended to the membership of the American Institute of Electrical Engineers to attend this Congress and the engineering conference.

ENGINEERS MEETING IN CHICAGO APRIL 19-20

Some months ago the governing body of the Western Society of Engineers, of Chicago, extended an invitation to the governing bodies of the National Societies of Civil, Mining, Mechanical, and Electrical Engineers to hold a joint meeting in Chicago during the month of April, for the general purpose of discussing the interests of the engineering profession. This plan was carried out and the following brief statement has been received as we are about to go to press:

A dinner to which the engineers of Chicago and their wives were invited, and which was also attended by the members of the governing bodies of the five societies mentioned above, was given at the Hotel La Salle on Monday evening, April 19. Mr. A. Stuart Baldwin, Past President of the Western Society of Engineers, presided; and brief addresses were made by the Presidents of the other four societies, followed by an address on "Efficient Democracy" by Dr. Lynn H. Hough, President, Northwestern University.

On Tuesday, April 20, there was a luncheon at the University Club attended by the members of the governing boards, and the executive committees of the Chicago Sections, of the above named societies.

Both of the joint sessions referred to were exceedingly interesting and profitable to all who attended; and this joint meeting will undoubtedly be of general benefit to the entire engineering profession.

ENGINEERING FOUNDATION BOARD

At a meeting of Engineering Foundation Board held on March 19, 1920, the resignation of Dr. W. F. M. Goss, Chairman of the Board, dated February 14, was accepted with regret and appreciation of his able services. On nomination of the Executive Committee, Charles F. Rand was elected Chairman for the term ending at the annual meeting in February 1921.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

SIXTH MEMBER SOCIETY

The American Railway Engineering Association has accepted an invitation from United Engineering Society to become a member society of Engineering Council. The Association has about 1650 members and its headquarters are at 431 South Dearborn Street, Chicago, Illinois. Its President is Mr. Harry R. Safford, and its Secretary Mr. E. H. Fritch. The excellent technical work done by the committees of this Association in many branches of railroad construction and maintenance are well-known.

The Association has named as its representative upon Engineering Council its President, Mr. Safford, who is a member of the American Society of Civil Engineers and Engineering Institute of Canada. He was recently appointed Assistant to President Hale Holden, of the Chicago, Burlington and Quincy Railroad Company, the Colorado and Southern Railway Company, the Fort Worth and Denver City Railway Company, and The Wichita Valley Railway Company. He was formerly Chief Engineer of the Grand Trunk Railway, and is well known in Canada, as well as in the United States. Following the severance of connection with the Grand Trunk, he became Assistant to the Regional Director, U. S. Railroad Administration, Chicago.

The Societies now represented in Engineering Council have an aggregate membership of 45,000.

KEEPING TAB ON FOREIGN MARKETS OF INTEREST TO ENGINEERS

The Government through its Bureau of Foreign and Domestic Commerce keeps in very close touch with conditions in foreign markets, construction work in foreign countries, and other items which will be of distinct value to American engineers to know about in the conquest that is already well started for world trade.

The Daily Consular and Trade Reports afford a good field for keeping in touch with many items that engineers in the manufacturing, construction and consulting fields will want to know more about. A few of the subjects which have been reported since the first of March are itemized below and in addition to these, a list of foreign trade opportunities touching every field of commerce is maintained in the Department of Commerce and daily supplements to this list are published.

In addition to putting engineers in touch with these reports and the list of foreign trade opportunities, the National Service Department of Engineering Council hopes to be able to build up definite contact with the national engineering organizations similar to Engineering Council or at least functioning in the same field in all important countries. This it is hoped will open much valuable information to American engineers and eventually give foreign engineers the advantage of keeping up with American engineering progress. By this means it is hoped that the engineering profession can be of the greatest service to the country in building up world trade.

World's ocean passenger ships, March 1st. Gasoline Situation in British Isles, March 3rd. Swedish market for telephone apparatus, March 3rd. Market for motor trucks in Canary Islands, March 3rd. Iron and steel industry of Hungary, March 4th. The Belgian steel and metal industry, March 4th. German war industries in peace times, March 4th. Swedish demand for American machinery, March 4th. Machinery trade of the Canary Islands, March 9th. French resources of iron ore, March 9th. Plans for development work in Belgian Kongo, March 9th. Increasing demand for electrical goods in Canada, March 12th. Limited fuel-oil supply in

Argentina, March 16th. British output of iron and steel in 1919, March 17th. Steel situation in Great Britain, March 18th. Italy makes large appropriations for public works in Sardinia, March 18th. Iron and steel situation in Canada, March 18th. Need of railway locomotives in Italy, March 18th. Fuel oil for motive power on French railways, March 20th. Decreased Government stock of metals in Great Britain, March 22nd. The metric system in Belgium, March 23rd. Electrification of South African Railways, March 23rd. Iron and steel development in Brazil, March 24th. Japan's machinery imports, March 26th. Exhibition of American products in Buenos Aires, March 31st. New International chamber of commerce, March 31st. Telephones in Bulgaria, April 6th. Additional refrigerating facilities for Italy, April 6th. Credits necessary in selling machinery to France and Belgium, April 9th.

MAIL TUNNEL SYSTEMS FOR LARGE CITIES

When the Senate and House conferees agreed on the Post Office appropriation bill, it contained a provision for a commission, which is to study among other things, the advisability of establishing a system of tunnels to handle mail in congested centers,—especially in New York City.

The commission is to consist of a chairman and four members of the Committee on the Post Office and Post Roads from both the Senate and the House and a postal expert appointed by the Postmaster-General. This commission is to have authority to appoint an advisory council of seven to be composed of those having special knowledge of the work in hand,—preferably representatives of commercial organizations, and engineers who are acquainted with existing conditions and requirements. Further, the commission is authorized to employ such engineers and special experts as it is deemed necessary to assist in its investigation.

The appointment of the advisory council to this commission is in line with the recommendations that Engineering Council has made to the Post Office Committee of Congress. It is especially fitting that this legislation should carry special provision for the use of engineering opinions in the accomplishment of a joint congressional committee's work.

SENATE PATENT HEARING

Another very satisfactory hearing has been given representatives of Engineering Council's Patent Committee and representatives of the Patent Committee of the National Research Council, this time before the Senate Patent Committee.

Following a statement by Mr. Edwin J. Prindle, chairman of Engineering Council's Patent Committee, concerning the large body of representatives of various organizations present, Senator Morris, Chairman of Patents Committee, asked if there was anyone who appeared in opposition to the Nolan Bill. From among seventy or more representatives present, no word of opposition to the general bill was heard.

The amendment to Section 7 of the bill which provides recoveries for infringement, was contested and through questions asked by the Senate committee, it was brought out that such a provision could not be made to apply to present litigations—in such cases this amendment would be simply an interpretation of existing law.

Every witness whether in favor of the provisions in the amendment or not urged that immediate action be taken on the Nolan Bill as originally written in order that immediate relief could be had in the way of increased force and salaries of the Patent Office. The Senate committee agreed to discuss the effect that the amendment would have with members of the House Patent Committee and to take such action as would insure immediate and favorable final action on the Nolan Bill.

NEW RAILROAD CLASSIFICATION OF SUBORDINATE ENGINEERS

The Interstate Commerce Commission has held lengthy hearings on the classification of engineer assistants in the railroad employ, and as a result has issued regulations classifying subordinate officials as provided in the Transportation Act.

These engineers are grouped into a class as "Engineers of Mechanics." This class includes civil engineers, inferior in rank to engineers of maintenance-of-way, chief engineers or division engineers. It includes draftsmen, engineers on maintenance-of-way work, and other engineers of mechanics, who are not vested with authority to employ, discipline or dismiss subordinates.

Representatives of the American Association of Engineers, whose membership includes many engineers in this class, presented arguments in favor of a separate grouping for subordinate technical engineers. It was shown that twenty thousand technical engineers in the employ of the railroads would be included in such classification, whereas only five per cent of that number are engineers that come within the category of executives. No other class of railroad employees has a more trusted relationship with their companies than do the subordinate engineers, assistant engineers, architects, rodmen, chainmen and draftsmen. Because of the fact that this class of engineers has previously had no classification it has received practically no consideration from the railroads in the point of increases in salary, promotion schedules, etc. For the same reason, also, it has been hard for engineering organizations representing this class to obtain improved conditions.

It will be recalled that the Engineering Council went before the old Board of Wages and Working Conditions under the Railroad Administration to assist in getting a classification and increased compensation for the men who have now been classed "Engineers of Mechanics." Some good was accomplished but conclusive results could not be obtained because this group of engineers was not then known as a unit on the Railroads.

CLASSIFICATION AND COMPENSATION OF ENGINEERS

Arthur S. Tuttle, chairman in an address before the American Association of Engineers, Chicago, discussed the work done by the Committee on Classification and Compensation of Engineers. Extracts from his remarks follow, which will add to the records of this activity of Engineering Council that have been printed in preceding issues of the JOURNAL:

A little over three years ago a general investigation of engineering compensation was completed by the American Society of Civil Engineers, from the report of which it appeared that compensation for engineering service compared favorably with that in other professions. Subsequent rapid decrease in the value of the dollar and corresponding lowering of morale led Engineering Council about a year ago to study those branches where compensation was admittedly lowest and where the needs were more pronounced.

A committee was appointed, which held its first meeting April 24, 1919 and to the close of the year the investigation drew heavily upon the time of those engaged in the study. To establish a basis of comparison, to the end that all engineers could be measured as to responsibility on a common basis, a general classification was attempted. A comprehensive nomenclature for service grades was unanimously agreed upon by the Committee and adopted by Engineering Council December 18, 1919; also a further recommendation that this classification be recommended for general use in every branch of the profession. Under it engineering service is to be separated into Professional and Sub-Professional, the former comprising five grades and the latter three, to include in the former only men holding a professional degree or men who have had four years' experience in the Sub-Professional service and who have supplemented this

experience by mastering engineering principles and equipping themselves with the basic essentials for advancing through higher grades. It is also proposed to require education equivalent at least to graduation from a high school for admission to the Sub-Professional service, thus insuring that those who enter it possess the essentials on which to build their further training, and also clearly separating this service from the labor class and placing it unmistakably on a higher plane.

Heretofore efforts in the direction of securing adequate compensation have been handicapped in part by the absence of any well-defined basis for comparison of positions and in part by the unwillingness of engineers to discuss this subject publicly lest such discussion might tend to lower professional pride and dignity. The financial advantages to the capitalistic class through the shortages growing out of the great war and the success of labor in its vigorous efforts to share in these benefits have apparently led engineers to substitute for "the Lord will provide" as an accepted theory a belief that "God helps those who help themselves."

Previous inquiries have been addressed to the individual directly concerned, which involved the collection of a vast mass of data colored by the personality of each respondent. The magnitude of the field, the need for haste, and the desire to get the best valuation available, led the Committee to seek returns from responsible service heads. The advantages of the adopted plan seemed so obvious that the general character of the questionnaire was never made the subject of other than brief discussion. The investigation included the securing of data as to compensation for July 1, 1915 and of July 1, 1919, the former date marking the beginning of the rise in wholesale prices of commodities in common use.

The State and Municipal inquiry was directed to State Engineers, State Highway Engineers, Chief Engineers of State Commissions charged with large engineering undertakings, and City Engineers of the 69 cities having a population of over 100,000. In all 191 services were approached; from 101 of these, returns were received. The entire returns included 2,222 men in State and 3,317 in City service. It is estimated that the sereturns comprise over one-half of the engineers in State service and about two-thirds of those serving municipalities.

Comparing the position returns for the Municipal service with those for this service as a whole, it appears that about 6 per cent of the increased compensation reported has been an incident growing out of promotion to higher grade, which would seem reasonable under normal conditions.

The average age of men in all grades of the State service is much lower than in the corresponding grades of Municipal service, this being probably due in part to the fact that many State services have been organized at recent dates. It also shows that average present compensation for the higher professional grades in Municipal service is much above that in the State service, as is the compensation recommended, and that the present as well as the recommended rates for the lower grades are generally much alike in both services.

Considering the average present compensation reported for the various positions, in the professional service, (these comprising 86 per cent of the total number of engineers concerning whom data have been obtained) the average compensation is less than $2,200, or the estimated cost of living for a moderately small family, and the average compensation for even the highest grades is utterly incommensurate with what might reasonably be expected, particularly when compared with rates generally charged by engineers not in public service.

From the latest statistics available it seems probable that the cost of living is about 80 per cent more than in 1915. This, however, is not to be regarded as the basis for the recommendations of the Committee, which are intended to insure to the young unmarried man an income sufficient on which to live, and to provide compensation for men in the higher grades sufficient not only to make up the increased cost of necessaries, but also designed to provide for recognition of value not heretofore given. It is conceded that men drawing the major salaries should be the ones to make the sacrifices required to meet the war expense. An argument for increasing their pay in the same or greater proportion as for the men living on the lowest living wage would be fallacious if based on the decreasing value of the dollar. In this case the advance proposed is on the ground that it gives the engineer that to which he is entitled but which has heretofore been withheld. By increasing at the top the way will be automatically opened for extending recognition to all grades. Only by such recognition can real relief come to those who have devoted themselves to professional service and who, by reason of the limitation of room, cannot find a place at the very top, but who by proven worth have demonstrated their value and their fitness to assume the large responsibilities placed on them.

The needs of the lower grades of service have now been met to some extent, and if the profession as a whole could unite in a movement to endorse every effort put forth to raise the compensation of chief engineers, the remainder of the problem would be easy to solve. To secure permanent improvement and attract to and retain in the profession the best men, it is desirable to fix pay at entrance at a rate such as not to bring in men who are without engineering education or who have no natural leaning along engineering lines. Men admitted to the service should be denied advance unless decided merit is shown, in which case promotion should be certain and liberal. In this way standards can be raised and the mediocre men will not remain as a handicap to the progress of those more worthy. Before engineers can reach the very highest places in administrative work, they must cultivate an increased breadth of view and accept more responsibility; they must give the business side of undertakings with which they are connected the same thought that they devote to the technical features.

While the suggested increases in compensation would apparently aggregate a vast sum, it is the belief of Engineering Council's Committee that the increase would be more apparent than real as it seems safe to assume that through a restoration of morale with consequent increase in efficiency, through the weeding out of incompetents, and through the certain saving resulting from better design and construction, the total expense would be less than under present conditions.

It cannot be questioned that the long period of comparative inactivity in railroad construction and the return of the roads to their owners must be followed by a revival of enterprises of vast magnitude. The comparative freedom from governmental red tape which will now be enjoyed should open up a brilliant prospect to men in this service, and the speaker sincerely trusts that in the new era about to dawn his professional brethren who have in the past devoted themselves to this branch of engineering will realize their long deferred hopes for the day when members of this profession will find a proper financial reward for their services.

CURRENT ENGINEERING TOPICS

A SUBSTITUTE FOR THE METRIC SYSTEM

A measure providing decimal divisions of the English system of weights and measures has been introduced as a substitute for the proposed compulsory metric system. Advocates of this substituted measure claim that it affords all the advantages of decimal notation, which they claim to bethe only merit of the metric system, and at the same time preserves the convenience, facility and utility which are inseparable from the accustomed measures of length and weight in this country. All that is claimed for this bill is that it will tend to help in the improvement and development of our present system. Engineers who considered this new legislation are of the opinion that it would only

complicate the present usage of our divisions of weights, measures and coins without adding materially to the improvement of our present system.

WATER POWER BILL

The Water Power Bill conferees have reached agreement on all points of difference except the provision limiting certain allowances for severance damages on recapture of franchise at end of the fifty year period. The Senate has receded from its amendment directing the assignment of an army engineer as secretary of the Commission and has left this appointment to the discretion of the Commission.

WAR MINERALS—COURT OF CLAIMS

When it became apparent that the new War Minerals Relief Bill would have the opposition of Congressional leaders, the chairman of the House Committee on Mines and Mining decided to make substantial changes in the measure. The Committee on Rules will be asked to give the new bill a special place on the calendar.

Congressional leaders are trying to cut Governmental expenses in every way possible and they realize that the provision giving authority to the Court of Claims to hear war mineral cases "de novo" would entail large additional expenses over a long period.

Under the provisions of the new bill, however, these conditions are made worse, because it provides that claimants shall have the right of appeal from the Court of Claims through the Supreme Court of the United States. It also relieves claimants from the obligation to execute a bond to protect the Government against reduction by the Court of Claims of any award which may have been already made. In other words, it permits a claimant to accept whatever award the Commission shall recommend, and, without more than nominal cost to himself, appeal to the Court of Claims for more. Also, to guard against the Court of Claims requiring that the ordinary rules of evidence shall apply, it provides that the testimony already taken before the Commission may be used. The Commission has been very liberal in acceptance of testimony from claimants, much of which would not be admitted in a court of law.

To protect against such contingency, the above clause is added. It is easily to be seen that the proposed plan will offer fine business for claim attorneys but indefinitely prolong final settlement.

From the engineer's standpoint, it becomes evident that the bill in the new form will cost the Government a great deal more for its administration, as well as materially extend the time for final settlements.

PERSONAL

H. G. Harvey has resigned as Commercial Engineer of the Nassau Lt. & Pr. Co. of Mineola, N. Y., to take up similar work with the Pennsylvania Utilities of Easton, Pa.

Taliaferro Milton, formerly assistant manager of the Chicago Office of the Electric Storage Battery Company, has become manager of the same office, located at 613 Marquette Building, Chicago.

Geo. C. James, formerly of the Engineering Staff of the Habirshaw Electric Cable Company, Inc., is now connected with Chas. C. James & Company, Stock Brokers with offices at 410 Times Building, New York City.

Ralph A. Watson has left the Consolidated Arizona Smelting Company to become Chief Engineer for the Tennessee Copper Company at Copperhill, Tenn.

J. A. Obermaier, of the Illinois Testing Laboratories, Inc., announces that these laboratories have moved into new and enlarged quarters at 430 South Green Street, Chicago. Here they will be in a position to increase the scope of their work, particularly along the lines of developing new apparatus and doing an increased amount of testing and engineering work.

Henry Harvie has resigned his position as assistant to the hydraulic engineer of design, Hydroelectric Power Commission of Ontario, on appointment to hydraulic engineer with the Canadian Ingersoll-Rand Company, 260 St. James Street, Montreal, Canada.

Wm. C. Rommel, formerly rate expert for the Public Service Commission of Pennsylvania, is now in charge of an office in Harrisburg, Pa., opened by the Utilities Engineering and Accounting Company. The scope of the office will include costs analyzed, rates designed, tariffs prepared for filing, valuations, reports, accounting, engineering, and management.

J. Harvey McClure, formerly general superintendent of the Citizens Traction Company, Oil City, Pa., under the management of Day and Zimmerman, Inc., Philadelphia, has been promoted by that company to the position of vice-president in charge of operation of the Ohio Electric Railway Company. This opens a large field of operations to Mr. McClure, the system having both interurban and city service in Ohio and Indiana. He has made Lima, Ohio, his headquarters. Mr. McClure joined the Institute as a Member in 1919.

W. A. Lodge, research engineer with the Bussman Mfg. Company, will be in full charge of the engineering department, devoting his time to research and the technical development of the Bus Fuse. He will also conduct the necessary tests as required by the Underwriters' Laboratories. Mr. Lodge has for the past four years been with the Underwriters' Laboratories of Chicago as research engineer. Previous to his connection with the Underwriters' Laboratories, he was professor of Electrical Engineering in two of the largest Universities in the United States and Canada.

Theo. Schou, formerly professor of Electrical Engineering at the University of Iowa, and later consulting engineer for the Electric Machinery Company, Minneapolis, Minn., is now connected with the Ideal Electric & Mfg. Co., Mansfield, Ohio, in the capacity of chief engineer. Mr. Schou has specialized in the design of synchronous motors, being recognized as one of the foremost in this field, and will develop a new line of synchronous machines for The Ideal Electric & Mfg. Co., who are enlarging their facilities to include the manufacture of this type of apparatus. During the past few years Mr. Schou has contributed a number of articles on the design and manufacture of synchronous machines to the leading technical periodicals.

W. G. Claytor has been appointed assistant to the general manager of the Roanoke Railway and Electric Company, Roanoke, Virginia, and the Lynchburg Traction and Light Company, Lynchburg, Virginia. Mr. Claytor was formerly general superintendent of the Lighting and Power Departments of the Roanoke Railway and Electric Company and the Lighting and Power and Gas Departments of The Lynchburg Traction and Light Company, having entered the services of these companies in January 1907. He was commissioned a Captain in the U. S. Army in 1918, and assigned to the Construction Division as Electrical Engineer for the U. S. Picric Acid Company, Brunswick, Georgia.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

LEADER FOR ELECTRICAL DESIGNING squad of a very old, large and reputable engineering company. Must have experience in designing electrical installations for industrial plants including power and light wiring; installation of motors, telephone, auto fire alarms, auto call systems, etc., and electrical generating plants. Location New York City. Z-1046.

ELECTRICAL ENGINEER technical man, with broad experience in the design and installation or operation of High Voltage Distribution Systems and Out-Door Sub-Stations. A good position for high grade man with well established progressive company manufacturing high voltage equipment. Give full information regarding education, experience and past connections, as well as salary expected. Location Chicago, Ill. Z-1060.

RECENTLY ORGANIZED FIRM of consulting engineers would like to hear from a graduate designing engineer who has had two or more years experience in the designing of automotive vehicles, preferably tractors or trucks. Prefer applicants who have also had machine shop experience. This opening is an exceptional opportunity for a young engineer who is willing to bend his back over the drawing board when necessary and who has a good personality. An opportunity will be offered to expand into the business end of our work. Applicant must be a natural mechanic and rapid at drafting. Location Wisconsin. Z-1061.

GRADUATE ELECTRICAL ENGINEERS for radio research work. Recent graduate will be considered. Z-1062.

RECENT GRADUATES in Electrical Engineering for our engineering sales department. Write, stating age, experience, salary expected. Communications held confidential. This is an excellent opportunity to gain a broad engineering training in a live organization. Location Rochester, New York, Z-1063.

INSTRUCTORS. An examination will be held in Sampson Hall, U. S. Naval Academy, Annapolis, Maryland, for selection of two instructors in Department of Electrical Engineering and Physics. Examination will be competitive, and candidates found qualified will be eligible in the order of merit as determined by the Board of Examiners, for appointment to fill vacancies in this department. Should more qualify than there are vacancies for at present, their names will be placed on a reserve list for later appointment to subsequent vacancies if they so desire. Appointments will be made immediately to those qualifying for the above vacancies and will thereafter be renewed annually on July 1st, provided performance of duties has been satisfactory. Salary on original appointment is $2000 and an increase of $100 is given on each reappointment. Instructors are eligible for appointment as Assistant Professors, salary $2400, after 2 years, and as Associate Professors, salary $3000 after 5 years. Appointment to Professor after 10 years, salary $3600, with 10% increase every 5 years. Candidates must be American Citizens. The age limits are 25 to 35 years though these may be waived in special cases. Candidates must have completed satisfactory professional courses in recognized colleges or universities. In grading the candidates due weight will be given to past experience, letters of recommendation, etc. The examination will be written and will cover the following subjects: (1) First year College Chemistry; (2) Elementary and Advanced Physics. (More particularly those subjects pertaining to Electrical Engineering); (3) Laboratory work to correspond to (1) and (2); (4) Principles of Direct and Alternating Current Electricity, including storage batteries, direct and alternating current machinery, elementary telephony and radio telegraphy. Blank form of application is enclosed herewith which must be filled out and returned to the Superintendent. U. S. Naval Academy, Annapolis, Md. without delay. Candidates having filled out and returned their form of application may appear before the Board of Examiners on the date above stated, without further authority. It is requested that they bring their references with them. The examination will take about 2 days. Further information furnished on application. A. H. Scales, Captain U. S. Navy. Superintendent. Z-1064.

ELEVATOR ENGINEER. Technical graduate with several years experience in elevator work. Location Pennsylvania. Z-1065.

DRAFTSMEN (ELECTRICAL) FOR PANAMA CANAL: 1 experienced underground power distribution and building illumination; 1 hydro-electric power plant designer; 1 familiar with fire control work of coast artillery, 1 marine Machinery Draftsman. Applicants must be thoroughly experienced in special lines above indicated. American citizens (final papers) under 50 years of age, in good health. Free Steamship transportation from New York or New Orleans, salary beginning date of sailing. No civil service examination required. Write Chief of Office, The Panama Canal, Washington, D. C. Z-1066.

ASSISTANT ELECTRICAL ENGINEER. Public utility located in the Middle West, furnishing electric light, power and railway service, desires a technical graduate, having had practical experience in transmission, distribution and substation work. Ability, personality and enthusiasm such as to qualify applicant for advancement in rapidly growing organization are absolutely essential. Initial salary $3000. Z-1067.

ASSISTANT ENGINEER with experience in transmission and differential work for position with company manufacturing automobile gears. Must be thoroughly familiar both with production, manufacture, and operation. Salary $250-300 per month. Location Ontario. ½ hour from Buffalo. Z-77.

YOUNG ILLUMINATING ENGINEER capable of designing show window and commercial lighting installations; selling experience desirable but by no means essential since the man selected to do designing will be assisted by competent commercial lighting salesmen. Location Tennessee. Z-260.

SERVICES OF TWO YOUNG ELECTRICAL ENGINEERS wanted, recent technical graduate preferred, for A. C. industrial control design. Splendid opportunity. Write stating education, age, nationality, salary and when available. Location Newark, N. J. Z-342.

ELECTRICAL DRAFTSMEN at starting rate of $150 to $175 per month. Duties of position involve designing and detailing in connection the planning of electrical installations in stations and substations. Location Chicago, Ill. Z-548.

INSPECTOR OF MATERIAL for service in the United States. Must be technical graduate with at least two years' experience with large manufacturing concern. Salary $150 a month plus $20 a month Congressional bonus after thirty days' satisfactory service. Applicants should write to Chief of Office, the Panama Canal, Washington, D. C. Z-609.

ELECTRICAL DRAFTSMEN and Designers for work in connection with transmission lines, substation equipment, switchboards, motor control equipment, etc. Location Ohio. Z-613.

LARGE NEW ENGLAND MANUFACTURER of electrical apparatus wants young men with some experience in drafting who desire to improve their opportunities. To such as have good high school education and some technical training but who for some reason were not able to complete their technical course, we offer opportunity to work as draftsmen

at good wages and at the same time, without expense attend courses of instruction to prepare them for positions here as calculators or designers of electrical apparatus or specialists in sales organization. Location Mass. Z-628.

EXPERIENCED SWITCHBOARD OPERATOR for hydro-electric station. Salary $115 per month, eight hours, location New England. Give experience, age, references, whether married or single. Z-678.

SALES ENGINEER; technical graduate preferred but not essential, familiar with Eastern Territory; must have experience in sale of power transmission apparatus and be familiar with factory conditions. Liberal salary and splendid opportunity to connect with a growing concern. Territory New York and New England. Z-772.

ASSISTANT ELECTRICAL ENGINEER for large manufacturer of excavating machinery. Duties will include application and arrangement of electrical equipment, such as—motors, magnetic control, transformers, motor generator sets, wiring, etc. to electric shovels, dragline excavators and dredges. Technical man with electrical and mechanical experience desired. Salary $125-175. Z-817.

ELECTRICAL ENGINEER; permanent position open for graduate engineer, preferably Canadian familiar with Ontario. Intimate knowledge of interurban electrical railway equipment and operation essential. Apply Employees Relations Department, Hydro-Electric Power Commission of Ontario, 190 University Avenue, Toronto, Canada. Z-818.

INDUSTRIAL POWER SALESMEN AND INDUSTRIAL HEATING ENGINEER; capable of assuming direct charge of district in the city of St. Louis and in that district, conducting all negotiations incident to sale of power in large blocks to new industries and conversion to Central Station energy of any isolated plants, now in existence. Men should be able to handle such negotiations with minimum of supervision. They should be graduate electrical engineers. Those having sales experience in Industrial power work are preferred. Location Missouri. New York interview possible. Z-864.

FOREMAN for testing department for magnetos and magneto generators. Department has 25-30 men. Location Brooklyn, N. Y. Z-871.

ILLUMINATING ENGINEER experienced for field work. Must have been doing this kind of work. Location New Jersey. Z-872.

DRAFTSMAN (ELECTRICAL). Must be technical school graduate with at least 3 years drafting room experience and capable of handling the electrical design work on steam or hydro electric stations and high or low tension substations. DRAFTSMAN (ELECTRICAL)—B. Must have had at least 2 years drafting room experience in underground power distribution and building illumination. DRAFTSMAN (MARINE MACHINERY)—C. Must have had experience in theoretical and practical engine, boiler and propeller design and construction of laying out and installing all types of piping systems and auxiliary machinery. Credit will be given for a knowledge of internal combustion and turbine machinery. Applicants should indicate the minimum salary which they would accept, bearing in mind that free furnished bachelor quarters are supplied on the Isthmus, and meals can be obtained at the Government restaurants at about 40c. each and upward. Z-878 A-B-C.

LUBRICATION ENGINEER for the Philippines: must be able to speak Spanish fluently and must be experienced as there is no time for instruction. Salary $3000 and traveling expenses. Location Philippines. Z-901.

POWER HOUSE DESIGNING DRAFTSMAN at the Muscle Shoals hydro-electric power development. Salary not stated. Location Alabama. Z-909.

ELECTRICAL ENGINEER for designing power plants, telephone systems, etc. Location New York City. Z-912.

DEVELOPMENT WORK of Tungsten products pertaining to manufacturing of filament for incandescent lamps. Recent graduate or undergraduate could qualify. Location Bloomfield, N. J. Z-919.

SALES ENGINEER who has had a commercial experience. Must have the commercial rather than the engineering viewpoint. A young man ambitious, enthusiastic, steady and stable, unquestionably loyal, a good letter writer, having a good conception of what is needed to write advertisements for engineering products. Location New York City. Z-932.

YOUNG MAN preferably just out of school to act as clerk, at steel plant. Prefer man with some electrical, technical education, who is looking for some good practical experience along the electrical lines in a steel plant. The work at present will consist of keeping office records, doing some test work, and probably some per month, and should offer an exceptional opportunity for advancement to the right man. Location Delaware. Z-934.

ENGINEER with broad experience in illumination field, should be posted on development of methods of illumination measurements and design of apparatus for such measurements, the direction of special illumination testing, the design of units, the selection of lamps for special work such as is encountered in various signal systems, development of home and farm lighting outfits. Location Northern New Jersey, near New York. Z-940.

MECHANICAL AND ELECTRICAL ENGINEER with several years experience to be the head of a power and machine shop department. Location Massachusetts. Z-941.

ASSISTANT EDITOR. Engineer familiar with gas engines and if possible some garage or automobile work. College graduate with one or two years experience preferred. Services not required until first or middle part of June. Excellent opportunity for advancement. Z-953.

ELECTRICAL DRAFTSMAN to act as designer and squad leader. Must be experienced in layout and design of generating stations and substations. Location New York City. Opportunity for advancement. Appointment must be made by letter stating salary expected and experience. Location New York City. Z-955.

SENIOR PROFESSOR OF MECHANICAL DRAWING (A) SENIOR PROFESSOR OF MECHANIC, desirable that he have practical and commercial experience. (C) ASSISTANT PROFESSOR IN ELECTRICAL ENGINEERING. Location South. Z-956.

INSTRUCTORS, 1000 men for army vocational schools. Mechanical and other subjects such as, auto repair, moving picture operation, machine shop practise, bookkeeping, etc. Civil Service entrance examinations. Location Army camps and posts. Z-961.

MECHANICAL DRAFTSMAN experience in smelting and metallurgical work desirable, or general experience in structural work and machine design will be considered. Knowledge of Spanish desirable but not essential. Z-977.

ASSISTANT PROFESSOR OF ELECTRICAL ENGINEERING. The man for this position must be qualified to teach the fundamentals of Direct and Alternating current theory, and to take charge of a class in Elementary Design. We would prefer a man who has had some experience in special electrical design such as Electrical Railways and Radio work. We would however emphasize the value of his teaching experience above his special work in application. Salary would be $2500. Location Ohio. Z-980.

INSTRUCTORS IN ELECTRICAL ENGINEERING. We shall need two men as instructors in Electrical Engineering. These men should be qualified to handle classes in Electrical Laboratory. They would be more valuable to us if they are able to take charge of class room work for Junior nonelectrical students. This position will pay from $1600 to $2000, depending on the experience of the man. Location Ohio. Z-981.

YOUNG CONSTRUCTION ENGINEER (A) with western mining and smelter experience if possible for work in Peru. SWITCHBOARD OPERATOR (B) must have experience in hydro-electric work. SHIFT BOSS (C) experienced in hard rock ground and square set timber. Must be used to handling Spanish labor. Unmarried men preferred for all of these positions, or married men who are willing to go without family and send for them later. Spanish essential. Only engineers used to working in high altitude will be accepted. Transportation and lodging furnished. Board $25 per month. Z-994-A-C-B.

ELECTRICAL ENGINEER for laboratory testing of raw material to finished product. Will also be in charge of about 20 men. Location Yonkers, New York. Z-998.

ELECTRICAL ENGINEER for efficiency tests and for general electrical testing on all kinds of motors and electrically heated ovens. Recent graduates considered. Location Tarrytown, New York. Z-1007.

INSTRUCTOR to teach elementary mathematics and mechanical drawing in Apprenticeship School. Candidates should have had some technical training and shop experience and should understand the handling of young men. This position offers excellent opportunities for advancement in the Works through one of its many departments. Location Connecticut. Z-1012.

MAN to take up work in the laboratory of a large Electrical Manufacturing and Sterilizer Equipment Company. This work will have to do with electrical and chemical experiments and it would seem that a young man probably a college graduate in Electrical Engineering, would be most suitable. Location New Jersey. Z-1014.

MECHANICAL ENGINEER to take charge of machinery for the

treatment of Asbestos fiber. Must be thoroughly proficient mechanical engineer, with good knowledge of electrical power. Must also be good executive. Location New York City. Z-1015.

ASSISTANT SUPERINTENDENT OF ELECTRICAL DEPARTMENT. Technical graduate with some experience in electrical construction work. Duties would consist of drafting office work and outside construction supervision. Must also be able to assist in systematizing department employing about 30 men. Z-1079.

ELECTRICAL ENGINEER (A) with 3 or more years teaching experience, desiring to make change to electrical machine design work wanted, to take up interesting line of alternating current development. Splendid opportunity for man of ability and energy to make permanent connection. ENGINEER (B) with technical training, experienced in design of alternating current motors to take up development of adjustable and varying speed alternating current equipment. Permanent position with good opportunities for growth. TECHNICALLY TRAINED ENGINEER (C) with railway operating experience, desiring to make change to design work, wanted for development work connected with railway electrification. Permanent position for man of ability. Z-1093 A-B-C.

MEN AVAILABLE

ELECTRICAL ENGINEERING GRADUATE: energetic and ambitious desires position in engineering department of firm where he is given an opportunity to advance according to ability shown. Power plant and substation work preferred. Have had two years drafting experience. Location desired Chicago. E-2142.

ELECTRICAL ENGINEER: University graduate, twelve years varied experience, electrical, mechanical, steam and hydraulic, with mining, industrial and hydro-electric companies in field and office; design, construction, maintenance, operation; good organizer. Age 34, salary $300. Available about June 1st. E-2143.

ELECTRICAL ENGINEER: desires position in consulting or industrial line. Over five years experience with leading electrical manufacturer. Shop testing, railway equipment installation and industrial equipment installation comprise part of practical experience. Over three years railway application engineer, handling substations distribution systems, equipment applications, traffic studies and operating cost analyses. E-2144.

ELECTRICAL ENGINEER: A. B. degree Princeton; G. E. test course; ten years in steam railroad electrification; Six years originating and developing electric apparatus with two manufacturing concerns, including considerable number of highly successful devices. Location in vicinity of New York preferred. Salary $6600 to $7500. E-2145.

ELECTRICAL ENGINEER: university graduate, age 38, married; fourteen years' experience—drafting, appraising, estimating, designing, layout and installation of large railway distribution system, eight years in responsible charge desires to locate in the west; salary, $5,000. E-2146.

ELECTRICAL GRADUATE: Cooper Union 1918, B.S. degree, Assoc. A. I. E. E., wishes position in New York City in engineering department of progressive concern. Training, experience, and references of the best. American citizen by birth. Salary $50. E-2147.

ENGINEER: as factory or sales executive, technical education, broad experience, initiative, and ability to get results. Seven years with General Electric, designing and sales. At present Sales Manager, heavy machinery for New York and New England. Age 31, salary required $6000. E-2148.

EXECUTIVE: with civil and electrical engineering experience in railroad location construction, Hydro-electric and industrial design, construction and operation. A good organizer with a large following, 38 years old. E-2149.

FACTORY EXECUTIVE: Graduate electrical engineer large experience in mechanical and electrical engineering and factory management. Manager of plants employing 200 to 400. Familiar with modern machine shop practise and methods and equipment for maximum quantity production. Salary $5,000. Available 30 days. Location Northern Ohio. E-2150.

ELECTRICAL SUPERINTENDENT: Age 33, five years practical experience covering shop repair, wiring, testing and trouble shooting, 10 years in charge of installation, maintenance operation, layouts and technical work in connection with the above on cranes, power, lighting and controlling equipment in the iron and steel industry. Fully qualified by experience and training to take charge of both the electrical and mechanical equipment. Address L. F, 34 Brown Ave., Akron, Ohio. E-2151.

INDUSTRIAL ELECTRICAL ENGINEER: Available April 20th. Technical graduate, 10 years experience, generating and substations and distribution systems; designs specifications, schedules, construction, large and small systems. Considerable study given factory power problems and operating features. West or Middle West location preferred. E-2152.

ASSISTANT PLANT OR WORKS ENGINEER: Capable, energetic electrical-mechanical engineer invites correspondence with progressive manufacturing concern desiring the services of an assistant plant or works engineer. Four years experience including G. E. Test, industrial application of power, light, and gas; and the application of A. C. and D. C. power to coal mining. Single, technical graduate, Assoc. A. I. E. E. Salary $2800. E-2153.

ASSISTANT CHIEF ELECTRICIAN: Technical education 9 years experience testing, construction and maintenance of generating stations, substation, underground systems, oxygen Hydrogen Plant, Repair shop and industrial plants. Present salary $2600 Western States. E-2154.

CHIEF ELECTRICIAN: two years technical training, fifteen years practical experience in mining and industrial plants. Age 39 years; salary eighteen hundred per year. E-2155.

GRADUATE ELECTRICAL ENGINEER: Seven years with large power and industrial companies. Experienced in construction and operation of power plants and in operation of transmission lines and electrical equipment. Now employed but available for service on short notice. Salary $250 to $300. E-2156.

DEVELOPMENT OR RESEARCH ENGINEER: Ten years experience Inspection Electrical Testing and special Investigations. Work requiring knowledge of Advanced Mathematics preferred. Location N. Y. C. or vicinity. E-2157.

ELECTRICAL ENGINEER: A.B. and E.E.; seven years experience with a large manufacturer of telephone apparatus; 8 years head of department of electrical engineering in a state university; has done much work of the Dean; desires teaching or commercial position. Minimum salary $4000. Salary scale too low at present location. E-2158.

ELECTRICAL ENGINEER: age 39, with the General Electric Company in the Testing Department two years, in their turbine power station two years, have been with present employers twelve years superintending operation and construction in twelve thousand kilowatt steam turbine driven power station. Have had experience in burning low grade fuels and handling men. Salary $5000.00. E-2159.

ELECTRICAL ENGINEER: age 31, married, 10 years experience construction and installation, sub-station, transmission, distribution and power equipment; also land survey. Can furnish references as to character and ability. No preference as to location. Minimum salary $3000. E-2160.

ELECTRICAL ENGINEER: Assistant professor of Electrical Engineering will be available from June 1st to Sept. 10th. Thoroughly experienced in electrical testing and inside electrical construction work. E-2161.

ELECTRICAL ENGINEER: at present Assistant Superintendent Lighting and Power Public Service Company in city sixty thousand. Technical Graduate, nine years experience General Electric Company and Central Station as Engineer and Executive. Age twenty-nine years, married. Desires change. E-2162.

ELECTRICAL ENGINEER: College graduate 1913. Four years with large traction company and three years with construction company. Drafting, designing, and checking experience on power station and industrial layouts. Field experience. Quick and accurate at engineering computations. Desires connection with engineering office of recognized standing. New England preferred. E-2163.

ELECTRICAL ENGINEER: Cornell M.E. 1918 desires position with industrial concern, manufacturer of electrical apparatus or electrical contractor. Some testing experience; thoroughly familiar with electrical contracting, layouts of lighting systems and power installations. At present employed with large street railway company. Will go anywhere. E-2164.

ELECTRICAL ENGINEER: Cornell graduate, 1918, age 23, single, Associate, desires position in electric furnace field. Six months general testing experience. Lt. S. C. radio for past 18 months engaged in experimental and development work on electric furnaces together with some construction and operation. Salary depending on location. E-2165.

ELECTRICAL ENGINEER: experienced in handling men, general large plant engineering, designing plant installations of motors, generators, substations, over head and underground transmission systems, repairs and maintenance, also

operation of same. Experienced in purchasing and office management, drafting room work desires position as plant engineer or engineer with a firm of consulting engineers. Married, 33 years. Technical training. Salary $7000.00. E-2166.

ELECTRICAL ENGINEER: technical graduate; age 31, ten years experience in design, construction and supervision of maintenance and operation of power plants for industrial plants and public service corporations; Proficient in making estimates, analysis and reports; desires position as electrical engineer for industrial plant or manager for light and power company. E-2167.

ELECTRICAL ENGINEER: technical graduate. Ten years experience in charge of electric construction and operation including power plant and substation work, switchboard, under-transformers and synchronous motors. Best of references. Location, Pacific Coast. Minimum salary $3600. E-2168.

ELECTRICAL ENGINEER: technical graduate seven years experience along construction, maintenance and distribution of power for public utility and construction engineers. E-2169.

ELECTRICAL ENGINEERS: with wide experience in Central Station field and in Industrial power production and application; skilled in preparation of plans, specifications, selection of equipment, organization and control of operating forces; have handled all classes of equipment from water supply to power application. Now open for engagement. E-2170.

ELECTRICAL ENGINEERING INSTRUCTOR: in a leading eastern university,—with past graduate training in Physics, varied engineering and research experience, will be available July 1st for summer or permanent work. Desire engineering or industrial research. Prefer western location for permanent work. Married, age 28. E-2171.

ELECTRICAL AND MECHANICAL ENGINEER: Cornell graduate 1904—Employed as assistant consulting engineer. Experience in all mechanical and electrical features of power and industrial plant design, operation, and maintenance. Minimum salary $5000. Will consider association with Civil and Chemical Engineer for consulting practise in complete design of manufacturing plants and processes. E-2172.

GRADUATE ELECTRICAL ENGINEER: Age 27, married. At present am Sales Engineer for Electric Control Manufacturer. Before leaving Home Office was Asst. Chief Engineer. Desires position with Electric Crane Manufacturer. Salary $225. a month. Location Middle-West. E-2173.

GRADUATE ELECTRICAL ENGINEER: at present employed by large electrical manufacturing company, 1½ years teaching in large university; 2 years mining and general engineering work; 1½ years G. E. Test and engineering department. Thoroughly familiar with mining, power plant and substation work. Available on short notice. E-2174.

GRADUATE ELECTRICAL ENGINEER: possessing unusual qualifications. Four years business, office and sales experience. Six years engineering experience in responsible positions with several large public utility corporations. Especially fitted to handle an executive position of business nature requiring engineering experience and technical knowledge. Now holds an executive engineering position. E-2175.

HYDRAULIC AND ELECTRICAL ENGINEER: University graduate in 1913, seeks a change in position. At present teaching in an Eastern University of first rank, in responsible charge of hydraulic work. Small consulting practise. Work desired is on hydraulic power developments, investigation and design, where executive ability is necessary. Minimum salary $3600. E-2176.

PRACTICAL ELECTRICAL MAN: on D. C. Shop Practise, age 39 yrs., single, about 18 yrs., practical shop experience, graduate of New York Electrical School, at present Chief Electrician in Steel Mill. Service available on two weeks notice. State particulars of position in first answer. E-2177.

PROFESSOR: in charge of Electrical Engineering Department in eastern University desires to make a change this year. Eighteen years teaching and practical engineering experience. Desires either professorship or practical work. Present salary too low. E-2178.

SALES ENGINEER: With Executive experience desires opening as Sales Manager or an Agency with a Company of good standing. Graduate E.E. experienced in test, design, operation and sales of electrical machinery as well as manufacture and operation of storage batteries. Good appearance and forceful personality. Acquaintances in New York and vicinity. E-2179.

TECHNICAL GRADUATE: age 23, five years experience, shop, test engineering, service, sales engineering with large electrical machinery manufacturer desires position, vicinity New York City (not selling) with good future. Minimum salary $2300.00. E-2180.

TECHNICAL GRADUATE: University of Kansas, age 27, energetic, ambitious, four years Philippines and Orient, understanding labor conditions, two years trade school principal, one year superintendent maintenance electric railway, two years captain Coast Artillery, desires position with future. Entrance salary accepted dependent on future possibilities. E-2181.

TECHNICAL GRADUATE: Age 34, married, with eighteen years practical experience, on power and substation operation and maintenance on three large systems. Desires responsible position with utility or industrial company. At present in charge of lighting railway and power substations. Can furnish best of references. Have good reasons for change. E-2182.

TECHNICAL GRADUATE: Three years practical and eight years teaching experience along electrical and mechanical lines. Desires position as supervisor or teacher of electrical subjects. Will consider a commercial position. Age 35, married. E-2183.

TELEPHONE ENGINEER: Graduate Cornell University. Twelve years experience in preparing plans and estimates for inside and outside plant, and in valuation of Telephone and Telegraph Plants. Now engaged in valuation of property for rate case. Minimum salary $3600. E-2184.

YOUNG MAN: Age 28; single; associate; some technical training and five years experience on the operation and maintenance of electrical machinery. Recently from the Naval Service in which held an executive position with an excellent record. Desires position preferably maintenance. Minimum salary $1800. Location New York. E-2185.

TECHNICAL EXECUTIVE OR TECHNICAL ASSISTANT TO EXECUTIVE: Twelve years Public Utility operation, construction and management. Four years executive in charge of power plant and industrial design and construction. Can organize and handle others. Plenty of tact and analytical ability. Available June 1st. E-2186.

DESIGNING ENGINEER: Mechanical, electrical, steel and concrete design of Power Plants and industrial buildings. Efficiency problems and commercial analysis; 10 years experience; whole or part time; located in N. Y. City. E-2187.

GRADUATE ELECTRICAL ENGINEER: middle western university, 1918; age 31; one year post graduate course; one year engineer officer, U. S. Navy; associate, A. I. E. E. Desires position with power or manufacturing company. Available in June. E-2188.

ELECTRICAL ENGINEER: Post-graduate of engineering school. 33 years old, married. Speaks French. Technical experience in electric machinery testing and installation and in storage battery work. Now Assistant Professor of Electrical Engineering in state university. Wishes to engage in commercial work. $300 per month, minimum. E-2189.

TECHNICAL ELECTRICAL MAN: age 28, married, has had 5 years of varied electrical teaching experience. Desires to quit teaching and locate in the southwest. References on request. E-2190.

ELECTRICAL ENGINEER: technical graduate, age 43. Three years in Westinghouse works and testing departments. Eighteen years commercial and technical experience involving negotiations with public utilities and designing of transmission lines, substations and power plants. Salary $6000. Available on reasonable notice. E-2191.

FOREMAN & CHIEF ELECTRICIAN with broad practical engineering experience in industrial and power plants in charge of construction, installation and maintenance. Can maintain essential efficiency in organization. Western states preferred. Fourteen years in business. 31 years of age. Married. Minimum salary to start $2700. E-2192.

STEAM & ELECTRICAL ENGINEER; Assistant to Superintendent or chief engineer in charge of power plants, industrial works or central station. Competent to take charge of operation, efficiency and maintenance of boilers, pumps, turbines, and electrical equipment. Position with good prospects of advancement desired. Salary $2000. E-2193.

MAINTENANCE ENGINEER, age 37, with 20 years, both technical and practical experience in the construction, operation, upkeep and repair of electrical and mechanical equipment of industrial plants, buildings, and railways, including power generation. Married; Associated A. I. E. E. Location immaterial. Available immediately. Salary to commensurate with responsibilities and location. E-2194.

GRADUATE ELECTRICAL ENGINEER, age 32; experienced in installation and maintenance of switchboards and electrical equipment both A. C. & D. C. in steel mills and factories. One years testing experience on A. C. & D. C. motors; three years mechanical design. Minimum salary $4000. Reasonable notice. E-2195.

GRADUATE ELECTRICAL ENGINEER, age 26; single; with two

years experience in telephone engineering, 6 months industrial plant maintenance, and 5 months in the design and layout of power plants and substations, desires change. Location anywhere; East or Middle West preferred. Available on short notice. E-2196.

ELECTRICAL ENGINEER with special training in Mathematics desires position, high tension power work preferred. Graduate A. B. and also E. E. at M. I. T. Fifteen months experience on large power system. Single. Will locate anywhere. Salary about $200. E-2197.

TECHNICAL GRADUATE, 35 years of age, married, executive ability, 10 years experience with operation of electrical and mechanical machinery and equipment, desires a change to a small growing manufacturing concern where the chances of expansion are greater. E-2198.

OBITUARY

JOSEPH T. TOMLINSON, late assistant chief electrician with Spang, Chalfant & Co., Etna, Pa., died March 11, 1920. Mr. Tomlinson was born April 19, 1887, and had been with Spang, Chalfant & Co. since 1905, becoming chief electrician in 1913. He joined the Institute as Associate in 1917.

KATHERINE AUGUSTA, wife of RALPH W. POPE, Honorary Secretary of the Institute, died at her home, 570 Cherry Street Elizabeth, N. J., on March 18 from the effects of cerebral hemorrhage, after an illness of one month. Her remains were taken to Great Barrington, Mass., March 22 for interment in Mahaiwe Cemetery. Mrs. Pope was personally known to many of the Institute members through her presence at several conventions.

JOHN A. BRASHEAR, past president of the American Society of Mechanical Engineers, and chairman of the John A. Brashear Co., Pittsburgh, died April 8, 1920, at his home in Pittsburgh. Born in Brownsville, Pa., in 1840, Mr. Brashear received his education in the public schools there. He early took up a trade as machinist, but following his hobby, astronomy, to which he had devoted much of his spare time, he turned his attention to the construction of astronomical and physical instruments in 1870, and since 1880 was actively engaged in their manufacture. He received honors from many of the leading engineering institutions for his scientific work, and several university degrees. Among P ttsburghers he was widely known as "Uncle John." At the Midwinter Convention of the A. I. E. E. in 1919 he delivered an address before the Institute on "An Evening with the New Astronomy."

JOHN D. IHLDER died on April 3, 1920. Mr. Ihlder was born in Germany in 1848, and had his early school training there, but on coming to America received his college education at Cornell University, from which he was graduated in Electrical Engineering in 1887. Practically all of his work since then has been connected with the Otis Elevator Company, for which he was chief electrical engineer for a number of years, later becoming a member of the Board of Consulting Engineers. The greater part of the electric elevators of the company were built under his patents. Mr. Ihlder was first elected to the Institute as Associate in 1888, becoming a Member in 1903 and a Fellow in 1912. He left New York in 1919 for Cincinnati, Ohio.

THEODORE N. VAIL, a Charter Member of the Institute, and Chairman of the Board of Directors of the American Telephone and Telegraph Company, died at Johns Hopkins Hospital on April 16, 1920. Mr. Vail was born in Carroll County, Ohio, July 16, 1845, his parents soon returning to Morristown, N. J., where he was educated. In later years he received the degree of LL. D. from Dartmouth, Middlebury, Princeton, and Harvard, and the degree of D. Sc. from the University of Vermont. He realy became interested in telegraphy, and abandoned the study of medicine to take up a career as telegraph operator. In 1868 he received an appointment in the railway mail service, and his suggestions for its improvement led to his transfer to Washington in 1875, as general superintendent of the service. Here he met Alexander Graham Bell, and had such faith in his invention of the Telephone that he resigned his position to become head of the first American Bell Telephone Company. When the American Telephone and Telegraph Company was organized in 1885 he became its President, devoting his energies to the extended use of the telephone, and to its development, seizing upon every invention that tended to improve it. From 1887 to 1893 Mr. Vail traveled for his health, and in 1893 retired to his farm in Vermont, but several years later went to Argentina, where he introduced the American system of electric street railways in Buenos Ayres and installed a telephone system in the principal cities of the country, returning to the U. S. in 1904. In 1907 he returned to active work, becoming again the head of the American Telephone and Telegraph Company, with which he remained first as President and later as Chairman of the Board of Directors until his death. During the period of war when the telegraph and telephone properties of the country were taken over by the Government, Mr. Vail was appointed general manager of all telegraph and telephone lines. He always declined to enter public life; although his firm belief was that close cooperation between education, science, and industry were for the best development of the country as a nation. He was a member of many clubs and scientific societies.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Harvey G. Brooke, 6543 Regent, Philadelphia, Pa.
2.—Arthur J. Hall, 634 East End Avenue, Pittsburgh, Pa.
3.—J. C. Lawler, 1817 Glenarm Street, Denver, Colo.
4.—Lincoln Nissley, 1213 Pioneer Bldg., St. Paul, Minn.
5.—Harry E. Stone, 313 Trenton Avenue, Wilkinsburg, Pa.
6.—Lieut. W. J. Strieby, 34 Simpson Road, Ardmore, Pa.
7.—Charles P. Wood, Metuchen, N. J.

INSTITUTE YEAR BOOK

The A. I. E. E. 1920 Year Book is available to members, without charge, upon application to the Secretary, 33 West Thirty-ninth Street, New York.

The book contains an alphabetical and geographical catalogue of the membership revised to January 1, 1920; also the constitution, by-laws, lists of officers and committees, and considerable additional information relating to the activities of the Institute.

SUPER-POWER SYSTEM

At a session of the Institute held during the Midwinter Convention, in February 1920, Mr. William S. Murray presented a paper, published in the March JOURNAL, "Economical Supply of Electric Power;" and during the discussion on this paper a motion was offered and adopted, recommending to the Board of Directors of the Institute that a committee be appointed to carry on the movement as outlined by Mr. Murray.

This recommendation was approved at the meeting of the Board of Directors of the Institute held in Pittsburgh, March 12; and President Townley was authorized to appoint such a committee. In accordance with this action of the Board, President Townley has appointed a Special Committee on Super-Power System, consisting of Messrs. W. S. Murray (Chairman), H. V. Bozell, H. W. Buck, George Gibbs, J. W. Lieb, Malcolm MacLaren, William McClellan, C. S. Ruffner, D. B. Rushmore, Charles F. Scott, Percy Thomas.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (MARCH 1-31 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

AMERICAN CIVIL ENGINEERS' HANDBOOK.

Editor-in-Chief, Mansfield Merriman. Fourth edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 1955 pp., tables, 7 x 4 in., flexible cloth, $6.00.

The fourth edition of this well-known reference work follows the plan of the previous editions and is the achievement of a board of eighteen associate editors, under the direction of Prof. Merriman. The volume has been thoroughly revised, a collection of mathematical tables included and new sections added on electric railways, irrigation and drainage. Nearly four hundred pages have been added to the work. Because of the comprehensiveness of the book, it has been entitled a "Handbook" instead of, as formerly, a "Pocket Book."

AMERICAN MACHINISTS' HANDBOOK.

A Reference Book of Machine Shop and Drawing Room Data, Methods and Definitions. By Fred H. Colvin and Frank A. Stanley. Third edition, thoroughly revised and enlarged. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 758 pp., illus., diagrams, tables, 7 x 4 in., flexible cloth, $4.00.

This pocketbook has been prepared to present in convenient form such data as will be of value to practical men in the various branches of machine work. The present edition has been thoroughly revised. Seventy-seven pages have been added and much other new material included by the elimination of less important matter from the previous edition.

DAVISON'S SILK TRADE.

A Directory of the Silk Manufacturers of the United States and Canada including Silk Dyers, Finishers and Printers; Manufacturers' Agents; City offices and Salesrooms of Silk Mills; Dealers in Raw, Thrown, Spun and Artificial Silk; Waste; Cotton, Tinsel and Worsted Yarns. 25th annual edition, 1920. N. Y., Davison Publishing Co., 782 pp., 7 x 5 in., flexible cloth, pocket edition, $3.00.

The scope of this directory is fully shown by the title. The directory of manufacturers appears in three sections, classified alphabetically, geographically and by the kind of goods made. The other sections are arranged geographically or alphabetically, as seems more expedient. The volume is of pocket size and provided with a marginal index.

ARMATURE WINDING AND MOTOR REPAIR.

By Daniel H. Braymer. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 515 pp., illus., tables, 8 x 6 in., cloth, $3.00.

This book does not discuss the subject from the point of view of theory or design, but is a compilation of practical methods used by repair men and armature winders. The methods selected are those which represent the best practise in repair shops of average size and are given in detail.

DESIGN AND CONSTRUCTION OF HEAT ENGINES.

By Wm. E. Ninde. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 704 pp., illus., diagrams, tables, 9 x 6 in., cloth, $6.00.

CONTENTS: The Heat Engine; Thermodynamics; Friction and Lubrication; Power and Thrust; Mechanics; Machine Design.

The object of this book is to supply in one volume the material most essential to the well-equipped, independent designer of heat engines, and to give this material in the form most convenient for use in class room and practical work by a separate treatment of the different phases of the subject. The book is the outgrowth of twenty years experience, and a study of the literature, drawings and practical data. The volume is confined to the steam engine, steam turbine and internal combustion engine.

THE DESIGN OF SCREW PROPELLERS.

With Special Reference to the their Adaption for Aircraft. By Henry C. Watts. Lond. and N. Y., Longmans, Green and Co., 1920. 340 pp., illus., charts, diagrams, plate, tables, 9 x 6 in., cloth, $8.

During the war, the author was in charge of technical work in connection with propellers for aircraft at the Admiralty and Air Ministry of Great Britain, and many of the propellers used were designed by him or under his supervision. This volume records the results of his experience. It is intended as a guide to practical design and gives slight attention to mathematical theory of the behavior of screw propellers. A chapter on the design of windmills is included.

ELECTRIC LIGHTING.

By Olin Jerome Ferguson. First edition, N. Y., McGraw-Hill Book Co., Inc.; Lond., Hill Publishing Co., Ltd., 1920. 243 pp., illus., diagrams, tables, 9 x 6 in., cloth, $2.50.

While a number of excellent books exist which cover certain portions of the field included in the title of this volume, the author believes that there is need for a work giving a well-balanced presentation of fundamentals, with principles and practise explained throughout. This need he has tried to meet with a textbook of moderate size.

ELECTRIC OSCILLATIONS AND ELECTRIC WAVES.

With Application to Radiotelegraphy and Incidental Application to Telephony and Optics. By George W. Pierce. First edition. N. Y., McGraw-Hill Book Co., Inc.; Lond., Hill Publishing Co., Ltd., 1920. 517 pp., diagrams, tables, 9 x 6 in., cloth, $5.00.

This book is designed to present a mathematical treatment of some of the fundamentals of the theory of electric oscillations

and electric waves. In the selection of material, the writer has given first consideration to that which is particularly applicable to radiotelegraphy, yet he hopes that as the electromagnetic theory involved in radiotelegraphy is also fundamental to optics, telephony and power transmission, his work will also be useful to students of these subjects.

FLOW AND MEASUREMENT OF AIR AND GASES.

By Alec B. Eason. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1919. 252 pp., illus., diagrams, tables, 9 x 6 in., cloth, 25 shillings.

The engineering problems investigated in this book arise in connection with pneumatic tubes and compressed air, gas lighting and ventilating systems. The author has investigated, by study of the literature and by experiment, the friction of gases and the coefficient of friction in pipes, the question of suitable meters for gas and air, and the working of pneumatic tubes; and has attempted to coordinate the results of the various tests and formulas, so that the reason for variations may be appreciated. Full references to the sources of information are given.

GRAPHIC PRODUCTION CONTROL.

By C. E. Knoeppel, assisted by Various Members of the Author's Firm and Staff. N. Y., The Engineering Magazine Co., 1920. 477 pp., illus., diagrams, charts, 9 x 6 in., cloth, $6.00.

This treatise on the use of graphic charts in shop control is intended to provide a complete description of the proper methods of making graphic charts and of applying them to industrial problems. The general principles of graphic control, the preliminaries of its installation, the practical operation of the system, etc., are discussed in detail.

HENDRICKS' COMMERICAL REGISTER OF THE UNITED STATES FOR BUYERS AND SELLERS.

28th Annual edition, 1919–20. N. Y., S. E. Hendricks Co., Inc. 2541 pp., 10 x 8 in., cloth, $12.50.

This new edition, like its predecessors, is devoted to the electrical, engineering, hardware, iron, mechanical, mill, mining, architectural, quarrying, chemical, railroad, steel, contracting and kindred trades. The firms included are listed alphabetically and by products. A subject index and an index of trade names are also included.

INTRODUCTION TO GENERAL CHEMISTRY.

By Herbert N. McCoy and Ethel M. Terry. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 648 pp., illus., 9 x 6 in., cloth, $3.00.

This textbook is intended as an introduction to general chemistry for use by college freshmen and is based on the course in the University of Chicago. The aim has been to present a continuous, connected story in teachable form, without unnecessarily extensive descriptive and numerical data.

In this edition misprints have been corrected and a chapter on metallurgy added.

THE IRON HUNTER.

By Chase S. Osborn. N. Y., The Macmillan Co., 1919. 316 pp., plates, portraits, 8 x 5 in., cloth, $2.00.

Ex-Governor Osborn of Michigan has been closely associated with the development of the iron ores of the Northwest and of Canada from the early "eighties" to the present. It has been his hobby to visit all the commercial iron fields of the world. His autobiography is an interesting, unconventional account of his life as a journalist, prospector and statesman, full of information about men and affairs during the early mining days in Wisconsin and Michigan.

MANUAL OF CYANIDATION.

By E. M. Hamilton. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 277 pp., illus., tables, 7 x 5 in., flexible cloth, $3.00.

The aim of this book is to provide in a handy sized volume a compendium of all the ascertainable facts concerned with the cyanide process that may have a practical bearing on testing an ore, planning the flowsheet and operating the plant when erected. Purely theoretical questions have been left in the background.

MENSURATION FOR MARINE AND MECHANICAL ENGINEERS.

(Second and First Class Board of Trade Examinations). By John W. Angles. Lond. & N. Y., Longmans, Green and Co., 1919. 162 pp., illus., diagrams, 7 x 5 in., cloth, $1.75.

This textbook is intended to enable students to pass the examinations of the Board of Trade (Great Britain) for licenses as marine engineers, but will be useful, the author hopes, to engineering students in other lines. A feature is made of fully solved examples, illustrating the practical applications of the theoretical principles involved in the text.

METALLOGRAPHY. Part I. Principles of Metallography.

By Samuel L. Hoyt. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 256 pp., illus., diagrams, tables, 9 x 6 in., cloth, $3.00.

This volume, the first of a series of a series of three based on the author's lectures at the University of Minnesota, deals with general principles and with some of the more important methods used in general investigations in the metallographic laboratory. Future volumes will discuss the metallography of the metals and alloys and the applications of metallography to the metallurgical and engineering industries.

MICROSCOPIC EXAMINATION OF THE ORE MINERALS.

By W. Myron Davy and C. Mason Farnham. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 154 pp., illus., tables, 9 x 6 in., cloth, $2.50.

The authors present a table for determining the identity of ore minerals by means of the reflecting microscope and microchemical tests, for the use of mineralogists, geologists and engineers. In addition to the table, instruction in polishing and examining specimens and in photomicrography is given, as well as a collection of supplementary tests.

MINERAL RESOURCES OF ARMENIA AND ANATOLIA.

By Hagop A. Karajian. First edition. N. Y., Armen Technical Book Co., 1920. 211 pp., illus., maps, 9 x 6 in., cloth, $3.

A summary of our knowledge of the mineral resources and the present state of the mining industry in Armenia and Anatolia, accompanied by a survey of the geology of the region. A number of sketch maps and a bibliography are included.

MOTOR VEHICLE ENGINEERING.

Engines (For Automobiles, Trucks and Tractors). By Ethelbert Favary. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 333 pp., illus., plates, tables, 9 x 6 in., cloth, $3.50.

The author states that many chapters of this edition have been entirely rewritten, that the practical data have been brought up to date and that the work has been generally revised. The book treats of automobile engines and is intended to give a concise, simple statement of the everyday information needed by automotive engineers.

L'OR. Prospection—Gisement—Extraction.

By Georges P. Proust. Paris, Gauthier-Villars et Cie, 1920. 319 pp., illus., 9 x 6 in., paper, 10 francs.

This work by a French mining engineer is a summary account of the mining and metallurgy of gold. After an introductory chapter on mineralogy, the author treats of prospecting and testing, exploitation, preparatory treatment, cyaniding, mining costs and alluvial mining. A chapter of advice on hygiene and diet for residents in tropical lands is included, and also a mineralogical lexicon. The book is evidently intended for engineers engaged in the development of new mines.

THE ORGANIZATION OF INDUSTRIAL SCIENTIFIC RESEARCH.

By C. E. Kenneth Mees. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 175 pp., 8 x 6 in., cloth, $2.00.

CONTENTS: Types of Research Laboratories; Co-operative Laboratories; Position of the Research Laboratory in an industrial Organization; Internal Organization of Industrial Research Laboratories; Staff of a Research Laboratory; Building and Equipment of the Laboratory; Direction of the Work; Design of a Research Laboratory for a Specific Industry.

This volume is a contribution to the current discussion of the relation of scientific research to industry. The author is concerned with a study of the best methods of organizing research work for industrial purposes and of the conditions under which such work should be conducted, and has made an effort to give definite suggestions upon these points. The book is intended for those who plan to undertake research work rather than as an exposition of its theoretical advantages.

Statistics in Business.

Their Analysis, Charting and Use. By Horace Secrist. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 137 pp., illus., diagrams, maps, tables, 8 x 6 in., cloth, $1.75.

This volume has been prepared to serve as a handbook for executives in the application of business statistics to problems which arise. It aims to present briefly and concretely the reasons why statistics should be used in business analysis and to illustrate how and with what effect they may be applied to the solution of business problems. The discussion is of a practical nature. Especial attention is given to the use of charts and graphs. Examples of good and bad usage are given.

Thomas' Register of American Manufacturers and First Hands in All Lines. 11th edition, 1920.

N. Y., Thomas Publishing Co., 1920. 12 x 9 in., cloth, $15.00.

Contents: Finding List and Index; Lists of Manufacturers Classified according to Business; Manufacturers of the U. S. arranged alphabetically; Leading Trade Names, Brands, etc.; Banks, Boards of Trade and other Commercial Organizations, Leading Trade Papers; Manufacturers' Representatives; Export and Import Houses; Steamship Lines and Forwarding Agents, Banks, etc.; Overseas Importers, Merchants, etc.

The eleventh edition of this widely known directory has been revised and enlarged to the size of 4500 pages. It covers manufacturers and dealers in all classes of materials, and contains a classified list of manufacturers with indications of their approximate ratings, an alphabetical list of the more important firm names, and a list of brand or trade names of manufactured articles.

White-Lead—Its Use in Paint.

By Alvah Horton Sabin. First edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 133 pp., tables, 8 x 5 in., cloth, $1.25.

In his small work Dr. Sabin has provided a brief, non-tehnical account of the subject for the instruction and guidance of those whose need and use of white-lead prompts them to seek knowlledge about it of a simple but reliable sort. The various methods of making white-lead are given together with the properties of the usual substitutes, methods of mixing paid for different purposes, etc.

Notes on Magnetism.

For the Use of Students of Electrical Engineering. By C. G. Lamb. Cambridge, England, University Press, 1919. 94 pp., 55 illus., 9 x 5 in., paper. (Gift of G. P. Putnam's Sons).

The author presents an outline of those essential parts of magnetic theory which a student of electrical engineering requires in order to read ordinary technical textbooks with intelligence. The book is based on the course at Cambridge University.

CONTROLLERS FOR ELECTRIC MOTORS

By H. D. James. D. Van Nostrand & Co. 1919.

The use of the electric motor has become so wide-spread and the methods of its application and control so numerous that at present none but a specialist is competent to make a decision from his own experience as to the most suitable motor and most appropriate method of control for the manifold applications. On the other hand these applications are so common that most practising engineers must frequently make recommendations of this character incidental to other engineering work.

The book "Controllers for Electric Motors" is a compilation of descriptions of the many ways in which motors are used in industrial work and of accepted methods of control for each process by a specialist who is recognized in the professional world as an authority on this subject. The list of applications discussed in the book is so long that only the most interesting can be mentioned here. Many of the discussions of the underlying engineering features have been given by the same author in the Transactions of the A. I. E. E.

One of the most interesting and valuable sections is that in which the author attacks the common fallacy of basing the determination of the requisite number of steps of a starting box on considerations of the resistance of the armature circuit alone. By means of a scientific analysis, illustrated by oscillograms the author points out that due to the fact that a measurable period of time is required for the field of a d-c. motor to build up, and since during this period the torque cannot be sufficient to cause a dangerous mechanical shock to the motor or gear, it is good engineering to take advantage of this feature to reduce the number of steps (and cost) of a starting rheostat.

The relative advantages of d-c. and a-c. motors for various applications are discussed very thoroughly and impartially and a good reason is given for every definite recommendation.

The use of auxiliary fly-wheel motor-generator sets, both with d-c. and a-c. motors is explained and the economic justification stated. However the latest type of speed control of large induction motors by means of a polyphase commutator motor is not described.

Many recently developed types of relays and magnetic switches are described and the possibility of developing the protective and automatic features of a control to an unnecessary complexity is clearly brought out with citations of cases where certain apparently highly desirable devices have been abandoned after some trial for the purpose of getting greater simplicity and ease of repair.

The success of the electric motor in supplanting the hydraulic drive for elevators is noticeable by the number of methods in which the motor has been adapted in commercial practise both for passenger and freight service. The saving in space required for the driving machinery is a very important factor in these days of high building costs. It would be almost impossible to construct a hydraulic elevator for a 40-story building whereas the adaptation and control of the electric motor has been worked out with interesting ingenuity.

Electric Drive in Steel Mills is a subject which hardly comes into the activities of the average general engineer because it is so involved as to be a specialty in itself, yet all engineers are interested in knowing the wonderfully clever things that have been accomplished in this line.

The Mining Industry has been one of the last and most difficult fields for the electric motor to enter and capture but it is clearly evident that the electrical engineer interested in this specialty has been very industrious and has produced a large number of ingenious devices which do very important work for the mining engineer. With the continual increase in the price of coal the time will soon arrive, if it has not already, when the mining plant cannot afford to generate its own power but will be forced by economic pressure to buy energy from the large electric power companies which by a peculiarity of nature usually find abundant water power in the vicinity of a mining country. When the mining engineer has to buy his energy in the form of electric current instead of coal he will fully appreciate the advantage of using it in the electric motor and then it may be fairly said that the electric motor has conquered all industrial fields. W. I. S.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Baltimore.—February 20, 1920, Engineers Club. Speaker: Mr. H. G. Barnhart, Chief Engineer, Fuller Engineering Company. Subject: "Pulverized Fuel and Its Uses." The talk was illustrated by lantern slides and was followed by a lively discussion. Attendance 40.

March 19, 1920, Johns Hopkins University. Paper: "High Speed Trans-Oceanic Wireless Reception." Author: Mr. C. H. Hoxie, General Electric Company, Schenectady. The paper gave the steps in the development of a high speed photographic wireless receiver and was illustrated by lantern slides. Attendance 35.

Chicago.—March 4, 1920, Rooms of Western Society of Engineers. Joint meeting with American Society of Mechanical Engineers, Western Railway Club and Western Society of Engineers. Subject: "Some Comments on Present Status of Steam Railroad Electrification." Speaker: Mr. S. T. Dodd, G. E. Co., Schenectady, N. Y. Attendance 250.

March 29, 1920, Western Society of Engineers Hall. Paper: "Transmission of Intelligence." Author: Mr. O. B. Blackwell, A. T. & T. Co., New York. The paper first described in general terms the various means of transmission of intelligence with limitations of each, but was confined chiefly to a general description of the latest development in long distance telephone communication. Attendance 215.

Cleveland.—March 16, 1920, Rooms of Cleveland Engineering Society. Paper: "The Vacuum Tube and Some of its Applications." Author: Mr. J. W. White, G. E. Co., Schenectady, N. Y. The paper was illustrated by lantern slides. Attendance 141.

Denver.—March 27, 1920. After a dinner at the Kenmark Hotel the meeting adjourned to the Denver Gas & Electric Light Company's electrical laboratory, where a very interesting and instructive talk by Mr. H. P. Tewksbury was made on electrical measuring instruments. The talk was illustrated by actual apparatus and demonstrations of some of the tests which are carried out in connection with the meter department. Active discussion followed. Attendance 40.

April 2, 1920, Shirley Hotel, following a dinner in honor of Mr. F. W. Peek, Jr., G. E. Co., Pittsfield, Mass. Mr. Peek spoke on the problems of high tension transmission and pointed out the main factors entering into the development of 210,000 volt transmission lines. Attendance 60.

Detroit-Ann Arbor.—March 12, 1920, Board of Commerce. Round Table Talk. Subject: "The Measurement of Power and the Significance of Power Factor in Single Phase and Three Phase Circuits." The discussion was led by Prof. H. H. Higbie, University of Michigan. Attendance 60.

Erie.—March 10, 1920, Commerce Rooms. Subject: "Vacuum Tubes." Speaker: Mr. W. C. White, G. E. Co., Schenectady, N. Y. Attendance 125.

Fort Wayne.—February 19, 1920, G. E. Club Room. Subject: "Autogenous Welding." Speaker: Mr. Howard Miller, G. E. Co., Fort Wayne. Attendance 40.

Indianapolis-Lafayette.—March 19, 1920, Chamber of Commerce. Subject: "Industrial Efficiency Instruments." Speaker: Mr. D. G. Angus, of the Esterline Co., Indianapolis. Attendance 55.

Ithaca.—February 27, 1920, Franklin Hall, Cornell University. Subject: "Operating Performance of Insulators on a 45,000 Volt System." Speaker: Mr. H. B. Vincent, Management Engineer, Day & Zimmerman, Inc. Attendance 50.

March 5, 1920, Sibley Dome, Cornell University. Joint meeting with the Cornell Branch A. S. M. E. Subject: "The One Best Way" as a solution of the industrial problem. Speaker: Mr. Frank B. Gilbreth. The lecture was illustrated by lantern slides and motion pictures. Attendance 200.

March 19, 1920, Franklin Hall, Cornell University. Subject: "The Manufacture and Application of the Modern Incandescent Lamp." Speaker: Mr. A. L. Powell, Illuminating Engineer, Edison Lamp Works. Attendance 80.

Lynn.—March 3, 1920, G. E. Theatre. Subject: "Latest Developments in Lighting." Speakers: Messrs. G. N. Chamberlain and A. B. Halborson, engineers of the Street Lighting Dept. of the Lynn Works, G. E. Co. The lecture was supplemented by experiments and exhibition of the performance of different types of new apparatus that have been recently developed in the lighting field of the Lynn Works. At the conclusion of the lecture a series of films was shown which were loaned by the War Department showing the service test given to the 60″ searchlight equipment which had been perfected for the Army. Attendance 165.

Milwaukee.—April 8, 1920, Milwaukee Athletic Club. Mr. Tatum, of Cutler-Hammer Mfg. Co., gave an interesting talk on high speed tool steel. Mr. Simon, also of Cutler-Hammer Mfg. Co., gave a brief outline of proposed plan of summer school especially adapted for engineers in professional life who have been out of college long enough to feel the necessity of brushing up on special subjects. Attendance 70.

New York.—March 26, 1920, Engineering Societies Building. Paper: "Gaseous Conduction Light from Low Voltage Circuit." Author: Mr. D. McFarlan Moore. The paper was illustrated by stereopticon slides and demonstrations.

Philadelphia.—April 11, 1920, Engineers' Club. Dinner followed by meeting. Subject: "Traffic Engineering." Speaker: Mr. Frank B. Evans, Jr., Bell Telephone Co. of Pennsylvania. Attendance 75.

Pittsburgh.—February 21, 1920, Chatham Hotel. Joint meeting with Association of Iron & Steel Electrical Engineers. Subject: "Manufacture and Use of Graphic Recording Instruments." Speaker: Prof. J. W. Esterline. Attendance 200.

April 13, 1920, Chamber of Commerce. Subject: "A Modern Coal Mine Hoist Installation." Speaker: Mr. Graham Bright, W. E. & M. Co. Attendance 52.

Pittsfield.—March 18, 1920, Park Club. Subject: "Do we live on the Inside or Outside of the Earth." Speaker: Mr. C. A. S. Howlett, Devine Cushion Wheel Co., Utica, N. Y. Attendance 125.

April 1, 1920, Park Club. Subject: "Power and Transmission." Speaker: Mr. H. H. Dewey, G. E. Co., Schenectady, N. Y. Attendance 100.

Portland.—March 9, 1920, University Club. Business meeting followed by presentation of paper on: "Industrial Development of the Portland District" by Mr. W. H. Crawford, of the Portland Chamber of Commerce. Attendance 19.

Providence.—April 13, 1920, Providence Engineering Society. Organization meeting; election of officers as follows: Chairman, Ralph W. Eaton; Vice-Chairman, Nicholas Stahl; Secretary and Treasurer, Frederick N. Tompkins. Attendance 12.

St. Louis.—February 25, 1920, Engineers' Club. Business meeting, followed by presentation of a paper on: "Design, Manufacture and Use of Graphic Instruments" by Mr. D. J. Angus, of the Esterline Company, of Indianapolis. Attendance 40.

March 31, 1920, Engineers' Club. Papers: "An Automobile Ignition System," by Mr. F. B. Avery, Wagner Electric Manufacturing Company; "Insulating Materials" by Mr. H. A. Richards, Century Electric Company; "Overhead Line Pro-

tection" by Mr. C. H. Kraft, Union Electric Light and Power Company. Attendance 104.

San Francisco.—March 25, 1920. Subject: "War-Time Research." Speaker: Professor Harris J. Ryan. Attendance 90.

Schenectady.—April 2, 1920, Edison Club Hall. Paper: "The Alternating Current Commutator Motor." Author: Mr. B. G. Lamme, Chief Engineer, Westinghouse Elec. & Mfg. Co. Mr. Lamme briefly outlined the history of the development of several of the types of a-c. commutator motor. By using the same method of analysis he compared several types of commutator motors and pointed out the different characteristics of each. By means of blackboard sketches Mr. Lamme reproduced a number of the illustrations given in his paper which was published in the March issue of the JOURNAL By comparison of d-c. motors and a-c. commutator motors it was shown that the problems of commutation were practically the same for both types providing all characteristics are taken into account. Attendance 290.

Seattle.—March 16, 1920, Arctic Club Assembly. Business meeting, followed by presentation of paper on: "Some Elements for Consideration in Valuations" by Mr. Thomas E. Phipps. Attendance 45.

Toronto.—March 19, 1920, Engineers' Club. Business meeting. In place of a formal paper, the meeting took the form of a competitive presentation of original inventions. A committee of judges was appointed, after which the Chairman called on Mr. P. A. Borden to preside, as he had been responsible for all arrangements. Some interesting and very original ideas were presented by several of the members of the Section, and a very active discussion was taken part in by Messrs. Brandon, Wright, Price D'Alton, Hull, Anderson, Cooper, Stephens, Hookway, Mitchell, Bucke, Winter Joyner, Stevenson, Clarke, Lines and Borden. Attendance 92.

March 5, 1920, Engineers' Club. Paper: "General Problems of Operation." Author: Mr. H. C. Don Carlos. Quite a number of very interesting slides were shown and the paper covered a very wide field, including ice troubles at the power house, voltage regulation, insulator failures and changing insulators on live lines, weather conditions as affecting transmission lines and outdoor switching. Attendance 128.

Washington.—March 19, 1920, Willard Hotel. Joint meeting with the Illuminating Engineering Society. Subjects: "R. L. M. Standards of Industrial Lighting" by Mr. W. Harrison National Lamp Works; "Residence Lighting" by Mr. M. Luckiesh, NELA Research Laboratories. Both lectures were illustrated by lantern slides. Attendance 300.

April 13, 1920, Cosmos Club. Business meeting, followed by an illustrated address on the "Design of a Superpower Station" by Mr. Harold Goodwin, Jr. Attendance 105.

Worcester.—April 12, 1920, Worcester Polytechnic Institute. First meeting of Section. Business meeting and election of officers as follows: Chairman, C. R. Oliver; Vice-Chairman, G. M. Hardy; Secretary-Treasurer, Dean J. Locke. Subject: "The Effect of Power Factor and Load Factor upon Central Station Rates" by Prof. C. F. Harding, Purdue Univ. Attendance 102.

PAST BRANCH MEETINGS

University of Arkansas.—February 10, 1920, Physics Bldg. Subjects: "The Electrical Industry" by S. E. Hollabaugh, with slides furnished by G. E. Co.; "The Use of High Pressure Boilers" by R. W. Jacobs. Attendance 21.

February 24, 1920, Engineering Building. Subjects: "Development of the Rotary Converter" by Lance Anderson; "Review of Technical Press" by C. A. Smith; "Labor Problems" by J. B. Rodgerson; "The Uniflow Engine" by Bohart Cowan. Attendance 12.

March 12, 1920, Physics Building. Subject: "The Manufacture and Use of Lightning Arresters and Transformers." Speaker: Mr. H. F. McRell, G. E. Co. Attendance 37.

Armour Institute of Technology.—March 4, 1920, Armour Lecture Room. Business meeting. Attendance 32.

March 18, 1920, Armour Lecture Room. Subjects: 'The Application of Electricity to Mechanical Measurements" by J. W. Naiman, '21; Public Utilities and Their Relation to the Engineering Graduate" by Mr. R. C. Newbury, Denver Gas & Electric Light Co. Attendance 80.

Brooklyn Polytechnic Institute.—March 19, 1920. Subject: "General Testing." Speaker: Mr. F. W. Magalhaes. A demonstration of wireless telephony was given by members of the Radio Branch. Refreshments were served. Attendance 33.

Bucknell University.—April 12, 1920, Bucknell Chapel. Films entitled "The King of the Rails" and "The Electrical Giant" were shown. Attendance 42.

University of California.—February 25, 1920, Mechanics Bldg., Paper: "Inductive Interference in Telephone Circuits." Author: Mr. D. I. Cone, of the Pacific Telephone & Telegraph Co. Attendance 45.

March 10, 1920, Mining Building. Film entitled "Queen of the Waves" was shown. A description of the interesting features of the U. S. S. New Mexico was given by Mr. W. J. Davis, Pacific Coast Engineer of the G. E. Co.

March 24, 1920, Mechanics Building. Paper: "Multiplex Telephony and Telegraphy" by Mr. V. D. Cousins, of the Pacific Telephone & Telegraph Company. Attendance 41.

April 7, 1920, Mechanics Building. Business meeting with election of officers for the coming year as follows: Chairman, E. M. Brown; Vice-Chairman, C. E. Baston; Secretary, R. B. Stewart; Treasurer, R. D. Miller. Attendance 22.

University of Cincinnati.—February 17, 1920, Assembly Hall, Engg. Bldg. Business meeting. Attendance 46.

March 2, 1920, Engg. Bldg. Subject: "Ball Bearings for Electrical Machinery." Speaker: Mr. J. Davis, of the SKF Ball Bearing Co. Attendance 68.

March 16, 1920, Engg. Bldg. Subject: "Fire Alarm System." Speaker: Mr. C. S. Jones, Supt. of Cincinnati Fire Alarm Telegraph Co. Attendance 76.

March 23, 1920, Engg. Bldg. Mr. C. S. Jones repeated the paper given at meeting on March 16, 1920. Attendance 52.

April 7, 1920, Engg. Bldg. Subject: "Refilling burnt out Mazda Lamps, as carried out by a Plant at Franklin, Ohio." Speaker: Mr. F. J. Kepler, '20. Attendance 61.

April 13, 1920, Engg. Bldg. Subject: "Commercial Trouble Shooting." Speaker: Mr. S. F. High, '20. Attendance 69.

University of Colorado.—April 1, 1920, Hale Science Bldg. Mr. F. W. Peek, G. E. Co., gave a talk on the problems of power transmissions, especially at the super-voltages, which was greatly enjoyed by all. Attendance 118.

Georgia School of Technology.—March 18, 1920, Physics Lecture Hall. Subject: "Sales Engineering." Speaker Mr. W. R. Collier, Sales Manager of the Georgia Railway and Power Company. Attendance 42.

March 25, 1920, Y. M. G. A. Auditorium. Illustrated lecture on the "Manufacture of Steel Rails" by Professor R. S. King; and "The Birmingham Inspection Trip" by Professor C. P. Eldred. Attendance 70.

April 8, 1920, Y. M. C. A. Auditorium. Subject: "Electric Ship Propulsion." Speaker: Mr. H. E. Bussey, of the G. E. Co. A film entitled "Queen of the Waves" was then shown, bearing on the subject of the talk. Attendance 75.

State University of Iowa.—February 10, 1920. Physics Bldg. Subject: "The Cedar Rapids Automatic Hydro-Electric Plant" by Geo. Holmes. Attendance 17.

February 22, 1920, Physics Building. Subject: "Electric Drive on the Battleship New Mexico" by K. B. Lambert. Attendance 12.

March 9, 1920, Physics Bldg. Subject: "Electric Motor Controllers" by E. M. Boton, of the W. E. & M. Co.

March 23, 1920, Physics Bldg. Subject: "Electric Fires" by J. B. Demster. Attendance 15.

April 6, 1920, Physics Bldg. Subjects: "The Safety Features of the Birney Safety Car" by L. Rohret; "The Operation of the Magnetic Clutch" by M. L. Banks.

University of Kentucky.—March 22, 1920, Mechanical Hall. Subjects: "Essential Statistics for General Comparison of Steam Power Plant Performance" (Feb. JOURNAL) by N. T. Puckett; "Day Light Saving" (Feb. JOURNAL) by H. T. Weinshank; "The Last Stand of the Reciprocating Engine" (March JOURNAL) by W. M. Wallace; "The Engineer, Employer and Employee" (March JOURNAL) by U. V. Garred; "Constant Potential Series Lighting" (March JOURNAL) by J. D. Wood. Attendance 19.

Kansas State Agricultural College.—March 4, 1920. Subject: "One Phase of the Labor Situation." Speaker: George Clammer. Attendance 78.

March 11, 1920. Election of officers as follows: President, C. F. Joss; Vice-President, E. G. Abbott; Secretary, R. S. Breese; Treasurer, M. Stigers. Subject: "Transmission Line Construction." Speaker: Kenneth Houser. Attendance 65.

March 18, 1920. Subjects: "Advertising the Engineering College over the State" by Martin Soule; "What Makes a Successful Man" by Dr. J. R. Macarthur. Attendance 73.

April 1, 1920. Subjects: "Progress of the Electrical Field" by Mr. Posey; "Use of Our Mistakes" by Mr. Fisher; "Why Kansas State Agricultural College should change its name to Kansas State College" by G. R. Rush; "Electric Propelling Machinery on the U. S. S. *Tennessee*" by Lloyd Zimmerman; extemporaneous talk, C. E. Reid. Attendance 58.

Lehigh University.—March 12, 1920, Physics Bldg. Subject: "Central Station Development" by Mr. N. E. Funk, Philadelphia Electric Company. Social hour and refreshments. Attendance 56.

April 15, 1920, Physics Bldg. Subject: "Superpower Station for the Union Francaise" by Harold D. Goodwin, Jr., G. E. Co. Attendance 90.

University of Maine.—March 4, 1920, Lord Hall. Business Meeting, followed by presentation of a paper on "Electric Propulsion of Ships" by Lawrence Merrow. Professor Barrow spoke on the present situation in New England regarding electric power supplies. Attendance 19.

Massachusetts Institute of Technology.—March 23, 1920." Subject: "General Problems of Telephone Engineering. Speaker: Mr. G. K. Manson, N. E. T. & T. Co. Attendance 50.

Michigan Agricultural College.—March 11, 1920, R. E. Olds' Hall. Election of officers as follows: Chairman, M. B. Rann; Secretary, J. F. Van Ark. Attendance 18.

University of Michigan.—March 25, 1920, Engg. Bldg. Business meeting, followed by a talk by Mr. H. S. Osborne, of the A. T. & T. Co. on "Electrical Transmission of Thought and Power. Attendance 65.

School of Engineering of Milwaukee.—March 19, 1920. Subject: "Heat Treatment of Steel." Speaker: "Mr. G. W. Esau, Chief Engineer of the Modern Heat Treating Steel Company. Attendance 90.

University of North Carolina.—February 2, 1920. Talks as follows: "Storage Batteries" by M. E. Lake; "Operation of Storage Batteries" by G. T. Finger; "High Tension Insulators" by C. D. Blair; "Electricity on the Farm" by C. G. Lancaster. Attendance 40.

March 1, 1920.—Business meeting and election of officers. Talks as follows: "Commutation of D. C. machines" by P. C. Smith; "Air Gaps of D. C. Machines" by T. E. Hinson; "Testing of D. C. Machines" by A. B. Right; "Rating of D. C. Machines" by L. V. Milton. Attendance 52.

March 26, 1920. Illustrated lecture by C. S. Coler, of W. E. & M. Co. Attendance 38.

Ohio Northern University.—March 18, 1920, Dukes Memorial. Subjects: "The Development of Hydro-Electric Plants" by Mr. J. W. Ulrey; "Machine Gun Ammunition Testing" by R. L. Quigley; "Signal Corps Work" by M. E. Elder. Attendance 19.

University of Oklahoma.—March 25, 1920. Subject: "Modern Developments in Radio Telephony" Speaker: Prof. Wm. A. Schriever. Attendance 34.

Oregon Agricultural College.—February 26, 1920. Business meeting. The following films were shown: "The Conviction of Si Smith;" "The Electrical Giant" and "The Potters Wheel." Attendance 53.

University of Pittsburgh.—January 27, 1920. Subject: "The History of the Transmission of Electricity." Speaker: Mr. P. M. Lincoln. Attendance 15.

February 17, 1920. Election of officers as follows: Chairman, W. F. Young; Vice-Chairman, C. R. McGann; Secretary, J. C. Wolfe. Attendance 14.

March 2, 1920. Subject: "The History of Electricity." Speaker: Prof. H. E. Dyche. Attendance 21.

March 9, 1920. Subject: "Automatic Substation." Speaker: Mr. James C. Wolfe. Attendance 21.

March 16, 1920. Illustrated Paper "Electrification of the C. M. & St. P. Railroad." Speaker: Mr. G. B. Anderson. Attendance 21.

March 23, 1920. Paper: "Eastern Power Development." Speaker: Mr. W. F. Young. Attendance 17.

March 30, 1920. Subject: "The Electrification of the Norfolk and Western Railroad." Speaker: Mr. W. T. Askin. Attendance 19.

April 6, 1920. Subject: "Review of the Electrical Development for the Year 1919." Speaker: Mr. J. F. Keller. Attendance 28.

Purdue University.—March 8, 1920. Business meeting, followed by presentation of the following papers: "The Westinghouse Company and Its Work" by Mr. Kottman; "Work on the Duquesne Power Plant" by Mr. Skinner; "Electrolysis" by Mr. C. F. Mitchell '20, and G. C. Schleter '20. Attendance 100.

March 15, 1920. Business meeting, and election of officers as follows: Chairman, W. A. Clark; Vice-Chairman, E. R. Moore; Secretary, G. R. Dittwe; Treasurer, J. H. Dagenhart. Paper: "Telephone Transmission" by Mr. H. S. Osborne. Attendance 105.

April 6, 1920. Paper: "The Cash Register." Speaker: Mr. W. E. Carr. Attendance 45.

Stanford University.—March 10, 1920. Mech. Engg. Bldg. Illustrated lecture by Professor Harris J. Ryan on the Los Angeles Aqueduct. Attendance 38.

March 15, 1920. Election of officers as follows: Chairman, Raymond Lewelling; Secretary-Treasurer, Harry P. Wickersham. Professor Harris J. Ryan spoke on "The Hisotry of the Development of the A. I. E. E. from 1900 to 1920. Attendance 14.

University of Virginia.—April 1, 1920, Mechanical Laboratory. The following addresses were delivered: "Signal Characteristics and Operation" by Mr. Wagner; short address by Dr. Carl Hering approving and encouraging the establishment of a course in railway signaling at the university of Virginia; short address by Mr. Livers, President of C. &. A. Railway, on practical experiences in electrical work, both constructing and operating. Attendance 22.

Washington State College.—March 12, 1920. Film entitled "The Spirit of Progress" was shown. Attendance 42.

University of Wisconsin.—January 22, 1920. Engg. Bldg. Business meeting, followed by a talk by Mr. Miller, of the Wisconsin Rate Commission, on "Procedure in Establishing Rates for Public Utilities in Wisconsin." Attendance 33.

February 25, 1920, Engg. Bldg. Three short talks by Students were given as follows: "Graduate Test Course at Westinghouse Elec. & Mfg. Co., by D. R. Lamont; "Opportunitise in Railway Signalling" by Harold P. S. Day; "Test Course for Graduates at G. E. Co." by R. R. Knoerr. Attendance 43.

March 10, 1920, Engg. Bldg. Business meeting followed by a talk by Mr. Garber, of the Western Electric Co. on "Manufacturing Conditions at the Hawthorne Works. Attendance 65.

March 19, 1920. Subject: General Features of Telephone Transmission with Particular reference to its relation to Power Transmission. Speaker: Mr. Harold S. Osborne, of the A. T. & T. Co. Attendance 59.

Yale University.—February 18, 1920, Dunham Lab. of E. E. Business meeting. Attendance 14.

March 19, 1920. Dunham Lab. of E. E. Illustrated lecture by Mr. Charles Rufus Harte on "Power Transmission Lines." Attendance 60.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED APRIL 9, 1920

Adams, Harvey P., Manager, A. & B. Company, McAllen, Texas.

Adams, Howard H., Cadet Engineer, United Improvement Co., 1401 Arch St., Philadelphia, Pa.

Adams, Myron W., Engineer, Operating Dept., New England Power Co., Millbury, Mass.

Aitchison, Willard L., Inspector, Western Electric Co. Inc., 203 Broadway, New York; res., 92 Monroe St., Brooklyn, N. Y.

Anderson, E. W., Asst. Inspector, Public Service Co. of Northern Illinois, Evanston; res., 1254 N. La Salle St., Chicago, Ill.

Anderson, Wm., Prof. of Physics & Elec. Engg., Rhode Island State College, Kingston, R. I.

Anderson, William F., Junior Engineer, Toledo Railways & Light Co.; res., 304 18th St., Toledo, Ohio.

Andrews, Fred A., Station Supt., New England Power Co., Hoosac Tunnel, Mass.

Antoniono, Caesar, Foreman of Electrical Construction, Chicago, North Shore & Milwaukee Railroad, 72 W. Adams St., Chicago, Ill.

Arledge, George H., Asst. Engineer (Steam), War Department, Supply Div.; res., 2628 Garfield St., N. W., Washington, D. C.

Arnold, Oscar M., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

Aslaniar, Coffing W., Electrical Laboratory Man, Standardizing & Testing Depts., Boston Electric Illuminating Co., Boston, Mass.

*Bailey, George N., Asst. to Supt. of Steam Power, New England Power Co., 35 Harvard St., Worcester, Mass.

Bain, James W., Demonstrator in Elec. Engineering, McGill University, Montreal, Quebec, Canada.

Ball, Frederick Widmer, Electrical Instructor, Soldiers' Aid Commission, University of Toronto; res., 78 Herbert Ave., Toronto, Ont.

*Ballinger, John G., Electrician, Hydro-Electric Power Commission, Streetsville, Ontario, Can.

Bangs, Philip C., Junior Engineer (Transmission), Southern Bell Tel. & Tel. Co.; res., 29 Albemarle Ave., Atlanta, Ga.

Barcus, Miner, Draftsman, American Transformer Co., Newark; res., 20 Ivanhoe Terrace, East Orange, N. J.

*Barden, Harold E., Asst. Production Engineer, Southern California Edison Co., Edison Building, Los Angeles, Cal.

Barnes, Stanley M., Central Office Inspector, Michigan State Telephone Co.; res., 1086 Ellery St., Detroit, Mich.

Barney, Howard S., Dist. Supt., Chester County Light & Power Co., Kennett Square, Penn.

Barret, Charles E., Machinery Salesman, James Clark, Jr., Electric Co., 520 W. Main St., Louisville; res., Anchorage, Ky.

Barron, Edward F., Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

Barry, Thomas A., Engineering Dept., General Electric Co., 84 State St., Boston, Mass.

*Bayle, Russell M., Electrical Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1219 Mill St., Wilkinsburg, Pa.

Beard, Harry F., Electrical Foreman, American International Shipbuilding Corp., Hog Island, Pa.

Beechinor, Herbert M., Electrical Testing Laboratories, 80th St. & East End Ave., New York, N. Y.

Bendel, Emil H., Head of Engineering Dept., California Polytechnic School, San Luis Obispo, Cal.

Bender, Louis B., Captain, Signal Corps, U. S. A.; res., 34 Rodman St., Boston 30, Mass.

Benjamin, Webster W., Power Engineer, Western Light & Power Co., Boulder, Colo.

Bennett, Rolland H., Division Transmission Engineer, The Pacific Tel. & Tel. Co., San Francisco, Cal.

Bergen, Harold B., Junior Engineer, Henry L. Doherty & Co., 60 Wall St., New York; res., 589 Putnam Ave., Brooklyn, N. Y.

Blackwell, William I., Sales Agent, General Electric Co., 627 State Mutual Bldg., Worcester, Mass.

Bland, Henry, Telephone Engineer, Central Office, Western Electric Co., Hawthorne; res., 1208 W. 64th St., Chicago, Ill.

Blue, Frederick R., Engineer, Plant Dept., New York Telephone Co.; res., 1180 President St., Brooklyn, N. Y.

Bodey, Norman A., Supt., Engineering Dept., William H. Luden Mfg. Corp.; res., 126 Windsor St., Reading, Penn.

Bolton, John I. N., General Engineering, 13 Clyde St., Toronto, Ont., Canada.

Bozzi, Mario T., Chief Electrician & Motor Expert, The Acme Wire Co.; res., 12 Lines St., New Haven, Conn.

Bradley, Francis H., Equipment Engineer, So. New England Telephone Co.; res., 462 First Ave., West Haven, Conn.

Bradner, James P., Major, A. S. A. P., Officer U. S. Army; res., 1912 R St., N. W., Washington, D. C.

Brodhun, Carl P., Asst. Gen. Sales Manager, Hazard Mfg. Co., Wilkes-Barre, Pa.

Broe, Edgar P., Dept. of Development & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

*Brooks, Forrest E., Telephone Engr., Engineering Dept., New York Telephone Co., 203 Broadway, New York, N. Y.

*Bryan, Cyril K., Testing Dept., General Electric Co., 119 Park Ave., Schenectady, N. Y.

*Burnett, William, Jr., Electrical Engineer, Peabody Coal Co., Mine 18, W. Frankfort, Ill.

Burrows, Walter G., Telephony Engineering, New York Telephone Co., 203 Broadway, New York, N. Y.

Carlson, Carl F., Supervisor, The Cortland Electric Co., Inc.; res., 1715 Woodbine St., Brooklyn, N. Y.

Carnachan, Robert S., Electrical Draftsman, Bureau of Yards & Docks, Navy Dept.; res., 1513 Meridian Place, N. W., Washington, D. C.

Carpenter, Leslie S., Telephone Engineering, New York Telephone Co., New York, N. Y.; res., Chatham, N. J.

Champlin, Franklin J., Engineer in charge, Voltage Regulator Dept., General Electric Co., Pittsfield, Mass.

Chapman, V. J., Testman, General Electric Co.; res., 141 Fairview Ave., Schenectady, N. Y.

Chesnut, Edward F., Chief Instructor, Applied Electricity, Dept. of Soldier's Civil Re-establishment; res., 71 Walker St., Toronto, Ont.

Chute, Norman T., Manager, Hartford Office, The Lincoln Electric Co., 54 Church St., Hartford, Conn.

Clark, Henry W., Senior Engineer, Potomac Electric Power Co.; res., 2020, "O" St., N. W., Washington, D. C.

Clarke, Albert H., Sales Engineer, Canadian General Electric Co. Ltd., 212 King St. West, Toronto. Ont.

Cleary, Leo H., Electrical Designing Draftsman, Bureau of Yards & Docks, Navy Dept.; res., 43 Rhode Island Ave., N. W., Washington, D. C.

Cleary, William J., Telephone Engineering, New York Telephone Co., New York; res., 70 So. 9th St., Brooklyn, N. Y.

Clements, Chauncey H., Cable Supervisor, Southern New England Telephone Co.; res., 25 Irving St., New Haven, Conn.

Cleon, Hyman, Laboratory Asst., Lubrication Div., Bureau of Standards, Washington, D. C.

*Cobb, Cecil C., Electrical Construction Foreman, Oklahoma Railway Co.; res., 209 W. 2nd St., Oklahoma City, Okla.
Collins, Everett B., Asst. Elec. Engineer, New England Power Co., 35 Harvard St., Worcester, Mass.
Collins, Raymond P., Supervisor of Maintenance, Southern New England Telephone Co., New Haven; res., 38 Glendale St., Whitneyville, Conn.
Comstock, William W., Junior Electrical Engineer, Public Service Commission, 1st Dist., 49 Lafayette St., New York, N. Y.
*Conklin, Silas H., Asst. Electrical Engineer, Bureau of Standards, Washington, D. C.
Cooper, Geoffrey T., Checker of Electrical Design, Harry M. Hope Engineering Co., 185 Devonshire St., Boston, Mass.
Cowles, Willard B., Radio Research Laboratory, Connecticut Tel. & Elec. Co., 464 Colony St., Meriden, Conn.
Cox, Louis T., Development Engineer, (Auto Telephone), Western Electric Co.; res., 562 W. 144th St., New York, N. Y.
Creasey, John W., District Inspector, American Tel. & Tel. Co., 204 Telephone Bldg., Kansas City, Mo.
Cromwell, George F., Transmission & Protection Engineer, Wisconsin Telephone Co., 418 Broadway, Milwaukee, Wis.
*Crump, Samuel Lee, Electrical Engineer, Denver Gas & Electric Light Co., Denver, Colo.
Cuff, Paul S., Draftsman, New York Edison Co.; res., 200 W. 109th St., New York, N. Y.
Darling, Charles W., Officer in charge, Marconi Station s/s Hochelaga; Marconi Wireless Tel. Co. of Canada, 173 William St., Montreal, Canada.
Davis, Albert I., Construction Foreman, West Penn Power Co.; res., 225 Painter St., Greensburg, Pa.
Davis, C. I., Asst. Inspector, Public Service Co. of Northern Illinois, 911 Church St., Evanston, Ill.
Day, Bernhard F. J., Managing Director, The Day Engineering Bureau, Thanet House, Strand, London, Eng.
*Deane, Tsung Yao, Telephone Engineer, China Electric Co., Shanghai, China.
Dennison, Allan, Foreman Electrician, Canadian Explosives Ltd., Nobel, Ontario, Can.
De Nyse, Charles R., Jr., Substation Operator, United Electric Light & Power Co., New York; res., 1836 Church St., Richmond Hill, N. Y.
De Penning, Victor H., Electrician, E. L. Knight Electric Co., 449 Washington St.; res., 141 E. 34th St., Portland, Ore.
Dodge, John W., Division Equipment Inspector, Western Union Telegraph Co., Bankers Investment Bldg., San Francisco, Cal.
*Dorpat, Martin H., Designer of Manual Control Apparatus, Cutler-Hammer Mfg. Co., 12th & St. Paul Sts., Milwaukee, Wis.
Dortch, G. L., Merchant, Planter & Engineer, Power Equipment Co., 213 E. Markham St., Little Rock, Ark.
*Drake, Charles P., Supt., Edison Steam Plant, Wis-Minn. Light & Power Co., La Crosse, Wis.
Droesch, Louis A., Instructor, Dept. of Electrical Engineering, Stevens Institute of Technology, Hoboken, N. J.
Duncan, P. M., Electrical Engineer, Allis-Chalmers Mfg. Co., West Allis; res., 3631 Park Hill Ave., Milwaukee, Wis.
Duncan, William Bryan, Draftsman, San Joaquin Light & Power Corp., Bakersfield, Cal.
Dunton, Ernest W., Chief Electrical Engineer, Anglo-Saxon Petroleum Co. Ltd., London, England; res., Miri, Singapore, India.
Eales, Malcolm A. L., Asst. to Operating Engineer, New England Power Co., Worcester; res., 4 Chestnut Park, Melrose, Mass.
Ebaugh, John H., Sales Representative, Allis-Chalmers Mfg. Co., Denver, Colo.
Edgerton, Rupert L., General Toll Wire Chief, Southern New England Telephone Co.; res., 42 William St., New Haven, Conn.
Ehlers, Paul, Chief Electrician, Zimmerman Steel Co., Bettendorf; res., 619 Gaines St., Davenport, Iowa.
Elebash, Karl S., Electrical Engineer & Contractor, Elebash Elec. Co., Tuscaloosa, Ala.
English, Charles L., Electrical Engineer, Ansonia Electrical Co.; res., 70 So. Cliff St., Ansonia, Conn.
Eshelman, Paul B., Electrical Engineer, Fidelity Electric Co., 332 N. Arch St., Lancaster, Pa.
Fay, Richard D., Associated with H. V. Hayes, 84 State St., Boston; res., 20 Coolidge Hill Road, Cambridge, Mass.
Ferguson, Muirhead T., Electrical Asst. to Plant Engineer, Halifax Shipyards, Ltd.; res., 55 Cornwallis St., Halifax, N. S.
Ferry, James H., Electrical Engineer, Potomac Electric Power Co., 231-14th St., N.W., Washington, D. C.
Flath, Earl H., Asst. Professor of Physics and Electrical Engineering, University of Alabama, University, Ala.
Flynn, William N., Plant Electrician, Atlantic Corp., Portsmouth; res., 7 Hancock St., Dover, N. H.
Fogelsong, Elmer B., Asst. Manager, Chandeysson Electric Co., 4092 Bingham Ave., St. Louis, Mo.
Ford, Fred S., Instructor, Power & Circuit, Western Electric Co., Inc., 402 W. 7th St., Wilmington, Del.
Foy, Bertrand A., Chief Draftsman, Potomac Electric Power Co., 14th & C Sts., N. W., Washington, D. C.
*Freehafer, Fred K., Engineering Asst., The Bell Telephone Co. of Penn., Philadelphia; res., Lansdowne, Pa.
French, F. D., Dist. Manager, The Lincoln Electric Co., 846 Ellicott, Square, Buffalo, N. Y.
Furuki, Masumitsu, Student Engineer, Testing Dept., General Electric Co., Schenectady; res., Scotia, N. Y.
Gaffney, Joseph F., Technical Asst., Electrical Testing Laboratories, 80th St. & East End Ave., New York, N. Y.
Garrett, Curtis L., Engineering Assistant, C. & P. Telephone Co.; res., 4019 Forest Park Ave., Baltimore, Md.
Gass, Thomas A., Sales Manager, Canada Wire & Cable Co., Ltd., Toronto, Ont.
George Everett E., Valuation Engineer, A. L. Drum & Co., Chicago; res., 230 N. 2nd St., Highland Park, Ill.
*Gibson, Archie B., Manager, Casino Technical Night School, E. Pittsburgh, Pa.
Gillett, Francis E., Supt., The Depew & Lancaster Light, Power & Conduit Co.; res., 12 Holland Ave., Lancaster, N. Y.
*Glasgow, Roy S., Instructor in Electrical Engineering, Washington University; res., 3966 Arsenal St., St. Louis, Mo.
*Godshalk, Ernest L., Engineering Dept., Counties Gas & Electric Co., 212 De Kalb St., Norristown, Pa.
Goldberg, Israel, Electrician, Hughes Electric Heating Co.; res., 9 Beatrice St., Toronto, Ont.
Goldsman, Jack L., Radio Engineer, Emil J. Simon, 217 Broadway, New York, N. Y.
*Goldston, Leonard, Senior Student in Elec. Engg., Brooklyn Polytechnic Institute; res., 117 So. 4th St., Brooklyn, N. Y.
Golladay, Lawrence R., Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1435 Penn Ave., Wilkinsburg, Pa.
Goodnough, Rex E., Central Office Engineer, Western Electric Co., Hawthorne; res., 5122 W. 24th Place, Cicero, Ill.
Grasle, Wesley R., E. L. Knight & Co., 449 Washington St., Portland, Ore.
Gregory, William H., Asst. Engineer, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.
Hall, Albert I., Electrical Engineer, General Electric Co.; res., 50 Bartlett Ave., Pittsfield, Mass.
Ham, Frank L., President, Delta Electric Co., 658 Main St., Worcester, Mass.
*Haman, Donald A., Instructor, Pratt Institute, Brooklyn, N. Y.
Harrison, William H., Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
Hartman, Fred, Chief Electrician, Cumberland Coal Co., Albert, Tucker Co., W. Va.
*Hartung, Arthur E., Sales Engineer, Century Electric Co.; res., 5352 Vernon Ave., St. Louis, Mo.
Hastings, Milton B., Secretary & Sales Engineer, A .H. Winter Joyner Ltd., 100 Wellington St. W., Toronto, Ont.
*Hawker, Clifford F., Asst. Electrical Engineer, Dayton Power & Light Co., Dayton, Ohio.
Hecker, Arthur D., Electrical Foreman, American International Shipbuilding Corp., Hog Island, Pa.
Hemenway, Robert A., Meter tester, Worcester Electric Light Co.; res., 22 Davidson Road, Worcester, Mass.
Henderson, John W. G., Draftsman, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
*Herrle, Jacob N., Jr., Asst. Foreman, Metropolitan Engineering Co.; res., 664 Madison St., Brooklyn, N. Y.
Hickey, Charles E., Supt. of Interior Construction, N. Y. & Queens Electric Light & Power Co., Bridge Plaza, Long Island City, N. Y.
Hill, Clarence, Elec. Foreman, American International Shipbuilding Corp., Hog Island, Pa.
Hill, Harold C., Motor Specialist, International General Electric Co., Inc.; res., 126 Parkwood Blvd., Schenectady, N. Y.
Hine, Donald F., Student, Graduate School, Yale University, 70 Trumbull St., New Haven, Conn.
Ho, Molin, Graduate Student, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 329 Barnes St., Wilkinsburg, Pa.

HOARE, STEPHEN C., Standardizing Laboratory, General Electric Co.; res., 80 Park St., W. Lynn, Mass.
HODGES, FRANK E., Engineer, New York Telephone Co., 15 Dey St., New York, N. Y.
HOELZLE, FRANK C., Chief Electrical Draftsman, New York Shipbuilding Corp., Camden, N. J.
HOKE, CHARLES C., Junior Engineer, Union Electric Light & Power Co.; res., 3812 Castleman Ave., St. Louis, Mo.
HOLIHAN, THOMAS D., Electrical Sales Engineer, Syracuse Lighting Co., 335 S. Warren St., Syracuse, N. Y.
HOLLIDGE, GEORGE M., Construction Foreman, San Francisco Dist., Pacific Gas & Electric Co., 1822 San Antonia Ave., Alameda, Cal.
HOUSTON, ROBERT, Resident Electrical Engineer Water Conservation & Irrigation Commission, Leeton, N. S. Wales, Australia.
*HOYLE, EARLE R., Electrician, Texas Construction Co., Interurban Bldg., Dallas, Texas.
HUFF, BENJAMIN L., Distribution Engineer, Consumers Power Co.; res., 202 Palmer Avenue, Jackson, Mich.
HUGHES, RUSSELL H., Engineering Asst., New York Telephone Co., 15 Dey St.; res., 438 W. 116th St., New York, N. Y.
HUYLER, ROLLIN M., Electrical Construction Man, United Electric Light & Power Co., 514 West 147th St., New York, N. Y.
HYMANS, FREDERICK, Engineer with Otis Elevator Co., 11th Ave. & 26th St., New York, N. Y.; res., Glen Ridge, N. J.
IRWIN, J. HARVEY, Salesman, Aluminum Company of America, 1500 Westminster Bldg., Chicago, Ill.
JAMES, EARL S., Chief Electrician, Oklahoma Gas & Electric Co., 18-20 W. Noble, Oklahoma City, Okla.
JEANNE, PAUL A., Asst. Electrical Engineer, Mountain States Tel. & Tel. Co., Denver, Colo.
JENKINS, JOHN R., Service Dept., Cutler-Hammer Mfg. Co., New York; res., 715 Lott Ave., Union Course, N. Y.
JESSEN, CHRISTIAN, Chief Electrical Mechanic, Bureau of Illumination, City of Milwaukee; res., 659 New York Ave., Milwaukee, Wis.
*JOHNSON, ROBERT H., Sales Engineer, National Carbon Co., 431 S. Dearborn St., Chicago, Ill.
JONES, BENSON M., General Engineering Division, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
JONES, CARL H., Lieutenant, U. S. Navy; res., 2465 Broadway, New York, N. Y.
KARKER, EARL C., Instructor of Physics & Electricity, Univ. of Rochester; res., 151 Genesee St., Rochester, N. Y.
KARLSEN, EDWARD V., Electrician, Union Gas & Electric Co., West End Station, Cincinnati, Ohio.
KELLE, ARTHUR C., Electrical Engineer, 75 State St., Boston; res., 26 Dana Ave., Hyde Park, Mass.
KENNEDY, CLIFFORD W., Research Engineer, M. S. Wright Co.; res., 8 Oberlin St., Worcester, Mass.
KIMBALL, MERRILL J., Division Switchboard Engineer, Traffic Dept., Pittsburgh Div., The Bell Telephone Co. of Penn., 416 7th Ave., Pittsburgh, Pa.
KING, IRVING CLARENCE, System Operator, Empire Gas & Electric Company, Auburn, N. Y.
KITA, ICHIMATSU, Testing Dept., General Electric Co., Schenectady; res., 147 Riverside Ave., Scotia, N. Y.
*KODIL, CHARLES E., Operator, Bureau of Power & Light, City of Los Angeles, Cal.
*LEE, EWE AIK, 309 E. Garfield Boulevard, Chicago, Ill.
LEGG, JOSEPH W., Electrical Engineer, (Research & Development) Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
LEXA, GEORGE J., Asst. Electrical Engineer, Pawling & Harnischfeger Co.; res., 1056 25th St., Milwaukee, Wis.
*LINCOLN, JOHN C., Foreman of Construction work, Delco-Light Co.; res., 411 Buttles Ave., Columbus, Ohio.
*LITTLEFIELD, MAURICE G., Thompson Electric Welding Co., Lynn; 33 Cedar Hill Terrace, Swampscott, Mass.
*LIVERGOOD, HOMER, Elec. Constr. Foreman, Engineering Dept., General Electric Co., Witherspoon Bldg., Philadelphia, Pa.
LOCKERBIE, EARL M., Branch Manager, Lincoln Electric Company of Cleveland, Ohio, 721 University Bldg., Syracuse, N. Y.
LOHR, HERMAN, Director of the "N. V. Provinciale Geldersche Ekectriciteits Maatschappy" Utresctsche stratt, Arnhem, Holland.
LOWRY, RAY S., Electrical Engineer, Newton Steel Co., Newton Falls, Ohio.
LOYNES, OWEN H., Electrical Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
LUKE, GEORGE E., Railway Motor Design Section, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
LUNNY, JAMES E., Buyer, W. R. Grace & Co., New York; res., 508 16th St., Brooklyn, N. Y.
KNIGHT, HENRY A., Supervisor of Wires, City of Worcester, 11 City Hall, Worcester, Mass.
KRUEGER, CARL H., Transmission & Protection Engineer, Wisconsin Telephone Co., 418 Broadway, Milwaukee, Wis.
KUHN, PAUL R., Electrical Engineer, Penn. Central Light & Power Co.; res., 813 Green Ave., Altoona, Pa.
KUMEILIKE, LORENZ LEI, Radio Electrician (First class), U. S. Naval Radio Laboratory, Mare Island; res., 942 Third St., Napa, Cal.
LAMPE, J. HAROLD, Electrical Engineer, Winchester Repeating Arms Co., 16 York Square, New Haven, Conn.
*LANKTON, WILLIAM W., Foreman in Charge of Electrical Dept., Detroit Copper & Brass Rolling Mills; res., 619 Hubbard Ave., Detroit, Mich.
LAPLANTE, ERNEST G., Electric Installation & Maintainence, Wood Electric Construction Co., Lynn, Mass.
*LA ROQUE, HAROLD B., Graduate Student, Yale University, 68 Whalley Ave., New Haven, Conn.
LASH, LELAND E., Supt., Oklahoma Gas & Electric Co., 112 N. Broadway, Oklahoma City, Okla.
LASKEY, WILLIAM G., Engineer, Western Electric Co. Inc., 463 West St., New York, N. Y.
LAW, CLARENCE L., Manager, Bureau of Illuminating Engineering, N. Y. Edison Co., Irving Place & 15th St., New York, N. Y.
LAWRENCE, ROGER C., Electrical Engineer, American Steel & Wire Co., 94 Grove St., Worcester, Mass.
LAYCOCK, CHARLES H., Radio Draftsman, U. S. Navy Yard, 9 Blackwood St., Boston, Mass.
LEBO, WILLIAM F., Engineer, Public Service Comm. of Indiana; res., 1037 N. Belleview Place, Indianapolis, Ind.
LYON, WILLIAM R., Instructor in Electrical Engineering, University of Wisconsin, Engineering Bldg., Madison, Wis.
MADDOCK, EDWIN C., Supt., Electrical Construction, Chevrolet Motors, Oshawa, Ontario, Can.
MASON, DONALD T., P. B. X. Repairman, Central Union Telephone Co.; res., 94 Wick Place, Youngstown, Ohio.
MCCHESNEY, ROBERT W., District Manager, Harry Alexander, Inc.; res., 827 8th St., N. E. Washington, D. C.
MCCORDICK, ARTHUR S., Sales Engineer, Canadian General Electric Co., 212 King St. West, Toronto Ontario.
MCKERROW, ALAN DRUMMOND, Electriacl Designer, New England Power Co., 35 Harvard St., Worcester, Mass.
MCLAREN, DUNCAN L., Engineering Dept., Canadian General Elecrtic Co., Ltd.; res., 291 Stewart St., Peterboro, Ont.
MCORLLY, JOSEPH, Draughtsman in Charge of Development Section, Railway & Industrial Engineering Co., Greensburg, Pa.
*MILLER, CHARLES A., Meterman, Light Dept., City Hall, Tacoma, Wash.
MITZENIUS, WALTER L., Electrical Engineer, New York & Queens Elec. Lt. & Pr. Co., Bridge Plaza, Long Island City, N. Y.
MUNOZ, ALPHONSE, Armature Winder, General Chemical Co.; res., Overlook Colony, Claymont, Del.
*MURATA, MOTOSABURO, 102 West 123rd St., New York, N. Y.
*NAYLOR, JOHN M., Draftsman, The Millville Mfg. Co.; res., 303 High St., Millville, N. J.
NEAHR, WILL C., Electrical & Designing Engineer, The Protective Signal Mfg. Co., 1429 18th St., Denver, Colo.
NEWMAN, WILLARD L., Telephone Equipment Engineering, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
OLDHAM, EDWARD C., Electrical Engineering, New England Power Co., 35 Harvard St., Worcester, Mass.
O'NEIL, WILLIAM J., Chief Operator, Margaret St. Substation, Turners Falls Power & Electric Co., Springfield, Mass.
O'NEILL, FRANK H., Chief Electrician, Monongahela Valley Traction Co.; res., Y. M. C. A., Fairmont, W. Va.
OSBURN, WILLIAM, Floor Electrician & Foreman of Construction of Central Station, Union Gas & Electric Co., Cincinnati, Ohio.
OVERBEY, FRANK E., Service & Inspection, Cutler-Hammer Mfg. Co., 50 Church St., New York, N. Y.
PACKARD, ANSEL A., Superintendent, The Connecticut Power Co., Middletown, Conn.
PARMER, MARION CURTIS, Chief Electrician, Beech Bottom Power Co. Wheeling; res. Wellsburg, W. Va.
PATTERSON, CHARLES L., Designer of Electrical Machinery, Fessenden Engineering Laboratory, 185 Franklin St., Boston, Mass.
PAYNE WILLIAM H., Engineer, The Pittsburgh Electric Furnace Corp., Pittsburgh; res., Carnegie Hotel, Clariton, Pa.
PENDER, PAUL S., Erecting Engineer, Printing Equipment Dept., The Cutler-Hammer Mfg. Co., Milwaukee, Wis.
PENNINGTON, JOHN F., Tester, Construction Dept., Georgia Railway & Power Co., 445 Electric & Gas Bldg., Atlanta, Ga.
PERKINS, E. EVERETT, JR., Tester, Westinghouse Elec. & Mfg.

Co., E. Pittsburgh; res., 419 Whitney Ave., Wilkinsburg, Pa.
Petrie, Albert E., Telephone Engineer, Western Electric Co., 463 West St., New York, N. Y.; res., E. Orange, N. J.
*Pette, Allen D., Asst. Steam & Elec. Engineer, International Harvester Co., McCormick Works; res., 2135 W. Adams St., Chicago, Ill.
Phelps, Leverne R., Electrical Supt., Atlas Crucible Steel Co.; res., 412 Mullett St., Dunkirk, N. Y.
Phillips, Charles O., Electrical Draftsman, Stone & Webster Co., 916 Chestnut St., Philadelphia, Pa.
Phinney, Harry L., Equipment Engineer, The Pacific Tel. & Tel. Co., 461 Market St., San Francisco, Cal.
Plaisance, Stanley F. X., Construction Foreman, General Electric Co., Monadnock Block, Chicago, Ill.
Polachek, Zoltan H., Manager, Manufacturers Engineering Co., 1133 Broadway, New York, N. Y.
Pope, Harry M., Commercial Engineering Dept., New York Telephone Co., 15 Dey St., New York, N. Y.
*Postles, Findlay J., Electrical Instructor, New York Electrical School, 39 W. 17th St., New York, N. Y.
Poston, Virgil, Supt. of Operation, New York & Queens Electric Light & Power Co., Bridge Plaza, Long Island City, N. Y.
Pottinger, Clarence A., Electrical Engineer, Bureau of Illuminating Service, City of Milwaukee, City Hall, Milwaukee, Wis.
Powell, Joel W., Telephone Engineer, The Pacific Tel. & Tel. Co., 620 Sheldon Bldg., San Francisco, Cal.
Prosser, William E., Industrial Heating Engineer, Union Electric Light & Power Co., St. Louis, Mo.
Purinton, Ralph B., Electrical Engineer, General Electric Co., Monadnock Bldg., Chicago, Ill.
Ranges, John E., Engineer, Western Electric Co., 463 West St.; res., 79 Jane St., New York, N. Y.
Rathke, C. George, Draftsman, Connecticut Light & Power Co.; res., 31 Central Ave., Waterbury, Conn.
Reese, Clarence B., Gen. Electrical Foreman, Construction Dept., Braden Copper Co., Rancagua, Chile, S. A.
Reich, Walter J., Wire & Cable Engineering, General Electric Co., Schenectady; res., 365 Guy Park Ave., Amsterdam, N. Y.
Richardson, Simeon W., with F. R. Weller, 503 Hibbs Bldg., Washington, D. C.
Rives, Tom C., Asst. City Electrician; res., 214 Grove St., Montgomery, Ala.
Roberts, Clinton V., Electrical Construction Dept., General Electric Co.; res., 724 Rosedale Ave., Erie, Pa.
Rocchetti, Joseph, Chief Engineer, Manitoba Power Commission, New Parliament Bldgs., Winnipeg, Manitoba.
Rosenzweig, Fred M., Engineer, Roth Bros. & Co., Adams & Loomis Sts., Chicago, Ill.
Runyon, William McCurdy, Chief Inspector, E. V. Hartford, Inc., 143 Morgan St., Jersey City; res., Stelton, N. J.
Rusmissell, Charles T., Chief Electrician, McDowell Coal & Coke Co., McDowell, W. Va.
*Rutan, Everett J., Foreman, Test Dept., N. Y. Edison Co., New York; res., 4630 Ridge Ave., Glen Morris, N. Y.
*Ryan, Clarke L., Construction Engineer, Nebraska Telephone Co.; res., 606 N. 33rd St., Omaha, Neb.
Salt, Lloyd B., Asst. Research Engineer, B. F. Sturtevant Co., Hyde Park; res., 11 Van Brunt Ave., Dedham, Mass.
*Sawyer, Leon G., Electrical Engineer, Eisemann Magneto Co.; res., 463 40th St., Brooklyn, N. Y.
Sawyer, Lee A., Field Engineer, Research Corporation, 63 Wall St., New York, N. Y.
Scheffer, Robert E., Student Engineer, General Electric Co.; res., 244 Union St., Schenectady, N. Y.
Schelleng, John C., Engineering Dept., Western Electric Co., 463 West St., New York, N. Y.
Schwarberg, Harry J., Foreman, Substation, Union Gas & Electric Co., 4th & Plum St., Cincinnati, Ohio.
Selzer, Carl A., Chief Electrician, Leeds & Northrup Co. of Philadelphia, 4901 Stenton Ave., Philadelphia, Pa.
Shaffer, Irwin, Electrical Designing Engineer, B. F. Goodrich Co., Akron; res., 235 S. 3rd St., Cuyahoga Falls, Ohio.
*Sheadel, James B., Supt., Traction, Light & Power Co.; res., 1511 Arrow Ave., Anderson, Ind.
Shechtell, Joseph, Electrical Tester, Edison Electric Illuminating Co. of Boston, 1165 Massachusetts Ave., Boston, Mass.
Sherrerd, George, Jr., Commercial Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Sinner, Harry C., Chief Electrical Maintenance Engineer, Bergner & Engel Brewing Co.; res., 1330 N. Dover St., Philadelphia, Pa.
Smith, J. Frank, District Manager, Blackmer Rotary Pump Co., 1119 Real Estate Trust Bldg., Philadelphia, Pa.
Smith, John F., Tester, The United Electric Light & Power Co.-New York; res., 2406 Bedford Ave., Brooklyn, N. Y.
Spero, B. E., President, Spero Electrical Mfg. Co., E. 33rd & Woodland Sts., Cleveland, Ohio.
Sprague, Arthur B., Foreman, Testing Dept., Worcester Electric Light Co., 66 Faraday St., Worcester, Mass.
Stayner, Charles M., Supt. of Lines & Substations, Bamberger Electric Railroad, Salt Lake City; res., Farmington, Utah.
Stein, Rudolph H., Quarterman Instrument Maker, Navy Yard, New York; res., 589 98th St., Woodhaven, N. Y.
Stevens, John C., Consulting Hydraulic Engineer, Spalding Building, Portland, Ore.
Stier, H. Douglas, District Sales Manager, Railway & Industrial Engineering Co. 602 Monadnock Block, Chicago, Ill.
Stone, J. Waldo, Sales Agent, General Electric Co., New York, N. Y.; res., 9 Carteret St., Upper Montclair, N. J.
Suydam, William H., Jr., Tester, New York Edison Co., 92 Vandam St., New York; res., 645 Delaware Place, Brooklyn, N. Y.
Templeman, Daniel R., Asst. in Research Dept., M. S. Wright Company; res. 63 Charlotte St., Worcester, Mass.
*Terrell, Phillip A., Electrician, Alabama Power Co.; res., 1114 Tuscaloosa Ave., W. E., Birmingham, Ala.
*Teschner, Albert, In Charge of Elec. Construction & Maintenance, The Texas Co., Bayonne, N. J.
Thompson, Thomas C., Factory Manager, Automatic Electric Co., 1001 W. Van Buren St., Chicago, Ill.
Tillman, Stephen J. N., Chief Electrician, Old Dominion Copper Co., Globe, Ariz.
Tobiessen, Emanuel, Electrical Engineer, Allis-Chalmers Mfg. Co.; res., 774, 74th Ave., West Allis, Wis.
Tornquist, Earl L., Asst. Inspector, Public Service Co. of Northern Illinois, 230 N. Genesee St. Waukegan, Ill.
Townsend, George L., 1st Lieut., Officer in Charge, Signal Corps Research Laboratory, Bureau of Standards; res., 98 Chestnut St., Washington, D. C.
*Townsend, Wisner R., Purchasing Dept., American Sugar Refining Co.; res., 420 W. 116th St., New York, N. Y.
Trojan, Ervin J., Asst. Testing Engineer, Commonwealth Edison Co., 28 No. Market St., Chicago, Ill.
Truman, Joseph K., Power Plant Operator, (Canyon Ferry Plant), Montana Power Co., Canyon Ferry, Mont.
Tsujii, Makoto, Engineer, Furukawa & Co. Ltd., 120 Broadway, New York, N. Y.
Tyler, Charles H., Electrical Construction, U. S. Naval Ordnance Plant, South Charleston, W. Va.
Van Horn, Alfred R., Designing Engineer & Inventor, Trumbull Electric Mfg. Co., Plainville, Conn.
Van Thun, James R., Electrical Leaderman, American International Shipbuilding Corp., Hog Island; res., 1516 N. 27th St., Philadelphia, Pa.
Walter, Hollis, Asst. Stabilizer Engineer, Sperry Gyroscope Co., Manhattan Bridge Plaza, Brooklyn, N. Y.
Wegel, Raymond L., Western Electric Co., Inc., 463 West St., New York, N. Y.
Welch, Paul V., Engineer, Dept. of Development & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
Weller, Clifford T., Electrical Engineer, General Engineering Laboratory, General Electric Co., Schenectady, N. Y.
Wenzel, August F., Telephone Engineer, Rochester Telephone Co.; res., 385 Parsells Ave., Rochester, N. Y.
White, Allan Joseph, Transmission & Protection Engr., Southwestern Bell Tel. Co., Little Rock, Ark.
Whitehurst, Roland, Sales Engineer, Electric Storage Battery Co.; res., 2024 Morris Ave., New York, N. Y.
Wilcox, Harry K., Electrician, Gillespie Motor Co.; res., 341 Getty Ave., Paterson, N. J.

*Former enrolled student.

ASSOCIATES RE-ELECTED APRIL 9, 1920

FRIEND, LEONARD, Electrical Foreman, Toledo Shipbuilding Co.; res., 1022 Superior St., Toledo, Ohio.
LEE, EVERETT S., Engineer, General Engineering Laboratory, General Electric Co.; res., 967 Maple Ave., Schenectady, N. Y.
KERR, DAVID J., Supt. of Power, Champion Fibre Co., Canton, N. C.
MYERS, ALEXANDER M., Chief Electrician, Standard Underground Cable Co., Perth Amboy, N. J.
MOORE, CHARLES R., Telephone Engineer, Western Electric Co., 463 West St., New York, N. Y.
WATERHOUSE, JAMES K., Supt., L. I. City Dist., New York & Queens Elec. Lt. & Pr. Co., Queens Plaza North, Long Island City, N. Y.
YOUNG, RUSSELL, Resident Engineer, Atlantic Refining Co.; res., 717 So. Frazier St., Philadelphia, Pa.

MEMBERS ELECTED APRIL 9, 1902

BECHTOL, HARVEY W., Brush Engineer, National Carbon Company, Inc., Cleveland, Ohio.
BROWN, LEWIS B., Asst. to Chief Draftsman, Public Service Electric Co., Newark; res., Chatham, N. J.
BROWN, WENDELL S., Engineer, F. P. Sheldon & Son, 1009 Hospital Trust Bldg., Providence, R. I.
DAVIES, STANLEY F., Consulting Electrical Engineer, 101 Park Ave., New York, N. Y.
EDWARDS, JOHN H., Electrical Engineer, Elkhorn Piney Coal Mining Co., 211 Robson-Prichard Bldg., Huntington, W. Va.
HAMMOND, WILLIAM P., Asst. Engineer, Georgia Railway & Power Co., Atlanta, Ga.
JAMES, BERTRAM, Sales Engineer, Moloney Electric Co. of Canada, Ltd., Toronto, Ont.
JEFFERY, JOSEPH A., President, Jeffery-Dewitt Co.; and Jeffery-Dewitt Insulator Co., Detroit, Mich.
*JOHNSON, LEWIS H., Systems Development Engineer, Western Electric Co., Inc., 463 West St., New York, N. Y.; res., Madison, N. J.
*LEONARD, RUSSELL E., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
LEONIDA, DIMITRIE, General Manager, "Energia," & Director "Scoala de Electricioni & Mechanici," Str. Salcamilor 11, Bucharest, Roumania.
MASEK, JAMES C., Electrical Engineer, Cutler-Hammer Mfg. Co.; res., 724, 51st St., Milwaukee, Wis.
O'HARA, GEORGE D., Consulting Engineer, O'Hara & Shaw, 1015-17 Phelan Bldg., San Francisco, Cal.
PIGMAN, GEORGE R., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
RICHARDSON, FRANK D., Engineer, Inside Plant, Long Lines Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
SHANNONHOUSE, GEORGE G., Electrical Engineer, Du Pont Engineering Co., Wilmington, Del.; res., 435 Woodward Ave., Detroit, Mich.
*SMITH, HARRY A., Division Traffic Engineer, Western Union Telegraph Co., 914 Transportation Bldg., Atlanta, Ga.
SPATES, THOMAS G., Asst. to Gen. Supt., New York & Queens Elec. Lt. & Pr. Co., Elec. Bldg., Bridge Plaza North, Long Island City, N. Y.
WOLLEY, CHARLES E., Supt. of Factory & Vice-President, James Clark Jr. Electric Co.; res., 1014 Everett Ave., Louisville, Ky.
* Former enrolled students

FELLOWS ELECTED APRIL 9, 1920

McLEER, CHARLES B., Engineer, Electric Transport Co., 165 Broadway, New York, N. Y.
THOMAS, JAMES WINTHROP, Engineer, United Gas & Electric Engg. Corp., 61 Broadway, New York, N. Y.

TRANSFERRED APRIL 9, 1920

To Grade of Fellow

BLISS, LOUIS D., President, Bliss Electrical School, Takoma Park, Washington, D. C.
GRAY, CLYDE D., Electrical Engineer, J. G. White Engineering Corp., New York, N. Y.

To Grade of Member

BOYKIN, RICHARD M., Vice-President and General Manager, North Coast Power Co., Portland, Ore.
CANDY, ALBERT M., General Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
GASKILL, WALTER W., Consulting and Sales Engineering, Boston, Mass.
HAYES, CLIFTON R., Engineering Manager, Charles H. Tenney & Co., Boston, Mass.
HENKLE, JOSEPH C., Supt. Meters & Construction, Portland Railway, Light & Power Co., Portland, Ore.
HOFFMANN, CHARLES B., Assistant Professor of Electrical Engineering, University of Cincinnati, Cincinnati, O.
JOHNSTON, A. LANGSTAFF, JR., Lt. Comdr., U. S. N. R. F., Senior Asst. Inspector of Machinery, U. S. Navy, Newport News, Va.
KARTAK, FRANZ A., Professor of Electrical Engineering, School of Engineering of Milwaukee, Milwaukee, Wis.
LAMB, GILBERT C., Electrical Engineer, Engineering Div., E. I. du Pont de Nemours & Co., Wilmington, Del.
NOYES, JOHN D., Sales Engineer, Detroit Edison Co., Detroit Mich.
PECK EMERSON P., Gen'l Supt. Elec. Dept. Utica Gas & Electric Co., Utica, N. Y.
THOMAS, GEORGE N., Electrical Engineer, Canadian General Electric Co. Ltd., Toronto, Ont.
WERWATH, OSCAR, President, School of Engineering of Milwaukee, Milwaukee, Wis.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at a meeting held on April 6, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

FRASER, DANIEL M., Estimating Engineer, Canadian General Electric Co. Ltd., Toronto, Ont.
SNOOK, H. CLYDE, Electrical Engineer, Western Electric Co., New York, N. Y.

To Grade of Member

BAKER, HENRY S., In Charge Detail Apparatus, Ontario Power Co., Niagara Falls, Ont.
BENNETT, CLAUDIUS E., Asst. Chief Engineer, Riegos y Fuerzo del Ebro, Barcelona, Spain.
BENSON, ROBERT J., Power Engineer, Wagner Electrical Mfg. Co., St. Louis, Mo.
CLINGERMAN, BYRON H., Managing Power Engineer, B. F. Goodrich Co., Akron, O.
DU VALL, W. CLINTON, Associate Professor of Electrical Engineering, University of Colorado, Boulder, Colo.
GROWDON, JAMES P., Asst. General Superintendent, Northwestern Electric Co., Portland, Ore.
GHOSH, SURENDRA N., Acting Chief Electrical Engineer, Tata Iron & Steel Co., Ltd., Jamshedpur, India.
JAMES, WILLIAM F., Sales Engineer, Westinghouse Electric & Mfg. Co., Philadelphia, Pa.
LOCKE, DEAN J., Electrical Engineer, with Albert S. Richey, Worcester, Mass.
LODYGUINE, ALEXANDER, Inspector Incoming Electrical Material, Sperry Gyroscope Co., Brooklyn, N. Y.
SARA, RICHARD A., Partner, C. A. Sara, Montreal, Que.
TODD, WILLIAM B., Asst. Electrical Engineer, E. I. du Pont de Nemours & Co., Wilmington, Del.
TUTTLE, ELBERT B., Asst. Engineer, Bell Telephone Co. of Pennsylvania, Philadelphia, Pa.
WATERHOUSE, JAMES K., Supt. L. I. City District, N. Y. & Queens Electric Light & Power Co., Long Island City, N. Y.
WHITNEY, RICH D., Associate Professor of Electrical Engineering, Syracuse University, Syracuse, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member, objecting to the election of any of these candidates should so inform the Secretary before April 30, 1920.

Alender, Walter A., Chicago, Ill.

THE CORONA VOLTMETER AND THE ELECTRIC STRENGTH OF AIR

(*Continued from page 444*)

(*c*) *Comparison of Kenotrons with Commutator*. With the connections shown in Fig. 1, since the kenotron conducts in only one direction, the galvanometer receives a unidirectional pulsating current, the successive pulses being separated by time intervals of one-half period. The same conditions may be obtained in the galvanometer by the method shown in Fig. 3, the resistance R_1 being connected straight to ground and the synchronous commutator being connected as a shunt suppressor, *i. e.*, so that the galvanometer is short-circuited during alternate half-cycles. With fixed conditions in the high-tension circuit therefore both these methods should give the same galvanometer reading. In the experiments recorded in the following Table II, the voltage was set at the corona-forming value for a 0.955-cm. (0.376-in.) diameter rod in the corona voltmeter, for each of the two wave forms pertaining to the two methods of connection of the transformer primaries. The table gives for each method of connection first the readings leading to the commutator setting for maximum galvanometer deflection, and this is done using the galvanometer both as complete rectifier and as half-wave suppressor. It is seen that these two sets of readings are closely in the relation 2 to 1, and that the commutator setting is indicated to within one and one-half electrical degrees. The readings at maximum setting are then given and directly below them the corresponding kenotron readings. It is seen that there is excellent agreement particularly when the full rectification readings are included. A further interesting observation was made in connecting the galvanometer and commutator as shunt suppressor across each of the resistances R_1 and R_2 of Fig. 1 in turn, using the maximum brush settings and other conditions of Table II. For one of the resistances the full galvanometer deflections of Table II were obtained, but for the other the mean of the right and left readings of the galvanometer was accurately zero, as is to be expected since for the half wave during which the kenotron conducts the galvanometer is short-circuited by the commutator. This observation also indicates the absence of reverse currents due to inequalities in the voltage wave.

TABLE II.
COMPARISON OF READINGS WITH KENOTRONS AND WITH COMMUTATOR.

(*d*) *Calibration of Galvanometer*. The galvanometer used for measuring the charging current of the air condenser was a late American type d'Arsonval read by telescope and scale. Its constants were as follows: resistance 115 ohms; sensitivity 40 megohms; free period 9.5 seconds; critical damping resistance 560 ohms. Throughout all the observations the galvanometer was shunted with 560 ohms and the combination used in series with 10^6 ohms for measuring the potential drop across the resistances R_1 and R_2 in Fig. 1. Since the maximum voltage is measured through the current in R_1 or R_2, it is obviously of the first importance that the galvanometer be accurately calibrated. The calibration directly in amperes was effected by passing continuous current through R_1 or R_2 and measuring this current through the resulting potential drop over a resistance of 499 ohms always in this auxiliary circuit; the potential drop was measured on a precision potentiometer in terms of a Weston cell. The value of the resistance was determined to within 1/25 of 1 per cent by comparison with certified laboratory standards. Two certified Weston cells were used, one checking the constancy of that in use with the potentiometer; at the end of the observations their values were equal to the fourth decimal.

The galvanometer was calibrated for every series of observations and usually at approximately the scale reading pertaining to the particular charging current being measured; see Table VII.

In order to investigate a possible error due to the pulsating character of the galvanometer current when the instrument is calibrated for continuous current, an extensive series of observations was made using the commutator for breaking up continuous current and for cutting out alternate half waves of alternating current. These experiments have been described in another paper,[10] and show that when the galvanometer

is connected as in Fig. 1 or Fig. 3 the calibration with continuous current is accurately the same as that with pulsating current whether rectangular or of approximately sine shape.

(e) *Resistance of Ground Connection.* Since the central section of the air condenser is connected to ground through the resistance and kenotron circuits of Fig. 1, two questions arise as to the effect of the resistance of these circuits on the charging current of the condenser. First, if the resistance of this circuit is sufficiently high the voltage across the terminals of the condenser may be appreciably lower than the total voltage between high-tension terminal and ground; and second, if the resistance in question is sufficiently high, suitable adjustment must be made to ensure equal potential between the central section of the condenser and the guard rings, or otherwise the current in the kenotron circuit would not be that due to the capacity between the high-voltage member of the condenser and the central section of the grounded member alone.

With reference to the first of these questions, the calculated capacity of the central member of the condenser is 8.262×10^{-11} farads. The measured value is 8.286×10^{-11} farads, (see paragraph (h) below). The corresponding reactance at 60 cycles is therefore 3.2×10^7 ohms. The resistances R_1 and R_2, Fig. 1, were 2000 ohms each throughout the experiments. The equivalent resistance of one kenotron varies with its filament current and also with the current that the kenotron is transmitting. The values of these resistances were determined by taking the volt-ampere characteristics of the kenotrons with continuous currents. It is not thought necessary to reproduce these readings here, as the characteristics of the kenotron are well-known. The maximum value of kenotron resistance obtaining in the experiments was approximatley 4000 ohms.

The filament currents of the two kenotrons were always adjusted to the same value as indicated by a direct-reading continuous-current instrument. Slight variations in the filament current have no effect on the transmitting power of the kenotron and only produce small variations in the equivalent resistance of the kenotron.

Consequently the maximum aggregate resistance in the ground circuit of the central section at any time was approximately 6000 ohms. This noninductive resistance is in series with the capacity reactance of 3.21×10^7 ohms of the central section of the condenser and has therefore a quite negligible effect either in elevating the potential of the outer member of the condenser above ground, or in reducing the voltage at the condenser terminal below the full applied value.

The accuracy of the above deductions was tested by connecting the central section of the condenser to ground through resistance only and similarly the two guard rings in parallel to ground through resistance only. The voltage drop over these resistances was studied by means of the commutator and galvanometer. The results showed that the voltage drop over each resistance was accurately proportional to its value. They also showed that the values so measured on either resistance were independent of the value of the other resistance within the range 0 to 10,000 ohms, the study not being carried further.

With reference to the second question raised above, namely, as to the effect of a difference of potential between the guard rings and the central section on the values of the charging current to ground from the central section, it would appear from the foregoing that, since the difference of potential between the two members is negligibly small, and furthermore since the capacity between them is also small, no influence on the charging current of the central section would be found even if the guard rings were connected directly to ground. However, it was thought best to investigate the matter experimentally and also to determine the proper value of resistance to connect between the guard rings and ground in order to ensure that the guard rings are at the same potential as the central member. The results of this study are given in Table III.

Referring to Table III and Fig. 1, the first column gives the value of the resistance R_3 between guard

$R_1 = R_2 = 2000$ ohms. Filament current 2.75 amperes.

rings and ground; the next three columns right, left and mean readings of the galvanometer connected between D and F of Fig. 1 using the commutator for rectification; the next three columns voltage over R_2; and the next three that over R_1 both without use of commutator; and the last three columns the voltage over R_3 with the aid of the commutator. These results show that the voltage between the point D and ground and the voltages over the resistances R_1 and R_2 are all independent of the value of the resistance R_3 up to 10,000 ohms. Furthermore they show that the guard rings are brought to the same potential as the central section when connected to ground through a resistance R_3 of 5,970 ohms. R_3 was kept at this value throughout the course of the work.

(*f*) *Measurement of Frequency.* The value of frequency enters directly from Formula (**4**) into the expression for the maximum value of voltage. Constancy of frequency therefore and as accurate a determination of

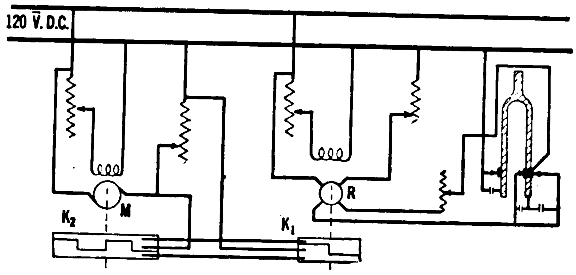

FIG. 6—CONTROL OF FREQUENCY BY TUNING FORK

its value as possible are highly essential to an accurate determination of the maximum voltage.

As regards constancy, the 5-kw. single-phase generator was driven by a continuous-current motor run as the only load on a large storage battery. This constant source of supply was further supplemented by an automatic speed control illustrated in Fig. 6. In this method the ultimate source of constant speed is an electrically operated tuning fork. A small rotary converter, R, of the same frequency as the tuning fork is driven from the direct-current end and is loaded with a resistance on the alternating-current end, the load circuit being taken through a pair of contacts on the tuning fork, contact being made once during each half wave. The time interval of contact by the tuning fork is a fraction of the whole alternating-current period. If the speed rises, contact is made at an instant when there is a greater electromotive force and current, thus resulting in a greater load on the converter. If the speed goes down, the conditions are reversed, consequently the tendency of the change of load is to maintain the speed of the converter constant. This tendency can be made greater or more positive by inserting resistance in the armature circuit of the continuous-current end of the converter.

The shaft of the small converter and that of the larger machine which is to be controlled are each supplied with a crown commutator, K_1 and K_2. The number of commutator segments for each is chosen so that by their speeds the frequencies of reversal of the two commutators are the same. The commutators are connected together electrically, as indicated in Fig. 6, in such a way as to short-circuit a small resistance in the armature circuit of the main driving motor for a greater or less period, according as the commutators depart more or less from the position of exact coincidence of phase. The machines automatically find such a relative commutator phase relation that an increase in speed decreases the duration of short circuit of the armature resistance, and vice versa, so that the average voltage on the motor armature is such as to more or less exactly maintain the speed in a constant relation to that in the small converter, which in its turn is maintained constant by the tuning fork. The introduction of the small converter is necessary, since the tuning fork contacts will not carry the large currents interrupted in the control of the considerably larger direct-current motor.

The use of the foregoing method prevented slow changes of speed due to temperature changes in the motor, or to variations of applied voltage, etc. Occasionally changes of this character were sufficiently great to overcome the regulating power of the tuning fork and the resulting upset in frequency was immediately indicated by the "beats" between the two frequencies detected by means of a pair of stroboscopic disks, one on each machine and through either of which the tuning fork might be viewed. In this way it was possible to tell at any instant by a glance whether the frequency was constant.

Observations taken with the stroboscopic disks indicate that by the above method the frequency was maintained constant at within 0.5 per cent. In this connection it is to be noted, however, that as read by the galvanometer, the charging current of the air condenser is read as an average value. Consequently, so long as the frequency is kept to an average constant value, momentary changes of frequency will not be registered in the galvanometer. This was borne out by the general character of the galvanometer reading, this reading being always absolutely stationary and not subject to any momentary variations which could be detected.

(*g*) *Value of Frequency.* Most of the measurements described in this paper were made at 60 cycles and this frequency is to be understood unless particular note is made of some other value. The frequency of the tuning fork was measured each day by bringing the small rotary converter into synchronism with the fork by the method described above and then taking the speed of the rotary by means of a "tachascope" or, combined revolution counter and stop watch. The speed of the rotary corresponding to 60 cycles for the alternating generator was 1800 rev. per min. The usual method of observation was to take the number of revolutions of the rotary within a period of three min-

utes, taking this observation three times and taking the mean of these for the determination of frequency. Table IV gives an example of the measurements which indicate that the average frequency was determined to within 0.04 per cent.

(*h*) *Capacity of Air Condenser*. As already stated, the air condenser was of concentric cylinder type. It had a continuous inside member and an outer member

consisting of a central section protected at each end with guard rings. A photograph is shown in Fig. 7. Both members were made from standard cast iron pipe. The surface of the inner member was turned off so as to have a uniform diameter and to be free from surface

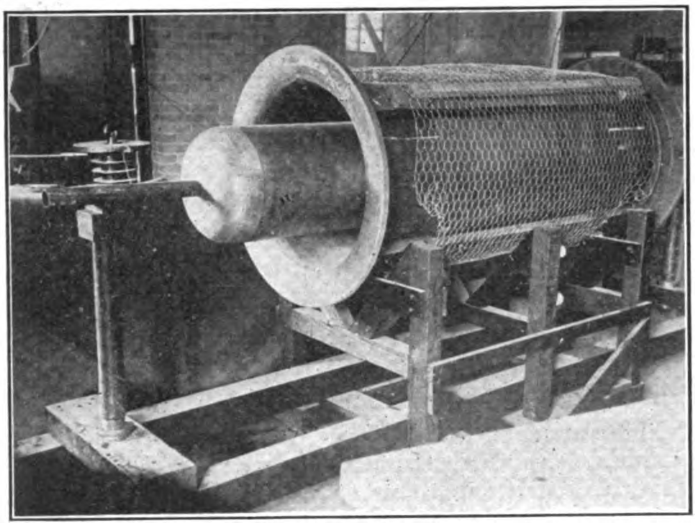

FIG. 7—AIR CONDENSER

irregularities. The ends were filled with rounded wooden plugs covered with tin foil and the whole inner member was supported by a 1½ in. pipe through central holes in these wooden plugs. The guard ring ends of the outer member consisted of straight sections on the outer ends of which were mounted standard flanges screwed on, the inside surfaces being turned off so as to provide a smooth flaring end to each guard ring.

The central or inner member was supported on dry oak posts boiled in paraffin. Sliding and screw adjustments at the top and bottom of these posts permitted accurate centering in relation to the outer member. The two guard ring ends were tied together by means of four stout oak pieces maintaining them in line. The central section of the outer member was supported on eight small plate glass insulators mounted in the four oak pieces mentioned. The whole was then supported in a wooden cradle, as indicated in Fig. 7.

Following are the principal dimensions of the air condenser:

Diameter of inner member......29.50 cm. (11.61 in.)
Average diameter of outer member..........................49.30 cm. (19.42 in.)
Length of central section of outer member....................76.20 cm. (30.00 in.)
Length of guard ring ends......30.5 cm. (12.00 in.)

The inside diameter of the outer member was not strictly uniform. It was measured in twelve places, the extreme variation being between 49.20 cm. and 49.51 cm. The calculated value of the capacity between the central section of the outer member and the inner member, based on the average diameter of the outer member given above, is 8.249×10^{-11} farads. In view of the uncertainty introduced by slight irregularities of this character, it was decided to measure the capacity.

The measurement of so small a value of capacity is a matter of considerable difficulty and requires much care. Maxwell's bridge method was used, following in general the experimental method of Rosa and Dorsey[11]. We were fortunate in being able to borrow

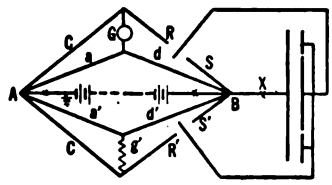

FIG. 8—MEASUREMENT OF CAPACITY OF AIR CONDENSER (8.28×10^{-11} FARADS)

from the National Bureau of Standards the special commutator constructed by them.

The diagram of the connections of this method is shown in Fig. 8. The principle is well-known and consists in replacing one of the resistances in a Wheatstone bridge with a condenser, and a suitable device for rapidly charging and discharging the condenser. In the arrangement shown in Fig. 8 the charging current only is used, the condenser being short-circuited in the alternate intervals. If, as in our case, the condenser has guard rings, it is necessary that they follow the same cycle of potential as the central section to be measured. This is accomplished by the double bridge shown in Fig. 8. R S and R' S' are contacts carried on the special form of rotating commutator constructed by Rosa and Dorsey for effecting the simultaneous charge and discharge of the central and guard ring members.

The bridge is balanced by varying the arms a and a' and when in proper adjustment corresponding arms in the two bridges must have identical values. The

value of the capacity between the inner member and the central section of the outer member is

$$C = \frac{a\,F}{n\,c\,d} \tag{5}$$

a, c and d are values of resistance; n is the number of charges of the condenser per second; and F is a correction factor depending on the relative values of the resistances, and differing but little from unity; in our work by about 3 points in 100,000.

The values used by us were as follows:

$$c = c' = 521{,}000 \text{ ohms}$$
$$d = d' = 50{,}000 \text{ ohms}$$
$$g = g' = 1{,}124 \text{ ohms}$$

The high resistances were of manganin made up of specially wound non-inductive units lent by the Bureau of Standards. The remaining resistances were of standard, high-grade, laboratory type, and all values as given were measured in terms of laboratory standards to 0.04 per cent.

For the determination of n, the number of charges per second, the commutator which had sixteen segments was geared directly to the small rotary converter controlled by a tuning fork by the method of Fig. 6, as already described. Two speeds differing by the factor 2 were possible with this arrangement, control of the machine speed by the fork being effective at either speed. Moreover, observation by means of the stroboscopic disk as to the constancy of the speed was also possible. The fork thus served for maintaining the frequency of charge and discharge at the average uniform value pertaining to either of two speeds. The value of this frequency, and thereby the value of n, was determined by a contact-making device on the commutator and a stop watch. The normal speed of the rotary was 1800 rev. per min. and this corresponded to the value of $n = 480$. The accuracy of the speed determination and so of the value of n was therefore within 0.04 per cent.

In measuring the capacity it was necessary to make a correction due to the capacity of the lead wires between the condenser and the bridge. This was done by measuring the capacity first with the condenser in and then with the connection to the central member of the condenser opened at the point X, Fig. 8. Two precautions have to be taken following this method; first, as to the insulation resistance of the capacity to be measured and the insulation resistance of the central section of the outer member to ground; and second, the capacity between the bridge wiring and the central member when the connection at X is opened.

With reference to the insulation resistances mentioned, it was found that in moist weather the values were relatively low, say of the order a few hundred megohms, doubtless owing to the rather large surfaces of support of the heavy parts. However, in clear dry weather the resistances were greater than one-half million megohms, a figure which reduces the possible error on this account to quite negligible proportions. These figures include the commutator insulation and were checked at each series of observations for the measurement of the capacity.

As to the possible error due to a charging current from the open contact at X through the capacity to the central member and thence to the outer member, this error was avoided by completely enclosing the projecting ends of the central member of the condenser by means of large cones made of galvanized sheet iron, the connection to the central member being carried through a small opening in one of the cone ends. The opening X was made at this place and under these circumstances the interior central member was entirely screened during the measurement for the correction due to the capacity of all the auxiliary wiring.

The most difficult part of this measurement is the adjustment of the brushes on the commutator for simultaneous charge and discharge of the central section and the guard ring ends. This requires very careful study of the conditions of contact of the brushes on the commutator sections, so as to prevent mechanical vibration and to ensure a reasonable permanence

of a proper adjustment when once it is effected. Probably the best test of these conditions is by means of an auxiliary circuit through the brush contacts, indicating by means of a galvanometer the ratio of the running to the standstill deflections. By taking the two sets of brushes in turn singly and then in series, a quite accurate idea of the conditions is obtainable. Throughout the measurements of capacity, observations of this character were taken both before and after the capacity readings, thus ensuring satisfactory conditions. As an additional precaution in this direction a double set of readings was always taken, the duplicate contacts of the commutator being exchanged for the two readings between the central section of the condenser and the guard rings. Table V gives the readings which were selected as having been taken under the most favorable conditions, that is to say, those in which there was least difference between the two values of capacity corresponding to the exchange of the two sets of brush contacts.

The figures given in Table V are the values of the resistance "*a*" in ohms. The words "right and "left" refer to the particular set of commutator brushes used. It will be noted also that readings were taken for two speeds and for each speed a reading for a reversal of the polarity of the battery of the bridge. The value of the capacity in each case is calculated by means of Formula (**5**). The final average value of these readings is 8.286×10^{-11} farads. The calculated values based on independent measurements of the dimensions by each of the authors were 8.28×10^{-11} and 8.245×10^{-11} farads.

In computing the maximum value of voltage the measured value of the capacity, 8.286×10^{-11}, has been used.

(*i*) *Electrostatic Screening.* In view of the small value of the current to be measured, especial care had to be taken for the elimination of all electrostatic inductive effects between the high-tension circuit, the outer surface of the condenser, and the various measuring circuits in the ground connection of the condenser. With the sensitive galvanometer used it was found that the unscreened exposure of relatively small and distant portions of the wiring could introduce considerable error. It was necessary for the elimination of errors of this character to completely enclose in grounded casing all of the low-voltage measuring circuits of Fig. 1, including the various auxiliary circuits not shown; thus the kenotrons, the resistances, R_1, R_2 and R_3 and their various control circuits were enclosed in one sheet-iron box. The entire equipment of the observer's station, including the galvanometers for the measurement of the charging current and for the detection of corona and the various calibrating circuits were all enclosed in a small chamber completely surrounded with wire mesh. The condenser itself was surrounded with an outer screen of wire mesh. All connections between these various parts were likewise carried in metal conduit. All of the screening coverings described were connected together and to ground.

The test for completeness of electrostatic screening consisted in opening the high-voltage connection to the

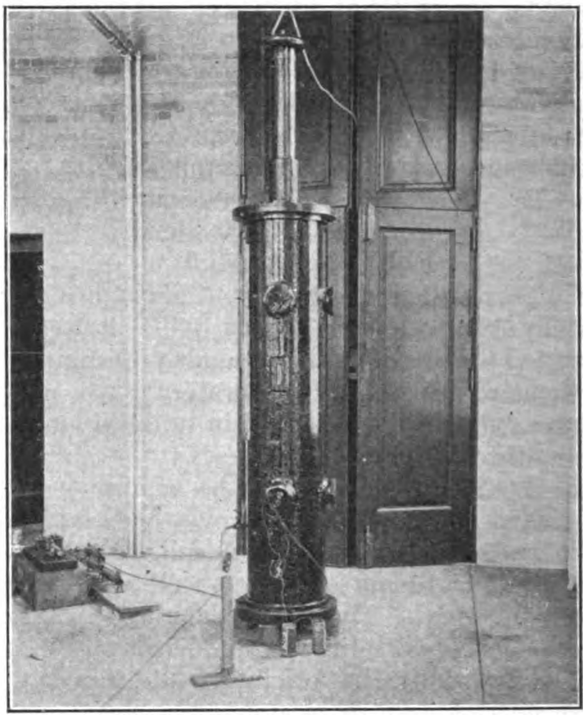

Fig. 9—Corona Voltmeter—200,000 Volts

central member of the air condenser at P, Fig. 3, applying the voltage, and observing the galvanometer in the method of connection of Fig. 3. In this observation the value of R_1 was 9900 ohms and is about five times the value used in the charging current measurements. The sensitivity of the galvanometer used was

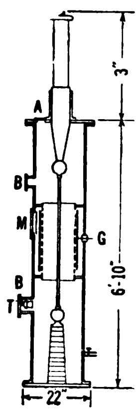

Fig. 10—Corona Voltmeter—200,000 Volts

1250 megohms and no deflection could be detected. The galvanometer could be read to 0.2 millimeter which, in accordance with the magnitude of the deflections corresponding to the charging currents measured, means that an error on account of electrostatic induction, if present, is less than 0.1 or 0.2 per cent.

III. 2. Detection of Corona

All of the corona observations on which the measurements are based were taken with the corona voltmeter shown in Fig. 9. A vertical section (not to scale) is shown in Fig. 10. The principal dimensions are,—height overall 9 ft. 10 in.; outside diameter 22 in.; diameter of grounded electrode cylinder 24.67 cm. (9.715 in.); length 60.95 cm. (24 in.). This cylinder was perforated over its whole surface with 0.952-cm. (0.375-in.) diameter holes on 1.27-cm. (0.5-in.) centers. The corona rods, 11 in number, of diameters ranging from 0.1038 to 1.2665 cm. were of tool steel polished and nickel-plated, and were all of the same length and equipped with similar threaded end fittings. A small opening A in the top cover permits easy insertion or removal of a rod, attachment of fittings to top and bottom insulators being made through two hand holes in the sides (see A, B, B, Fig. 10). These openings are closed with air-tight covers. The cover at A has a glass window permitting observation of visual corona. The locations of the thermometer M, the telephone, the connections T and G for telephone and galvanometer, and other auxiliaries are indicated in Fig. 10.

(*a*) *Visual Corona.* Attention was first drawn to the phenomenon of the high-voltage corona by the power loss between transmission lines. This was promptly found to be accompanied by the visual corona around the conductors. All of the early studies of corona formation, of which the most notable were those of Ryan, gaged the first presence of corona by visual means. The visual method, however, is neither convenient nor accurate. It necessitates working in a dark room and is subject to error, in that accurate observation depends upon the state of the eye as regards its recent usage, fatigue, etc.

Nevertheless, under carefully controlled conditions using long time intervals for eye rests, it is possible to secure consistent observations with the visual corona. In the earlier papers of one of the authors comparisons of corona voltages as between the visual and other methods have been recorded showing that they have identical values. In the present work observations of this character have been repeated in some of the auxiliary experiments and they show the identity of corona voltages as observed by the visual method and by the far more convenient and accurate galvanometer. The visual method has, however, not been used for the measurements, the telephone and galvanometer being far more accurate and convenient.

(*b*) *The Telephone as Detector.* The presence of corona may be detected by its sound even in an open space. If the corona conductor is surrounded by an outer casing, such as a cylinder forming the opposite conductor, the sound within this enclosing space is confined and intensified. It may be conveniently used as a detector of the first presence of corona by means either of a direct tube connection between the ear and the enclosing chamber, or by means of a telephone transmitter within the enclosing chamber and a receiver at the ear. The latter method is necessary if the air pressure is to be varied and so is used in the corona voltmeter.

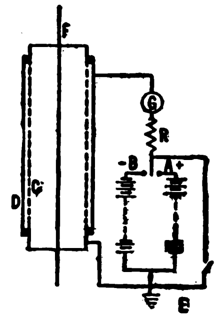

Fig. 11—The Galvanometer as Detector of Corona

A number of experiments have been recorded in earlier papers, showing the identical values of corona voltages as observed visually, with the telephone, and with the galvanometer method described below. During all of the present work the telephone and galvanometer have been used simultaneously and the work throughout makes it certain that either of these methods may be used for detecting the first presence of corona.

*Telephone.

The present work, however, has revealed that the character of the note in the telephone is different under different conditions as regards the size of the corona conductor and the density of the air surrounding it. This feature has considerable value after slight experience in the operation of the corona voltmeter, as it gives the observer information as to the conditions under which he is working. As regards its bearing on the accuracy of the telephone as a method of telling

the first presence of corona, it is only necessary to note that the first uniform continuous note, whether it be faint and high or considerably louder and of lower tone, is to be taken as the signal of the presence of corona. The first type mentioned pertains to large wires at low pressure and the second to smaller wires and higher pressures.

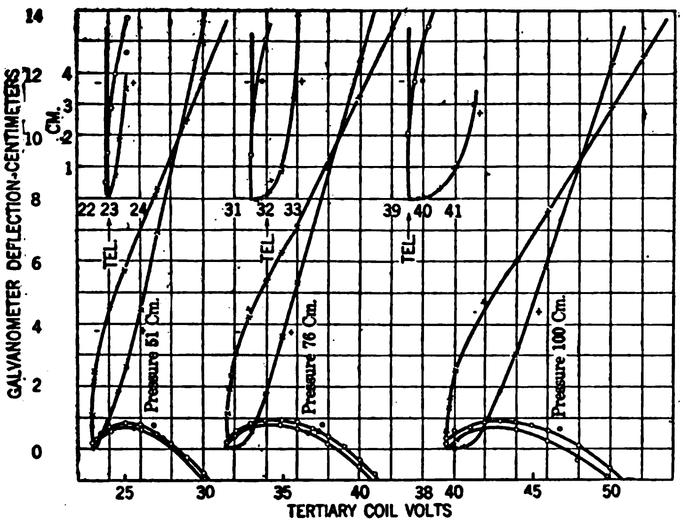

Fig. 12—Galvanometer as Detector of Corona—0.314-Cm. Diam. Rod

Irregularities or other surface imperfections of the corona rod can usually be detected in the telephone by a characteristic crackling note quite distinct from that of corona.

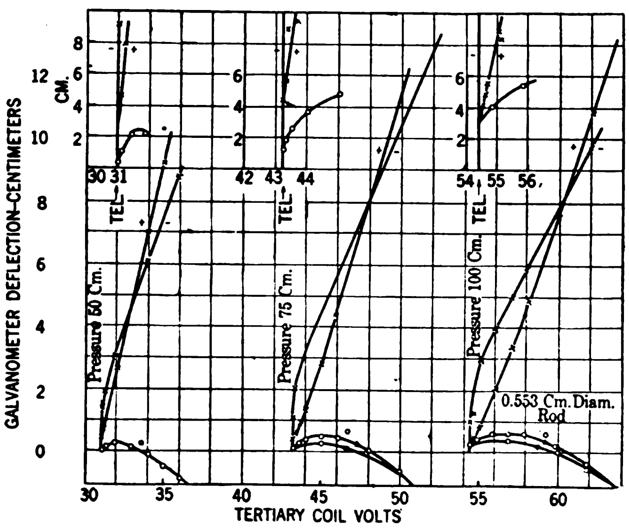

Fig. 13—Galvanometer as Detector of Corona—0.553-Cm. Diam. Rod

(c) *The Galvanometer as Detector.* The essential elements of the galvanometer method of detecting corona are shown in Fig. 11, in which C is the perforated cylinder in the corona voltmeter which is connected to ground and to one side of the voltage to be measured; D is a surrounding cylinder only slightly larger in diameter than C, from which it is carefully insulated. The remaining elements of the circuit are obvious from Figs. 1 and 10. When corona appears on the central rod F, the surrounding air is copiously ionized and this ionization extends through the perforations to the space between the cylinders C and D which thus becomes highly conducting, resulting in a deflection of the galvanometer G.

An extensive series of observations has been made with corona rods of various size and under different conditions as to temperature and pressure on the relation between the voltage on the corona rod F and the resulting galvanometer deflections. A characteristic series of observations are given in Table VI, and the corresponding curves are plotted in Figs. 12, 13 and 14. In connection with these observations it may be noted that the sensitivity of the undamped galvanometer was 1280 megohms, and when critically damped with a shunt of 3400 ohms the sensitivity

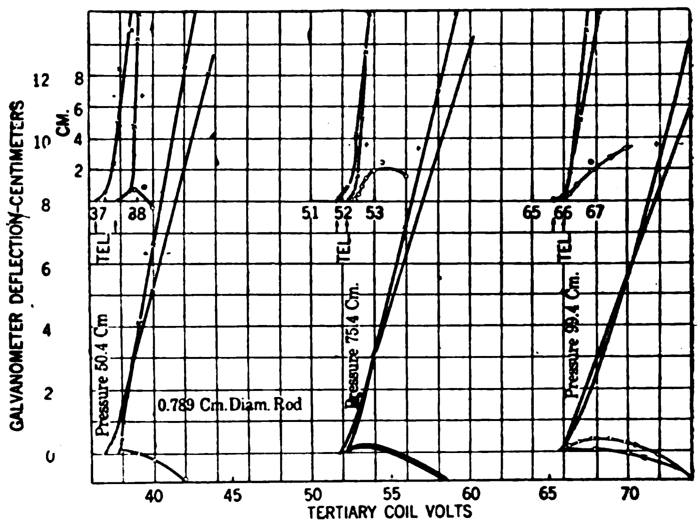

Fig. 14—Galvanometer as Detector of Corona—0.789-Cm. Diam. Rod

was 428 megohms. The resistance R was 50,000 ohms and the battery $\pm$ 115 volts. From the dimensions of the corona voltmeter already given, the length of the cylinder D was 60.95 cm., its diameter 24.67 cm., and its space separation from the cylinder C 0.317 cm. From these constants and from the observations the resistance of the space between C and D when in the initial conducting condition corresponding to the start of corona is about 1600 megohms.

Figs. 12, 13 and 14, pertaining to three different sizes of corona rod, are plotted with galvanometer deflections in centimeters as ordinates and transformer tertiary coil volts as abscissas. Each contains three sets of curves taken at different values of air density. The upper smaller curves are taken with the value of galvanometer sensitivity used throughout the voltage measurements. The larger curves are taken with galvanometer sensitivity reduced to 1/10 in order to extend the curves. Three curves were taken at each pressure, one each for the electrode D

of Fig. 11 at 115 volts positive potential, one at 115 volts negative potential, and one at ground potential. The value of voltage at which the telephone is first heard is also indicated. It is to be noted that in all of these curves negative potential on the electrode D is best for the detection of the first presence of corona in that the curve rises most sharply. This is especially noticeable with small rods. With larger rods the advantage of negative over positive potential holds at low pressure, but tends to disappear at high pressures.

With larger rods at low pressures where the negative electrode should be used for first detection of corona, the telephone gives a pure high note of relatively faint volume within the interval of voltage between the curves of negative and positive electrodes, the full volume of sound appearing when the latter curve begins. At high pressures the curves come together; and with either positive or negative electrode the first corona is accompanied by a full sound in the telephone. With the smaller rods, although there is also a lag of the rise of the curve of positive electrode behind that of negative electrode, the faint initial high tone in the telephone is absent and except at very low pressures there is no marked variation in the telephone note, this note being clear and full with the first appearance of corona with negative electrode.

Considering the foregoing, therefore, from the standpoint of accuracy of determination of the first appearance of corona, negative potential should be used on the electrode D in all cases. Conditions of observation with both telephone and galvanometer are better at values of air density above that of normal atmosphere, rather than below, if large rods are used. Consequently, for reading low voltages better conditions are obtained by using a small rod rather than by using a large rod with reduced air density.

The difference in shape of the curves of positive and negative electrode has been noted in an earlier paper. The greater sensitivity of the negative electrode is obviously due to the fact that corona formation or ionization of the air occurs first due to the motion of the negative electrons. The acceleration of the electron is greatest when it is moving toward the positively charged corona conductor. Under these circumstances the positive ions, as products of the process of ionization, would be repelled and would therefore give maximum current in the galvanometer circuit of Fig. 11 when the electrode D is negative. The exact shape of the curves probably depends on the wave form of voltage, moisture content of the air, and possibly on the frequency. It is only the initial slope of the most sensitive of these curves that is of importance in the detection of corona; their shape above the region of starting is of no present interest. It may be noted in passing, however, that it is possible to eliminate the voltage for the electrode D entirely and still observe the beginning of corona, although at a considerably lessened sensitivity. The curves showing the galvanometer deflection when the electrode D is at ground potential are seen to show reversal of galvanometer deflection at the voltage at which the curves of positive and negative electrodes intersect.

With reference to the actual degree of accuracy to which the beginning of corona could be observed, it will be noted from Fig. 12 that the galvanometer deflection begins and increases so sharply as to be practically instantaneous. Thus, for example, in Table VI and Fig. 12 the galvanometer deflection increases from 0 to 11.7 cm. within the voltage interval 31.4 to 31.5, the telephone coming in sharply at the same point. This indicates an accuracy of a very small fraction of 1 per cent. With the larger rod in Fig. 14 at high pressure we have a deflection of 1.4 cm. within the voltage interval 65.9 to 66. At low pressures the deflection is 2.4 cm. within the voltage interval 36.7 to 37.2. From this it will be seen that the sensitivity of corona detection is still quite high even under the unfavorable conditions of large rod at low pressure.

Throughout the observations the telephone and the galvanometer were read simultaneously, each checking the other. If an appreciable galvanometer deflection occurred without a corresponding clear telephone indication, or vice versa, an explanation could usually be found in a local spark or other surface impurity on the rod. We believe, in view of the foregoing that throughout the work the accuracy with which the beginning of corona has been read is better than 1/10 of 1 per cent. In this connection it may be pointed out that the initial flat portion or low rate of rise of the negative curves with large wires can only be detected by use of a very sensitive instrument. These initial portions are probably due to slight surface imperfections rather than to full corona. This is borne out by the fact that the full telephone note comes out at a point corresponding to the steep portion of the curve. With an instrument of lower sensitivity, such as would normally be used with the corona voltmeter, these initial portions of the curve cannot be detected and the instrument takes an initial sharp deflection accompanied by the simultaneous telephone note.

III. 3 Measurement of Air Density

The relative air density δ as given in Formula (3) is

$$\delta = \frac{3.92 \times p}{273 + t} \qquad (3)$$

p being the absolute pressure in centimeters of mercury, and t the temperature in degrees centigrade. Thus δ has the value 1 at 76 cm. mercury and 25 deg. centigrade.

(*a*) *Pressure.* In the experiments the pressure was read on an open mercury manometer, (see Fig. 10), the accuracy of observation therefore being to about 0.2

millimeter. The usual correction for temperature was applied. All of the observations leading to the precision Formulas (7) and (8) for the electric strength of air were taken within the range of pressures 25 cm. and 139 cm. absolute, all of which was covered by the mercury manometer. A number of observations studying the performance of the corona voltmeter at higher pressures were made with a standard direct-reading gage by Schaeffer & Budenberg, calibrated within their common range in terms of the mercury manometer.

At the highest and the lowest pressures slight leaks in the outer casing of the voltmeter were detected. These leaks were, however, quite slow and pressure readings were taken at the beginning and end of each series of voltage readings. The average value of pressure within the interval was usually taken in these cases and an inspection of Table VII indicates that the error on this account was negligible. In calculating δ, p is the absolute pressure in centimeters of mercury. The open mercury manometer reads pressure with relation to the atmosphere. Atmospheric pressure was determined from the laboratory standard barometer with the usual correction for temperature.

(*b*) *Temperature.* The temperature within the volt-

meter casing was read on an ordinary laboratory centigrade thermometer hung within the casing near its wall and so that it could be viewed through a small glass window. The thermometer could be read to within about 0.2 degree. From an inspection of the value of δ this indicates that the absolute temperature was read to within less than 1/10 per cent.

The determination of the temperature in this way assumes that the temperature of the air at the surafce of the corona rod is the same as that near the outer wall of the voltmeter. There is an obvious possibility of error here, so the matter was investigated experimentally by comparing the thermometer mentioned above with another hung immediately adjacent to the corona rod and viewed by telescope through another glass window. The curves of Fig. 15 show the difference in temperature between these two thermometers resulting from rapid expansion and compression of the air within the voltmeter. They indicate that on compression from atmosphere to 30 cm. above atmosphere there is a resulting difference of temperature of about 1 deg. and on expansion of approximately ½ deg. between the two thermometers. In the former case the two thermometers reached the same temperature within five or six minutes and within a shorter interval in the latter case. In the observations no such sharp changes of pressure occurred, the common maximum change being about 10 cm. In all cases, however, sufficient time was allowed to ensure that the observed temperature was sensibly the same as that near the corona rod.

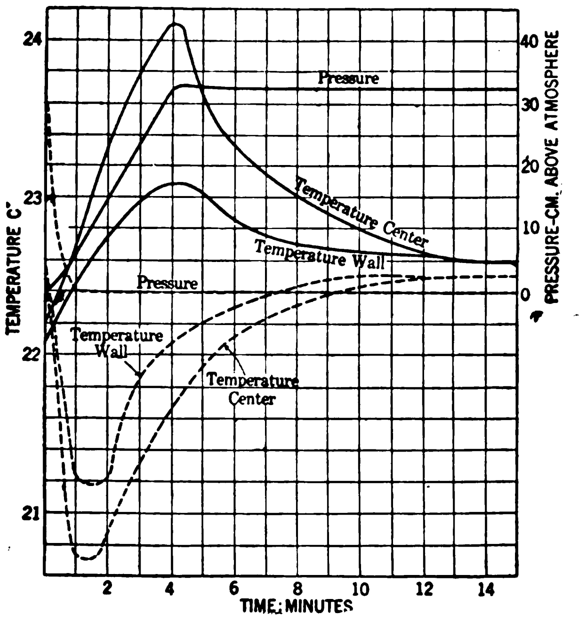

Fig. 15—Temperature at Surface of Corona Rod

IV. Experimental Observations

Many hundreds of observations were taken with eleven different sizes of corona rod of diameters as follows: 1.266, 0.955, 0.790, 0.710, 0.654, 0.5536, 0.4765, 0.3142, 0.2060, 0.1197, 0.1038 cm. The figures for the diameters given in the tables and computations are the average values taken from 20 micrometer measurements on each rod. Except in the cases of the smallest rods, the maximum variations from the mean diameters as given were quite small, that is, in the neighborhood of 0.2 or 0.3 per cent. The rods were all of tool steel and nickel-plated after polishing, this material and treatment yielding the most accurate cylindrical shape and smoothest surface that we have found. The extremes of absolute pressure reached in the precision determinations were 25 cm. and 139 cm. of mercury, although not all the rods were carried through the entire range.

The usual sequence in taking observations was as follows: Adjust frequency control and read its value; set pressure in corona voltmeter to desired value; adjust filament current and kenotron circuit for zero current in the closed kenotron circuit; read temperature and pressure in voltmeter; raise voltage slowly until corona begins, as indicated by galvanometer and telephone; read value of charging current of condenser by galvanometer.

One observer took the temperature and pressure and read the charging current galvanometer. A second observer, who raised the voltage, was equipped with telephone head-piece and read the galvanometer indicating the beginning of corona. This observer also took a reading of an ordinary direct-reading voltmeter connected to the tertiary coil of the high-tension transformer. This last reading was useful as a check of the constancy of circuit conditions and for rough comparisons, but its readings were not used in any computations. At the instant that the presence of corona was detected by galvanometer and telephone the slow elevation of voltage would be stopped and the first observer would take the reading of the charging current galvanometer. Obviously the voltage elevation could be made as slow as desired and frequent check readings were taken which do not appear in the record. The degree of constancy of the corona voltage is discussed in the following paragraph. After each series of observations the charging current galvanometer was calibrated at a deflection approximately equal to that of the observation.

Table VII gives six typical sets of readings of the principal data, these sets being selected at random from the observation sheets. The first six columns give the frequency, temperature and pressure, leading to the corrected absolute pressure in Column 6. Columns 7 and 8 give the right and left readings of the galvanometer measuring the condenser charging current. It will be noted that there are four pairs of such readings for each value of pressure. Between the readings of each pair and between each of the pairs the voltage was lowered below corona value and raised again. The readings of these columns therefore are a good indication as to the accuracy with which corona formation repeats itself.

Since the beginning of corona is indicated by the telephone and by a sudden sharp deflection of the galvanometer rather than by the magnitude of the deflection of the latter, this latter reading was not recorded. (See however Figs. 12, 13 and 14.) A direct relative indication of the alternating voltages at which successive coronas start is available, however, in the tertiary coil voltmeter and the readings of this instrument are given in the last column of Table VII.

Referring to the readings of the pressure, it will be noted that there is usually a difference in the net readings of the mercury manometer at the beginning and at the end of each series of four pairs of corona readings. These differences are due to slight leakage of the voltmeter casing and are therefore greatest for the highest and lowest absolute pressures. The differences are never very great and when they occur they are followed by a corresponding change in the corona voltage as indicated by the condenser charging current. Therefore in taking for each set of readings the average value of the pressure and the average value of the galvanometer reading no appreciable error is introduced.

Three sets of auxiliary observations should be recorded here bearing, respectively, on the perforation of the grounded cylinder, the influence of frequency and the permanence of the surface of the corona forming rod.

As regards the holes in the grounded cylinder, a number of observations from time to time have shown that these perforations have no effect on the value of the corona-forming voltage; for example, in the paper "The Electric Strength of Air.—III"[13] a number of experiments were conducted with an outer cylinder made of wire mesh of a quite wide opening. The values of corona voltage observed in this case were sensibly the same as those obtained with cylinders with continuous walls. Further, numerous readings taken with outer cylinders having continuous walls have shown that the voltages at which visual corona appears are in accord with those observed in the corona voltmeter. In order, however, to make a direct test of this question, two series of observations of visual corona voltage were taken, using in the two cases outer cylinders cut from the same length of brass tubing, one piece being perforated and the other not perforated.

The two tubes were each 9.5-cm. inside diameter and of length 24 cm. One was perforated with 0.27-cm. diameter holes drilled as closely as possible to each other and in a number of cases being actually tangent to each other. A clean rod 0.315 cm. in diameter was centered in each of these tubes in turn and visual corona observations taken with a rested eye in a darkened room. The corona voltages as measured on the transformer tertiary coil in the two cases were: with perforated cylinder 23.5, 23.4, 23.4; with unperforated cylinder 23.4, 23.5, 23.6, 23.5, 23.5. There appears therefore no reason to question that the perforations in the grounded cylinder have no effect on the value of corona-forming voltage.

As regards the influence of frequency on corona-forming voltage, in the paper "The Electric Strength of Air.—II",[14] experiments were described which indicated a slight lowering of corona voltage with increasing frequency between the range 10 and 100 cycles. Subsequently Whitehead and Gorton[8] have extended the range of frequency up to 3000 cycles and have shown that within the range 500 to 3000 cycles there is practically no influence of the frequency on the corona-forming voltage. They noted, however, that the value of corona voltage within this range was from 3 to 4 per cent lower than at 60 cycles. F. W. Peek records that within the range of commercial values the frequency has no influence on corona-forming voltage.

TABLE VIII.
INFLUENCE OF FREQUENCY.

Frequency cycles per second	Values of $\frac{E}{\delta}$ at $\frac{1}{\sqrt{\delta r}} = 2.03$	Aver.
20	50.41, 50.50	50.45
40	50.25, 50.25, 50.39, 50.5	50.35
60	49.95, 50.07, 50.13	50.05
90	49.24	49.24

Having at hand the accurate method of measurement already described, a series of observations was taken on the influence of frequency between the values 20 and 90 cycles. The readings were taken on a rod 0.48 cm. in diameter and at atmospheric pressure. Several readings at each frequency were taken and all were reduced to the same value of $\frac{1}{\sqrt{\delta r}}$. The corresponding values of E/δ are given in Table VIII.

The above figures indicate that there is a small influence of frequency on corona-forming voltage within the range 20 to 90 cycles. For example, the corona-forming voltage at 25 cycles is shown to be about 0.8 per cent higher than at 60 cycles. All of the other observations of this paper were taken at 60 cycles and therefore the laws of corona formation, as discussed below, pertain to that frequency.

As regards the permanence of the surface of the corona-forming rod, experiments have shown that a practically indefinite number of corona observations may be taken without deterioration of the surface of the nickel-plated steel rods used. These experiments consisted in maintaining corona on a rod for a long period of time, interrupting it at regular intervals and taking the corona-forming voltage. One of several such tests consisted in maintaining a 0.476-cm. diam. rod at a voltage 2.5 per cent above the corona-forming

value for one hour, and taking the corona-forming voltage six times during the interval. At start the corona-forming voltage as indicated at the tertiary coil terminals was 40.1; at successive intervals through the hour the values were 40.05, 40.05, 40.05, 40.15, 40.2, 40.1.

If the voltage is carried higher, increasing the volume of corona discharge, the surface will ultimately develop local spark points, leading to local sparks at voltages lower than corona-forming values. Normally, however, with an initially clean rod and dust-free air inside the voltmeter, the surface of the rods in the corona voltmeter shows a most satisfactory degree of permanence.

V. Summary of Observations

From the complete data of which Table VII is a small portion, the values of the relative density δ are computed from Formula (3). The charging current galvanometer is calibrated directly in terms of current in the resistances R_1 and R_2 of Fig. 1. As already described, the readings of this galvanometer then lead through Formula (4) to the crest value of alternating voltage. From this value and the dimensions of the rod and the inner cylinder of the corona voltmeter, the critical or corona-forming electric intensity in kilovolts per centimeter at the surface of the conductor is readily computed. Some of these steps are given

in Table VII and the more important ones are collected in Table IX.

Table IX shows about one-fourth of the total number of derived values for computing the law of corona. The summary of all these values is given in Table X. Each reading of voltage in Table IX corresponds to four pairs of right and left galvanometer readings at each pressure, as set forth in Table VII. It will be noted that on the average Table IX presents three sets of readings for each value of pressure. This means that for each pressure there are 12 observations of corona forming voltage. Table IX also includes both observed and computed values of $\frac{E}{\delta}$ and $\frac{1}{\sqrt{\delta\, r}}$, the latter based on the law of corona deduced from all the observations as set forth in the following section.

VI. The Law of Corona

As the work proceeded the values of $\frac{E}{\delta}$ and $\frac{1}{\sqrt{\delta\, r}}$ were plotted. It was found that the resulting curve was a straight line, in accordance with Formula (1), for the larger values of $\frac{1}{\sqrt{\delta\, r}}$. However, on extending the study to larger corona rods, and especially at the higher pressures, it was found that the points departed from the straight line indicated for smaller rods and lower pressures. This fact at first was quite disturbing as it suggested either a departure from the simple law of Formula (1) or the presence of some error in method or observation. Many readings were repeated but resulted only in confirming the earlier ones.

Further study and investigation of the foregoing interesting results led to the work of Whitehead and Brown[6] on "The Corona at Continuous Voltages," which shows that while both the positive and negative corona obey a law of the form of Formula (1), yet the constants A and B are different in the two cases. This means that if the law for each case is put into the form of the linear relation between $\frac{E}{\delta}$ and $\frac{1}{\sqrt{\delta\, r}}$ the two lines will intersect and that below the point of intersection negative corona appears first, while above the point of intersection positive corona appears first.

Extending the foregoing to corona formation at alternating voltage, we should find, if we plot between $\frac{E}{\delta}$ and $\frac{1}{\sqrt{\delta\, r}}$ that below the value $\frac{1}{\sqrt{\delta\, r}} = 2.25$, representing the intersection of the positive and negative corona curves, the alternating corona should obey the same law as the negative continuous corona and that above that value it should obey the law found for positive corona. This is exactly the result that we have found and it therefore constitutes a necessary, and in fact important, modification of the law of corona.

The foregoing conclusions are immediately obvious if all of the observations are plotted, and as the results are very consistent throughout, a quite close approximation to the exact values of the constants of Formula (1) is possible by this graphical method. However, it is obviously better to derive the values of these constants from the figures themselves, and for this purpose the "Sigma-Delta" method[12] for evaluating the constants, has been used.

If we attempt to apply the Sigma-Delta method to the entire set of observations, a part of which are given in Table IX, it becomes very laborious indeed. It appeared to us, therefore, that this could be avoided by a still further averaging of the results for one pressure corresponding to each of the groups of readings in Table IX, this averaging being done on the values of $\frac{E}{\delta}$ and $\frac{1}{\sqrt{\delta\, r}}$. There being a linear relation between these two quantities, no error is thereby introduced. In this way the values of Table X are reached. The first column of Table X gives the sequence numbers as used in the Sigma Delta method; the second and third columns the mean values of $\frac{1}{\sqrt{\delta\, r}}$ and $\frac{E}{\delta}$; the fourth column the calculated value of $\frac{E}{\delta}$ as derived from the Sigma-Delta method; and the fifth column the error as between observed and calculated values of $\frac{E}{\delta}$ expressed in per cent.

In applying the Sigma-Delta method to the figures of Table X it was thought best, in view of the uncertainty as to the exact point of intersection of the two straight lines referred to above, to omit the points in the immediate neighborhood of this point of intersection. Consequently the points were plotted, as shown in Fig. 16, and the approximate position of the point of intersection of the two lines thus determined roughly. This being done, the readings corresponding to values of $\frac{1}{\sqrt{\delta\, r}}$ between 1.9 and 2.3 were omitted from the computations for the reason mentioned. In this way the equation of the line below the point of intersection was determined from the first sixteen readings of Table X, comprising the interval 1.253 to 1.870, for $\frac{1}{\sqrt{\delta\, r}}$. There are twenty-eight readings above the point of intersection comprising values from 2.375 to

6.254 for $\frac{1}{\sqrt{\delta\, r}}$. These were used for determining the equation of the line above the point of intersection. The results of the computation give the following formulas:

For values of $\frac{1}{\sqrt{\delta\, r}}$ below 2.295 and in this range range negative corona appears first:

$$\frac{E}{\delta} = 29.87 + \frac{9.918}{\sqrt{\delta\, r}} \tag{7}$$

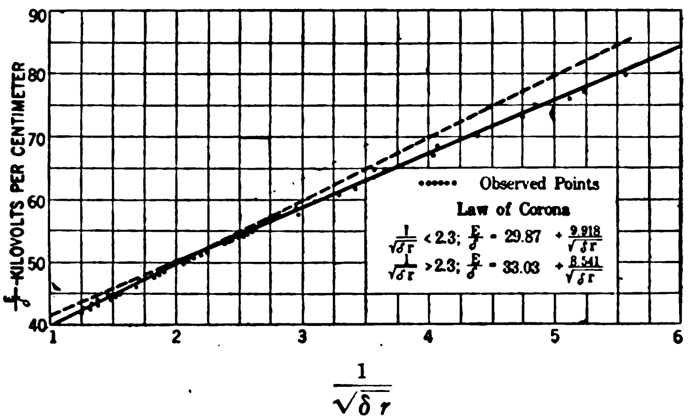

Fig. 16—The Law of Corona

For values of $\frac{1}{\sqrt{\delta\, r}}$ above 2.295 and in this range positive corona appears first:

$$\frac{E}{\delta} = 33.03 + \frac{8.541}{\sqrt{\delta\, r}} \tag{8}$$

The point of intersection of the two lines is $\frac{1}{\sqrt{\delta\, r}}$ = 2.295 corresponding to a value of $\frac{E}{\delta}$ = 52.62.

It is interesting to note in connection with Fig. 16 that observations on two of the rods used (0.238-cm. and 0.157-cm. radii) give several points each on both sides of the point of intersection of the two lines.

The extension of the observations in the direction of larger values of $\frac{1}{\sqrt{\delta\, r}}$ was readily accomplished by using smaller rods and lower pressures. The extreme values in this direction were reached in using a 0.0519-cm. diameter rod and an absolute pressure of 36 cm. of mercury giving the value 6.28 for $\frac{1}{\sqrt{\delta\, r}}$.

In the opposite direction, *i. e.*, smaller values of $\frac{1}{\sqrt{\delta\, r}}$ there is also a wide range possible in increasing the pressure and using larger rods. Our largest rod was 0.633-cm. radius and our greatest pressure about about 135-cm. mercury, giving 1.25 for $\frac{1}{\sqrt{\delta\, r}}$. As indicated elsewhere, larger rods are not desirable, but obviously much higher pressures can be used. Our limit in this direction was found in the break-down voltage of the air condenser, precluding precision measurements below 1.25 for $\frac{1}{\sqrt{\delta\, r}}$. However, we have made a number of observations of the performance of the corona voltmeter at higher pressures, with the precision voltage measurement omitted, and have found nothing to suggest a departure from the simple linear relation indicated in Formula (7) and Fig. 16.

VII. Advantages of the Corona Voltmeter as a Standard

The law expressed in Formulas (7) and (8) constitutes a definite standard over a wide range of voltage.

The range has been tested by precision measurements up to the neighborhood of 150,000 volts and with every evidence that the law continues beyond that value. The only quantities which enter are the radius of the corona rod, the radius of the outer cylinder, and the density of atmospheric air. This is equivalent to saying that the calibration of the corona voltmeter depends only on its physical dimensions.

As regards its availability in practical measurements, a workable corona voltmeter may be set up in practically any laboratory with very little trouble. A straight clean wire stretched on the axis of a surrounding metal cylinder will give very reliable indications in a darkened room with a visual observation of corona formation. With little additional trouble a galvanometer may be used as corona indicator. A considerable although not a continuous, range may be had by using corona wires of different diameters.

The construction of the complete corona voltmeter itself, moreover, is a relatively simple and inexpensive matter. Up to 100,000 volts it may be readily constructed in any well-equipped laboratory and for higher ranges offers no serious difficulties. With the complete instrument a wide and continuous voltage setting is available using a single rod and observations sharply marked may be taken with an ordinary laboratory galvanometer or with a telephone receiver.

The usual method of setting for a definite voltage is to read the temperature inside the instrument, set the pressure at a particular value based on the value of δ, corresponding to the desired voltage setting, and which may be read from a table based on Formulas (7) and (8) and then slowly raise the voltage until corona appears, as indicated by telephone or galvanometer. While this would probably be the more common usage in connection with insulation testing and other similar service, the instrument may also be used for measuring an unknown voltage. In this case the pressure would be set for a voltage known to be higher than that to be measured and the pressure then allowed to fall slowly, its value being read at the instant corona appears. Formulas (7) and (8), or tables computed from them, would then give the value of the voltage.

The corona voltmeter would appear to have several advantages over the needle and sphere gaps; among them may be mentioned the following:

(a) Freedom from disturbance by proximity of neighboring conductors or extraneous electrostatic fields.

(b) A 2 per cent inaccuracy is the minimum claimed for the sphere gap. With careful manipulation and good circuit conditions it is certain that a corresponding figure of better than 0.5 per cent is possible with the corona voltmeter.

(c) No manipulation of high-voltage circuit. Each change of setting of the sphere gap requires altering the distance between the discharge spheres. The setting of the corona voltmeter for different voltages requires the change of air pressure only.

(d) No discharge of high-voltage circuit and no series resistance necessary. The reading of the corona voltmeter is continuous and stationary and draws no current from the high-voltage circuit.

(e) Measurement of an unknown voltage. This cannot be done with the sphere gap except through repeated opening of circuit and successive approximation.

(f) All parts of the corona voltmeter are grounded except the leading-in wire of the high-tension terminal. All dimensions remained fixed. All auxiliary circuits are at low values of continuous voltage.

(g) Permanence. The surface of a corona-forming rod remains unaffected under the continuous application of initial corona over long periods.

As regards outside dimensions, the earlier paper[1] on the corona voltmeter described a corona voltmeter for voltages under 50,000 having dimensions of 76 cm. in length and 24 cm. in diameter. The instrument shown in Fig. 9 is 9 ft. 10 in. high (of which 3 ft. is in the insulating bushing) and 1 ft. 10 in. in diameter. The inside cylinder forming the grounded terminal is 24.6 cm. in diameter and 61 cm. long. The most convenient diameters of corona rod are between 0.3 cm. and 0.9 cm. This instrument has been used for voltages up to 150,000 volts without sign of distress, this being the maximum voltage obtainable under the conditions of test. It was used for this voltage at an internal air pressure of about 135 cm. of mercury absolute, *i. e.*, not quite 15 lb. per sq. in. above atmosphere. Pressures three or four times this value could readily be used. The limiting voltage would probably be found in the flash-over voltage of the insulating terminal bushing. This bushing has a normal rating of 150,000 volts effective. It is probable therefore that the instrument shown in Fig. 9 may safely be operated without trouble to 200,000 volts maximum value.

An instrument rated normally at 300,000 volts, and which it is expected may reach 400,000 volts, is now in process of construction.

THE DISADVANTAGES OF DURABILITY

There are certain industries which thrive on fragility; lack of durability and liability to breakage are cardinal to their prosperity; readers of Arnold Bennett will remember the play he makes in one book of the huge enjoyment of a pottery town audience, when, at a theatre, crockery smashing was in evidence; but apart from porcelain whose fragility sustains an industry by replacement. large numbers of manufactured articles are meant to enjoy only a transient and brief existence. In only one instance can engineering products be compared with those articles intended for early obsolescence, upon which, if current report be true, certain prosperous businesses are founded; this is in the case of spares whose cost is in many cases ominously high. It is not so much that the original device was ill-made, as that wear having taken place the customer is exploited because he is defenceless.

Durability is fundamental to mechanical construction, not that it is destined for eternity, but that in general it is proof against easy disaster and enjoys a reasonable span of life. Some engineering products certainly do survive a long term of service, longer in fact than their makers ever contemplated, renewals and demands for spares for very ancient plants are within the knowledge of any old established firm of reputation. While such orders are a testimonial in themselves, they invoke rather mixed feelings; had the job been less durable there would be prospect of entire replacement and more business.

Point is lent to the foregoing by the evidence before the recent Traffic Commission; it was then stated, and subsequent private inquiry confirms the statement, that no tram car belonging to the London County Council had ever been scrapped; they had been over-

hauled, repaired and periodically put into serviceable condition, but the whole number purchased were still in commission. Such a statement may invoke mingled feelings among the general public, since as ratepayers they may feel that their property is being conserved in their interests, or as passengers they may feel that their comfort is being sacrificed to parsimony; and that perhaps their journeys might be expedited if total renewal took place after a determined period. Something stronger might be said as to other means of transport, there are certain railways, for example, where archaic survivals are notorious. The term of service and survival permitted to public vehicles has few other parallels.

In machine-shop practise, although a more enlightened policy is now in evidence, antiquated survivals are pretty numerous, instances of tools approaching threescore years and ten were, not so long ago, quite ordinary, and the wisdom of such retention is questionable. The testimony to the maker is undeniable, but the profit to the user is another story altogether. Even in a time of soaring prices the retention of the obsolete has little merit, and never more so than in a time of reconstruction, when business has to be re-erected and re-won. In the matter of machine tools the need is less obvious than in power plant where running costs receive closer scrutiny, and return on capital outlay is more conspicuous. The modern analysis of power plant is very thorough and there are many rival prime movers. The business of an engineer is strictly economic, involving as it does a nicely balanced mind which senses relative proportion; on the one hand it is possible always to renew, recondition, and overhaul existing plant; on the other, every single individual will agree with the abstract proposition that there is a time in the life of every piece of mechanism when it should be discarded altogether. It is false economy to retain the obsolete, if it is not sheer parsimony, for by economic test its space otherwise filled would result in a gain on balance; the passage of time alone involves replacement if there is any virtue in evolution.

All firms who desire to be solvent have a depreciation account, of which they make the most to the representative of the Inland Revenue, and severe official attitude in restraint of exuberant writing down, adds to the contents of the national treasury. The point is, does this adjustment of income-tax in the form of abatement get duly applied to actual renewal? It is contended that at least the amount of such allowance should actually be spent in a definite policy of replacement, irrespective of whether or not the existing plant can be made to serve another term.

There is value in the policy indicated, in the place of piling up a reserve for contingency which is better employed in improving means of productive output. The assets are undeniable in either case, except that the interest earned by up-to-date gear is likely to be much the greater. Many shops are aware of the precaution of renewal and pursue a definite program but there are others less well advised. The old proverb about the shoemaker's wife contains more than a grain of truth.

In certain cases which have a bearing on the subject, machines are in existence (more particularly in agriculture) where the whole of the original has disappeared; every season portions are replaced until virtually nothing remains; the cost of such replacement is out of all proportion to initial value and illustrates one danger of easy spares facilities, the same can easily be true of motor vehicles, and a large trade in spares is valuable considering the prices charged.

Again, a parsimonious spirit defeats itself; in how many instances, when control has been vested in such an individual, has his successor to put right the lack, by royal spending. The first man took credit for economy; the second points out that to save, it is necessary to spend; both can allege reason for their views, difference of opinion would be avoided by laying down a rational program.

Actuarial assessment on the assurance principle of probable expectation of life seems feasible, the annual depreciation account indicates as much, what is wanted in many cases is execution of its provisions by term discard and renewal. To bring the old servant in the form of machine-tool or plant, to the sacrificial altar of the cupola perchance needs courage, but sentiment in such connections is out of place and iconoclasm in order; careful selection of a modern successor has advantages easily realized upon due reflection.—*Engineering*, London.

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

Calvert Townley, Chairman, 165 Broadway, New York.
N. A. Carle, W. A. Hall, George A. Hamilton,
L. F. Morehouse, W. I. Slichter, C. E. Skinner.

FINANCE COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Hall, L. F. Morehouse.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
L. W. Chubb, E. E. F. Creighton, John H. Finney,
L. R. Jorgensen.
Chairman of Committee on Technical Activities, the chairmen of all technical committees, and the chairmen of all Sections.

PUBLICATION COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
N. A. Carle, Wm. A. Del Mar, F. L. Hutchinson
Harold Pender

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
H. N. Latey, J. H. Morecroft, Wm. S. Murray,
H. H. Norris, E. M. Sawtelle, Clayton H. Sharp,
Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, Murray & Tregurtha Corp., Atlantic, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd,
and the chairmen of all Institute Sections *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker,
Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose,
G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb,
A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins,
D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 20 Nassau St., New York.
F. B. Crocker, Vice-President,
James Burke, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.

Comfort A. Adams	H. W. Fisher,	David B. Rushmore,
P. G. Agnew	H. M. Hobart,	Charles F. Scott,
B. A. Behrend,	Dugald C. Jackson,	Clayton H. Sharp
John J. Carty,	B. G. Lamme,	C. E. Skinner,
L. W. Chubb,	W. S. Moody,	S. W. Stratton,
W. A. Del Mar,	A. H. Moore,	Elihu Thomson,
Gano Dunn,	Charles Robbins,	R. B. Williamson.
Walter C. Fish,	E. B. Rosa,	

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.

J. C. Forsyth,	H. B. Gear,	H. O. Lacount,
Johnston Livingston,	M. G. Lloyd,	R. W. E. Moore,
Henry N. Muller,	H. R. Sargent,	G. A. Sawin,
A. M. Schoen,	George F. Sever,	H. S. Warren.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, L. B. Stillwell,
Schuyler Skaats Wheeler.

BOARD'S COMMITTEE ON TECHNICAL ACTIVITIES

Wilfred Sykes, Chairman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
G. Faccioli, W. I. Slichter.

STANDARDS COMMITTEE

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
E. J. Cheney, Secretary, Public Service Commission, Albany, N. Y.

P. G. Agnew,	G. A. Anderegg,	Frederick Bedell,
L. P. Blume,	James Burke,	G. A. Burnham,
P. H. Chase,	H. H. Clark,	F. P. Cox,
E. B. Craft,	W. A. Del Mar,	F. M. Farmer,
H. W. Fisher,	F. C. Hanker,	H. M. Hobart,
H. H. Humphrey,	H. D. James,	P. Junkersfeld,
A. E. Kennelly,	G. L. Knight,	R. W. Krass,
C. O. Mailloux,	C. S. McDowell,	W. L. Merrill,
Taliaferro Milton	L. F. Morehouse	F. D. Newbury,
H. S. Osborne,	S. G. Rhodes,	Charles Robbins,
R. F. Schuchardt,	C. E. Skinner,	A. B. Smith,
John B. Taylor,	A. H. Timmerman,	W. K. Vanderpoel,
	R. B. Williamson.	

EDISON MEDAL COMMITTEE

(Appointed by the President for terms of five years)

	(Term expires July 31, 1920.)	
Carl Hering, Chairman,	Harris J. Ryan,	Robert Lindsay.
	(Term expires July 31, 1921.)	
W. C. L. Eglin,	Bancroft Gherardi,	E. W. Rice, Jr.
	(Term expires July 31, 1922.)	
Comfort A. Adams,	L. A. Ferguson,	S. W Stratton.
	(Term expires July 31, 1923.)	
Frederick Bedell,	L. T. Robinson,	Calvert Townley.
	(Term expires July 31, 1924.)	
E. D. Adams,	H. H. Barnes,	B. G. Lamme.

Elected by the Board of Directors from its own membership for terms of two years.

	(Term expires July 31, 1920.)	
Charles Robbins,	C. E. Skinner,	W. I. Slichter.
	(Term expires July 31, 1921.)	
G. Faccioli,	W. A. Hall,	Wilfred Sykes.

Ex-Officio

Calvert Townley, President, George A. Hamilton, Treasurer.
F. L. Hutchinson, Secretary.

SPECIAL COMMITTEE

COMMITTEE ON DEVELOPMENT

Charles F. Scott, Chairman, Sheffield Scientific School, Yale University, New Haven, Conn.

F. F. Brand, Pittsfield, Mass.
J. C. Clark, San Francisco, Cal.
Ira M. Cushing, Boston, Mass.
W. A. Del Mar, New York, N. Y.
H. W. Eales, St. Louis, Mo.
F. R. Ewart, Toronto, Ont.
W. A. Hall, Atlantic, Mass.
W. F. James, Philadelphia, Pa.
Leslie Killam, Milwaukee, Wis.
P. M. Lincoln, Cleveland, O.
A. S. MacDowell, Rochester, N. Y.
H. T. Plumb, Salt Lake City, Utah.
A. M. Schoen, Atlanta, Ga.
C. H. Schum, Erie, Pa.
Samuel Sheldon, Brooklyn, N. Y.
N. W. Storer, Pittsburgh, Pa.
H. L. Wallau, Cleveland, O.
J. Lloyd Wayne, Indianapolis, Ind.
H. E. Bussey, Atlanta, Ga.
Clem A. Copeland, Los Angeles, Cal.
R. H. Dalgleish, Washington, D. C.
F. G. Dustin, Minneapolis, Minn.
H. S. Evans, Boulder, Colo.
Baxter R. Grier, Gatun, C. Z.
John Harisberger, Seattle, Wash.
V. Karapetoff, Ithaca, N. Y.
J. J. Kline, Fort Wayne, Ind.
Chas. A. Lund, Spokane, Wash.
John C. Parker, Ann Arbor, Mich.
L. T. Robinson, Schenectady, N. Y.
R. F. Schuchardt, Chicago, Ill.
W. D. Scott, Portland, Ore.
G. E. Snider, Toledo, O.
L. E. Underwood, W. Lynn, Mass.
J. W. Watson, Madison, Wis.
J. B. Whitehead, Baltimore, Md.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, 644 Riverside Drive, New York.
H. V. Bozell, John B. Fisken, W. S. Gorsuch, L. G. Ireland, A. H. Kruesi, J. F. Meyer, S. G. Rhodes, Allard Smith, E. H. Sniffen, P. B. Yates.

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.
C. R. Dooley, F. F. Fowle, Charles S. Howe, C. E. Magnusson, E. B. Merriam, L. F. Morehouse, G. H. Pfeiff, H. W. Price, R. F. Schuchardt, W. I. Slichter, William R. Work.

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.
James Burke, Alexander Churchward, A. M. Dudley, C. E. Eveleth, G. Faccioli, B. G. Lamme, A. C. Lanier, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.
F. F. Ambuhl, E. R. Berry, Joseph L. Dixon, I. R. Edmands, L. E. Imlay, F. A. Lidbury, W. R. Whitney, J. L. Yardley.

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
P. G. Agnew, H. D. Arnold, E. F. Burton, L. W. Chubb, J. C. Clark, C. P. Eldred, E. P. Hyde, Chester W. Rice, C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.
P. H. Adams, E. V. Buchanan, H. W. Cope, Wm. E. Date, James Dixon, A. M. Dudley, R. H. Goodwillie, H. D. James, W. C. Kalb, R. H. McLain, E. H. Martindale, A. H. Timmerman, L. E. Underwood, H. Weichsel, R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 124 E. 15th St., New York.
C. W. Baker, Wm. M. Bradshaw, H. B. Brooks, F. P. Cox, F. V. Magelhaes, Charles Robbins, Clayton H. Sharp.

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.
F. B. Crosby, F. D. Egan, Gordon Fox, Eugene Friedlaender, E. S. Jefferies, W. C. Kennedy, D. M. Petty, Wm. T. Snyder, Wilfred Sykes, R. B. Williamson, Fred H. Woodhull, J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. N. Chamberlin, J. R. Cravath, Terrell Croft, N. S. Dickinson, Bassett Jones, F. D. Newbury, P. G. Nutting, R. C. Powell, E. B. Rosa, W. D'A. Ryan, W. M. Skiff, G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.
R. A. Beekman, Eskil Berg, A. R. Cheyney, Maxwell W. Day, E. G. Gallagher, H. L. Hibbard, W. F. James, C. A. Jones, C. S. McDowell, W. F. Meschenmoser, I. H. Osborne, G. A. Pierce, Jr., J. B. Porter, L. B. Sinclair, H. M. Southgate, Wilfred Sykes, W. E. Thau, A. E. Waller, F. W. Wood.

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.
R. T. Andrae, F. H. Armstrong, Graham Bright, L. C. Ilsley, R. L. Kingsland, A. B. Kiser, Wills Maclachlan, E. B. Woodward.

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.
J. T. Barron, A. E. Bauhan, E. T. Brandon, H. W. Eales, W. L. R. Emmet, W. S. Gorsuch, H. P. Liversidge, I. E. Moultrop, Frank D. Newbury, H. S. Putnam, R. F. Schuchardt, Russell W. Stovel, H. L. Wallau, R. B. Williamson.

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.
G. E. Armstrong, P. H. Chase, W. H. Cole, E. E. F. Creighton, H. W. Eales, F. C. Hanker, E. M. Hewlett, F. L. Hunt, P. MacGahan, D. A. McKenzie, A. A. Meyer, L. C. Nicholson, N. L. Pollard, F. E. Ricketts, Charles Robbins, T. C. Taliaferro, H. R. Woodrow.

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 253 Broadway, New York.
O. B. Blackwell, R. E. Chetwood, E. H. Colpitts, H. W. Drake, W. B. Kouwenhoven, L. F. Morehouse, R. W. Osborne, W. O. Pennell, L. M. Potts, S. A. Rhodes, A. B. Smith, D. M. Therrell, W. H. Winter, D. E. Wiseman.

TRACTION AND TRANSPORTATION

W. S. Murray, Chairman, Room 2800, 165 Broadway, New York.
A. H. Babcock, Reinier Beeuwkes, R. H. Dalgleish, W. G. Gordon, John Murphy, W. B. Potter, Ralph H. Rice, Guy A. Richardson, C. S. Ruffner, N. W. Storer, H. M. Warren.

TRANSMISSION AND DISTRIBUTION

Edward B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
J. E. Woodbridge, Vice-Chairman, 58 Sutter St. San Francisco, Cal.
R. W. Atkinson, A. O. Austin, Wallace S. Clark, W. H. Cole, A. W. Copley, M. T. Crawford, E. E. F. Creighton, F. E. Ricketts, D. W. Roper, C. S. Ruffner, R. F. Schuchardt, A. E. Silver, W. K. Vanderpoel, C. T. Wilkinson.

INSTITUTE REPRESENTATIVES

ON AMERICAN BUREAU OF WELDING

W. L. Merrill.

ON AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, Wm. S. Murray, F. N. Waterman.

ON AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart, C. E. Skinner.

ON AMERICAN YEAR-BOOK ADVISORY BOARD

Edward Caldwell.

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon, Calvert Townley.

ON COMMISSION OF WASHINGTON AWARD

John Price Jackson, Charles F. Scott.

ON COUNCIL OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

H. H. Humphrey, John B. Taylor.

ON ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle, Charles S. Ruffner, C. E. Skinner.

ON ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

ON FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt, L. B. Stillwell.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, Calvert Townley, E. W. Rice, Jr.

ON JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, Samuel Sheldon.

ON JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATOR PINS

J. T. Barron.

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle, Samuel Sheldon, W. I. Slichter.

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood, Percy H. Thomas.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams. Frank B. Jewett. W. R. Whitney.

ON NAVAL CONSULTING BOARD

Benjamin G. Lamme. Frank J. Sprague.

ON SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

P. G. Agnew. F. Conrad. P. P. Cox.
F. C. Holtz. A. E. Kennelly. Farley Osgood.
S. G. Rhodes.

ON U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly. C. O. Mailloux. Clayton H. Sharp.

Characteristics and Performance of Arc Welding Machinery

BY A. M. CANDY

Engineering Department, Westinghouse Electric & Mfg. Co.

THIS paper deals rather briefly at first with the earlier history of arc welding apparatus discussing the increased efficiency of the constant-potential welding circuit and decreased size and cost of the apparatus by changing the generated circuit potential from 75 to 60 volts. Curves are given showing the efficiency increase and also the disadvantages attending any material decrease of the circuit potential below 60 volts.

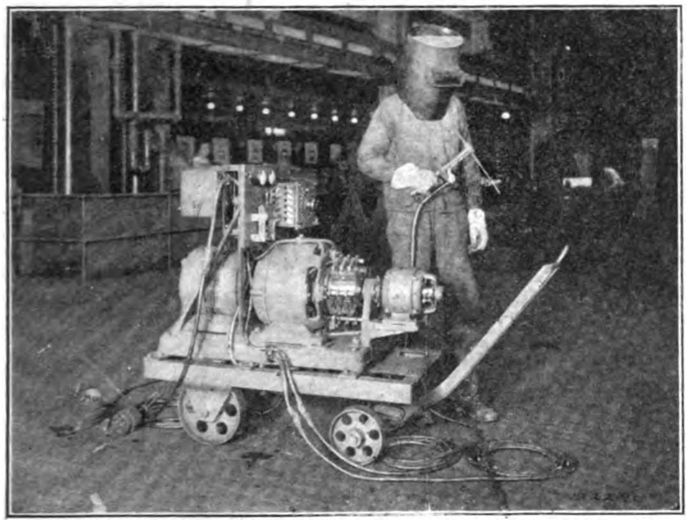

FIG. 7

The discussion then turns to the more recent developments of variable-voltage or constant-current equipment of both the alternating and direct current types. Although the a-c. arc welding transformer is about one-half as heavy and expensive as the d-c. equipment its use at present and in the immediate future at least will be relatively limited for several reasons.

1. To make the equipment commercially successful in the hands of the average welder it is necessary to use an especially prepared electrode.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

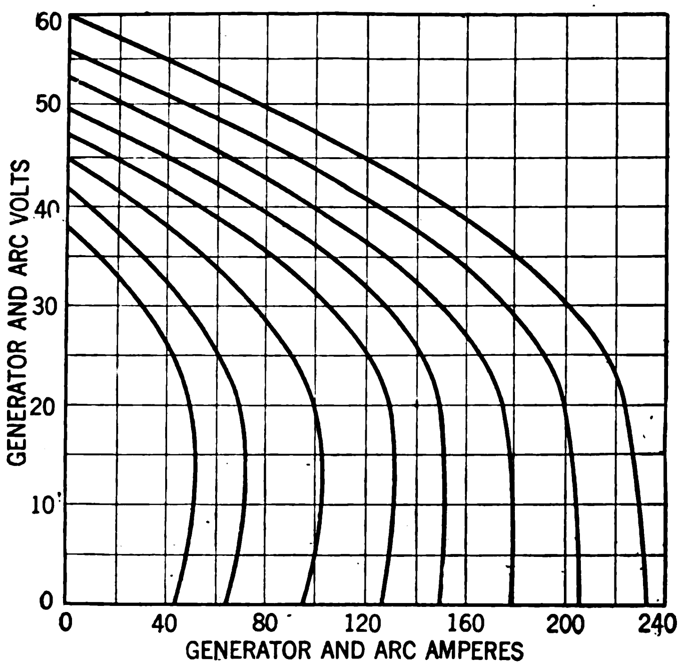

FIG. 5—SINGLE-OPERATOR ARC WELDER—VOLT-AMPERE CHARACTERISTIC

2. The alternating current arc is not so effective in fusing metal as the direct current arc assuming the same current in amperes in each case. In other words, to obtain the same rate of fusion the ratio of alterna-

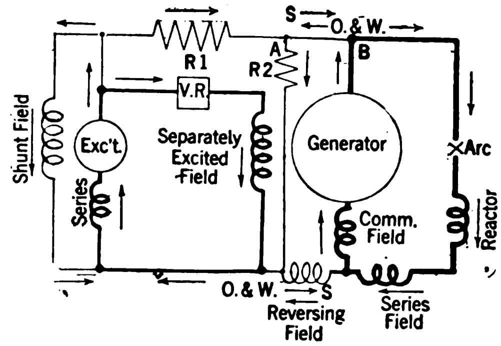

FIG. 8

ting current to direct current required is in the order of 170 amperes a-c. to 140 amperes d-c.

3. The transformer is inherently a single-phase low power factor load (20 per cent to 30 per cent maximum). This characteristic is necessary so that the arc will be reasonably stable.

The first two features make the operating cost so much higher than for the interconnected constant-current d-c. machine that the saving in operating cost per annum will be about 50 per cent interest on the difference of the first costs of the two types.

4. No thoroughly satisfactory means of limiting the open-circuit voltage to reasonably safe values (60 volts or less) has as yet been developed. To be commercially satisfactory the transformer must either actually develop or have the characteristics of an open-circuit potential of 135 volts minimum to 175 volts maximum.

This potential is higher than the operator should be subjected to as it is a real life hazard.

The main portion of the paper discusses an interconnected constant-current variable-voltage d-c. generator and exciter (see Fig. 7.) which has been developed and placed on the market quite recently. The generator is a commutating-pole machine provided with a series of field winding, a shunt field winding separately excited continually by means of a small exciter coupled to the generator shaft, and a second hunt field winding connected to both the generator terminals, and the exciter terminals so that under open-circuit and normal welding conditions it is self-excited by the generator voltage, whereas under short-circuited arc condition it is excited in the opposite direction by current from the exciter terminals. This field winding is therefore logically called a reversing field. The series field is connected so that it always opposes the separately excited field. Under open circuit and normal welding conditions the reversing field (self excited by generator) assists the separate field in maintaining the generator voltage. Under short circuited arc conditions the reversing field is excited by current from the exciter so that it functions as a separately excited field and assists the series in opposing the separate field thereby limiting the generator voltage to a value such that the short-circuit current is substantially the same as the normal welding current. This characteristic is illustrated by Fig. 5. The scheme of connections producing these characteristics is illustrated by Fig. 8. A very decided advantage of this interconnected scheme is the fact that the arc is given the advantage of the constant potential continually developed by the exciter although the generator terminal voltage is never above 60 and varies from that value down to practically zero when short circuited.

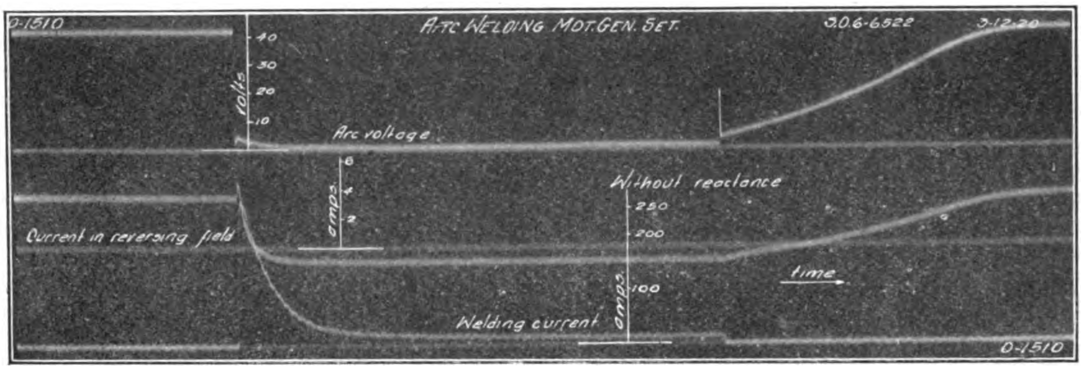

FIG. 10

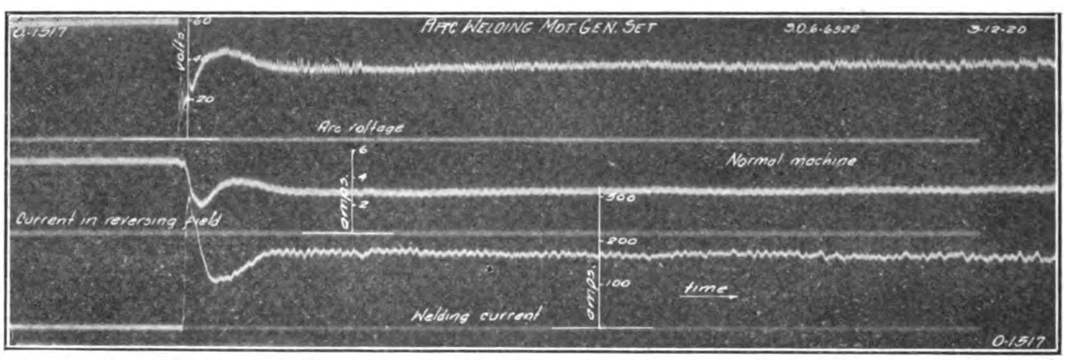

FIG. 18

A portion of the exciter voltage exists across the electrode terminals instantly when they are separated by the operator incident to striking the arc, thereby materially assisting him in starting the arc regardless of any lag in the generator building up its voltage. Furthermore, this impressed constant potential from the exciter circuit helps to stabilize the arc making it

exceptionally tenacious. Both of these features are of very material assistance to the welding operator. The latter characteristic is illustrated by Fig. 10 where the kick in the generator terminal voltage is indicated when the arc current was broken suddenly by deliberately separating the electrodes quickly.

Another feature of this machine is that it can be successfully used for graphite electrode welding, delivering 150 amperes at 40 volts, as illustrated by Fig. 18. Where more than 150 amperes is required two or more equipments can be operated in parallel by simply connecting together the external leads of like polarity of the generators. Due to the characteristics of the generator no equalizing connections are necessary.

Due to the elimination of losses in resistances in series with the arc the operating cost for the interconnected constant-current machine is considerably less than for the 60 volt constant-potential equipments and of course proportionally smaller than for 75-volt constant potentia lequipments. A curve and typical example comparing the operating cost of six interconnected machines with that of a 1000-ampere, 60-volt machine feeding six welding circuits are given. The figures show that although there is a difference in first cost of approximately $2050 in favor of the 1000 ampere equipment, under normal average operating conditions where central station a-c. service is 3 cents a kw-hr. the annual saving resulting from the use of the interconnected equipments is equivalent to practically 60 per cent interest on the additional investment of $2050.

Summary of the advantages of the interconnected constant-current scheme,

1. Ease of striking arc.
2. Ease of holding arc due to increased stability.
3. Operating expense less than for other types of equipment.
4. Simplicity of obtaining current adjustment.
5. Generator polarity cannot be reversed even though exciter circuit should be accidentally opened.
6. Two or more generators may be operated in parallel for graphite welding without requiring equalizer connections.
7. A maximum of 225 amperes for metal electrode and 150 amperes for graphite can be obtained from one generator.

Recent Developments in Electro-Percussive Welding

BY DOUGLAS F. MINER

Westinghouse Electric & Mfg. Co.

Condenser Type of Welder

FOLLOWING the original experiments of Mr. L. W. Chubb in 1905, machines were built for welding wires by the electro-percussive process and these have been used in a limited way for lamp leads, copper terminals on aluminum coils and similar applications.

These machines utilize the discharge of an electrolytic condenser to fuse the wires substantially simultaneous with a percussive engagement. With this equipment, perfect welds are made between like and unlike metals, even those of widely different physical characteristics, but the field of application has been narrow because of the state of development of condensers. A condenser of sufficient capacity to provide energy for welding large sections would be prohibitive in size.

Electromagnetic Type of Welder

Within the last year, equipment has been developed which successfully welds stock up to ½ in. (1.27 cm.) diameter, and large sizes will apparently offer no difficulty. The same principles are used in this device, but stored electromagnetic energy replaces electrostatic energy. Establishment of a strong direct-current field in a reactance coil with a primary and secondary winding is followed by rupture of the primary current with the secondary circuit closed. Transfer of energy of the collapsing field to the secondary results and a subsequent separation of electrodes in this circuit establishes

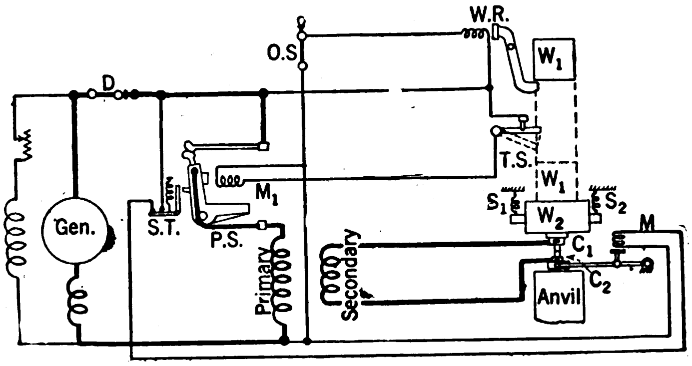

Fig. 2

an intense arc. When the surfaces of the electrodes (pieces to be welded) are sufficiently melted, a hammer forges the parts together.

The total time of the above operations is of the order of 1/10 second. Thus the weld can be said to be practically instantaneous. In an experimental welder, these events were secured in proper sequence by apparatus represented diagrammatically in Fig. 2. A cycle

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

of operations is somewhat as follows: The primary is energized by closing switch D which also raises the lower electrode C_2 into contact with C, by means of magnet M. Then operating switch $O\,S$ is opened and magnet $W\,R$ de-energized. The hammer falls and in its travel knocks out switch $T\,S$. This allows primary switch $P\,S$ to open, kicking out trip $S\,T$, which then opens the secondary circuit by allowing the lower electrode to drop to the anvil. An arc is thereby established until the hammer strikes W_2, forging the parts together.

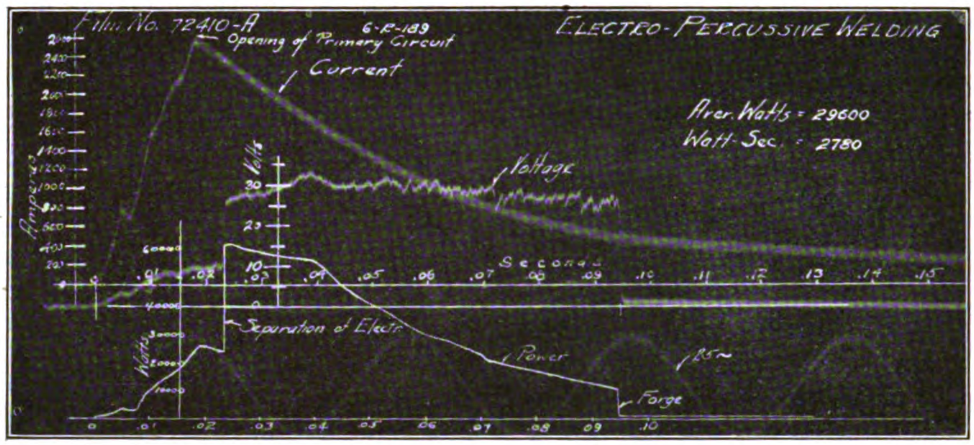

Fig. 5—Oscillogram of Electro-percussive Weld Between ⅜-in. Cold Rolled Steel and ⅜-in. Copper

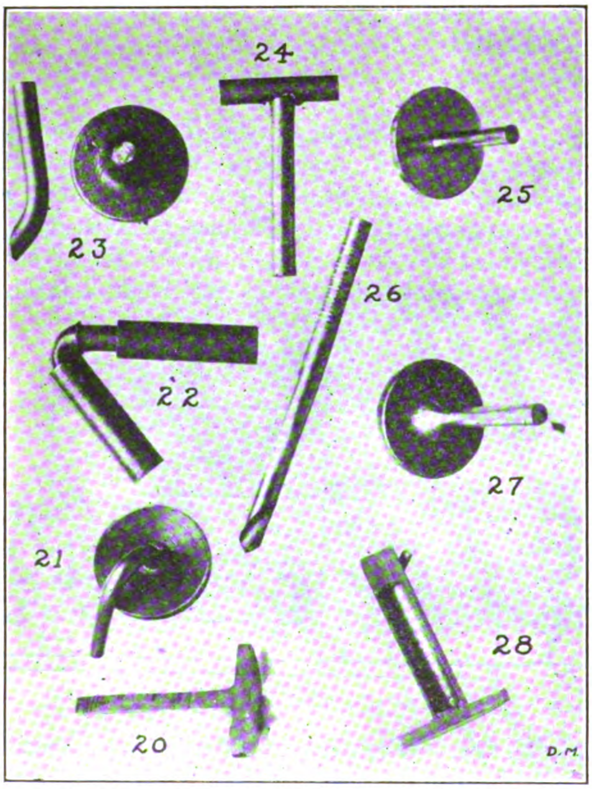

Fig. 9—Examples of Electro-percussive Welding

A record of events is given by the oscillogram Fig. 5. This indicates secondary quantities for a weld of 3/8 in, diameter stock and shows the following: Maximum secondary current 2600 amperes, arc voltage 30 volts, maximum watts 60,000, average watts 29,600, total time 0.094 seconds, energy 2780 watt-seconds or .00077 kw-hr.

A few sample welds are shown in Fig. 9, illustrating a variety of work.

20. ¼ in. copper rod welded to steel disk.
21. ¼ in. steel rod welded to steel disk and tested in bending without failure.
22. $\frac{5}{16}$ in. copper-copper weld bent sharply without failure.
23. Nickel-steel valve head welded to cold rolled steel stem. Failed in bending outside weld.
24. T-weld of cold rolled steel.
25. Cold rolled steel rod and disk polished.
26. $\frac{5}{16}$ in. drill lengthened with low carbon stock.
27. Nickel steel head to C. R. S. valve stem.
28. ½ in. hollow steel rod welded to steel plate.

Tests have shown a high strength of weld—96,000 lb. per sq. in. for steel-steel and 40,000 lb. per sq. in. for copper steel. Microphotographs confirm the quality of the weld and indicate an inter-penetration of metals, without visible alloying, and a thorough fusion without oxidation.

Advantages of Process

Some of the points of superiority of electro-percussive welding are:

(a) *Power Saved.* Power used in the weld is about $\frac{1}{16}$ that required in butt-welding*.

(b) *Time Saved.* The operation is so rapid that the time of weld is practically negligible. Speed of production will, therefore, depend chiefly on time of handling peices, and large output can be obtained by design of semi-automatic apparatus.

(c) *Welds of Unequal Sections.* Necessary energy is concentrated in a very small amount of material and not dissipated in heating the whole stock. Consequently welds of unequal section are possible

Electric Welding, D. Hamilton and E. Oberg P. 49.

without preparation of surfaces or preheating of large piece.

(d) *Welds of Unlike Metals.* with widely different physical characteristics are made possible.

(e) *Welds without Change of Condition.* Tempering or other treatments are not destroyed because heat is localized and rapid.

(f) *Welds Uniform.* After proper settings, unskilled labor can produce uniformly perfect welds.

(g) *Finishing* is unnecessary in some products and inexpensive in all because of small fin or flash.

Extension of the original process has met with gratifying success and when details of design are perfected, a wide field of application for electro-percussive welding is expected.

Credit is due C. F. Wagner and E. L. Hillstrom for aid in development.

Arc Welding Machinery of the U. S. Light & Heat Corporation

BY W. A. TURBAYNE

Electrical Engineer, U. S. Light & Heat Corporation

THE U. S. Light & Heat Corporation produces only the single-circuit or single-operator type of arc welding machine, wherein control of the current accompanying inverse changes in arc voltage and length is accomplished by inherent action of the machine windings, unaided by interposed circuit resistors.

In developing this equipment it was sought to reduce the machine and circuit losses to the lowest possible value compatible with practical operation, to obtain the quickest possible voltage response by the generator, or current converter, at the time of striking and manipulating the arc, and to insure the maintenance of a steady and stable arc, with a minimum amount of circuit reactance. It was also considered desirable to produce such a machine characteristic that the product of voltage and current would remain reasonably constant at the value best suited to the operation, despite the unavoidable variations in arc length incident to manipulation of the electrode in the hands of the operator. Provisions were incorporated, however, whereby by a simple adjustment, the slope of the volt-ampere characteristic could be altered in such a manner that practically a constant current would be maintained in the welding circuit, regardless of appreciable variations in arc length and voltage, this characteristic being favored by many operators.

Two distinct classes of arc welding machine were developed—one a *direct current generator* adapted to be separately driven by any form of motor, determined by the available source of power supply, and the other a *direct current converter* which is self driving when supplied from a direct current source having from 100 to 125 volts pressure.

The *generator* is a self-exciting, cumulative compound-wound machine, and current regulation is effected solely by the reaction of the armature current upon the field flux.

The relations between pole span and pole pitch and between the shunt and series field ampere turns are so chosen, with respect to the armature structure that, while a pronounced drooping voltage characteristic results, perfect circuit stability obtains at any value of current within the working range of the machine. A definite open-circuit voltage setting is inconsequential as the machine has a pronounced series characteristic, and a moderate variation in the shunt field current does not materially affect the current setting although such adjustment of the shunt field current affords a ready means of modifying the current values determined more or less broadly by means of a current-adjusting switch provided for the purpose.

To insure quick response to circuit conditions, the magnetic structure throughout is laminated, and the sensibility of the machine is decidedly enhanced by the inductive or transformer action resulting from the close association of the shunt and series field windings.

For operation on electric supply circuits, a compact motor-generator is furnished, induction motors of suitable voltage, phase and frequency being provided for use on a-c. circuits, and direct-current motors of appropriate voltage for d-c. supply.

The motors are direct connected to the generator, the rotor being pressed on the elongated armature shaft thereby eliminating the necessity for bolted couplings.

The complete running gear is supported on annular ball bearings and before assembly is thoroughly checked as to static and running balance.

Generators are also provided, direct connected to gasoline engines, or supplied merely with pulleys, enabling them to be driven from any available or suitable source of power.

For locations where 100 to 125-volt d-c. supply is available the *direct current converter* is recommended.

This machine has but a single magnet frame, arm-

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

ature winding and commutator, and combines within itself the functions of a shunt-wound motor and a variable-voltage generator. In size, weight and appearance it corresponds closely to the generator previously described. The complete field structure also is laminated.

The field system comprises two main poles supporting the shunt field winding and two smaller auxiliary poles, spaced at right angles thereto, which carry the regulating windings. These latter comprise a shunt winding connected across the supply circuit and an opposing series winding included in the welding circuit. A field rheostat is provided in the shunt circuit for purposes of adjustment.

The armature conductors are placed in slots located substantially 120 degrees apart around the periphery and are connected to the commutator to form an ordinary two-path winding with symmetrical end connections.

Four sets of brushes engage the commutator. Two sets, in line with the main poles and diametrically, opposed, admit current from the source to drive the machine. Two other sets, one each displaced 60 degrees from a main brush, together constitute one terminal of the welding circuit, the other terminal being the main brush midway between them.

Current regulation is effected by varying the flux distribution under the poles and, therefore, the voltage around the commutator by inherent action of the windings on the auxiliary poles. These auxiliary poles are of like polarity at any instant and, depending on the degree of their excitation, act to increase the flux density in one of the main poles while decreasing it in the other.

With the converter running idly as a motor, the open-circuit voltage effective on the secondary or working brushes is brought to the desired value by means of a field rheostat, provided for controlling the auxiliary shunt field current. Upon closing the welding circuit, however, current traverses the auxiliary series opposing winding, resulting in a decrease or even reversal of the flux in the auxiliary poles, a simultaneous lowering of the flux in one of the main poles and a corresponding increase in the other. This transfer of flux causes an immediate drop in voltage on the working brushes and corresponding increase across the remainder.

Two-thirds of the armature conductors at any instant carry only the input current, the other third carrying the difference between the output, or working current, and the input current. The resultant distribution of current, therefore, is such that conductors of comparatively small section may be employed as compared with those necessary in a generator of equivalent capacity.

During operation the current in the welding circuit comes, partly from the supply mains, this being the input current which drives the machine, the balance being contributed by the machine through generator action.

As a welder the direct-current converter shows an efficiency of 65 to 70 per cent. With 200 amperes and 20 volts at the welding arc the current demand from a 120-volt source is substantially 25 per cent of the value of the welding current or 50 amperes.

Differing from a generator, in which the flux in the complete structure is varied to produce regulation, the converter flux is simply transferred from one portion to another. Consequently, a notable freedom from lag exists.

Automatic Arc Welding Apparatus

BY S. R. BERGMAN and R. L. UNLAND

Both of General Electric Co.

AMONG the requirements which must be met by arc welding equipments are simplicity and reliability. Their importance is increased by the fact that in a great many cases these equipments are installed and operated in locations where no trained electrical help is available. A new type of arc welding generator is described which inherently possesses the electrical characteristics desirable for single operator arc welding generators. This results in the elimination of external resistors or other regulating devices since the generator delivers at its terminals the voltage required by the arc and the current for which the equipment is adjusted.

It has been found that a drooping volt ampere characteristic or a circuit in which the current decreases as the voltage increases, or vice versa, is advantageous for successful electric arc welding. This has been obtained in the past by the use of constant potential generators with a resistance in series with the arc to provide the drooping characteristic in the arc circuit. It has also been accomplished by using differentially wound generators with a separate excitation source to provide a stable magnetic circuit to act as a base for the regulation of the generator. In the generator described this result is accomplished by what may be called a dual magnetic circuit.

In the generator described the design consists of a four-pole field structure and an armature wound for two poles. The field poles are paired to give two adjacent poles of each polarity. The opposite field poles have the same character and are similarly connected in the electrical circuit so that variations in the

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

excitation occur simultaneously in the opposite poles and consequently the flux may be considered as two individual circuits, each of which passes through a pair of opposite poles, the armature and the field ring. These two fluxes are independent of each other as long as the magnetic structure common to both is not saturated. One of the magnetic circuits, referred to as the main field, is designed to provide constant flux and thereby maintain constant voltage in that portion of the armature under the influence of this field. The field poles in this circuit are designed to be saturated under normal conditions and therefore the flux will be very slightly affected by considerable variations in the electrical circuit. The other component of the field is at right angles to the first and is referred to as the cross field, and in this circuit the magnetic structure is not saturated. These two individual fields generate electromotive forces in the armature which under no-load conditions add arithmetically to provide the no-load voltage of the generator. As current is taken from the load brushes of the generator, however, an armature reaction is built up which may be resolved into two components at right angles, in line with the field fluxes described above. One component tends to increase the main field flux, the other component opposes the cross field flux. On account of saturation in the main field magnetic circuit further increase of flux is impossible, but in the cross field circuit the initial flux is reduced as the current and armature reaction increase and when the generator is finally short-circuited this flux is reversed to a value equal to the initial value. As the cross field is reduced and finally reversed it is obvious that the electromotive force generated in the armature by this flux also decreases and is finally reversed. The line voltage of the generator consists of the sum of these two voltage components. Under the no-load conditions they are equal and on short-circuit the component due to the cross field has the same value as at no-load but is reversed so that the terminal voltage of the generator is zero.

A differentially connected series winding is placed on the cross field poles to assist the armature reaction when it is desired to reduce the current output of this generator.

It is a simple matter to produce a generator which under steady load conditions has the drooping characteristic considered desirable for arc welding but when used for arc welding such machines fail due to slow regulation and the lag between the sudden variation in the arc and the corrective electrical or magnetic adjustment in the machine. It should be borne in mind that the regulation of this generator is mainly produced by the armature itself. Since the armature is the seat of the induced voltage it is obvious that if the armature itself is the seat of the regulating power this action is as intimate as can be obtained.

A new development is also described which takes the form of a device for automatically feeding a bare wire electrode into the welding arc at the exact rate required to maintain constant electrical conditions in the arc. This device consists of a small direct-current motor geared to feed rolls and electrically connected across the welding arc through control with the result that the speed of the motor and consequently the rate at which the wire is fed into the arc varies with the voltage across the arc. The result is that practically constant voltage is maintained across the arc and therefore the current will be constant. The arc voltage may be maintained below any value which is possible with hand manipulation of the electrode, and due to the steadiness of operation the speed of welding may be greatly increased over that obtained by hand. The length of the arc can be maintained at a minimum with the result that the metal has little opportunity of being oxidized in passing through the arc and the metal deposited is therefore of a higher and more uniform quality than that found where hand operation is used. The field for this device is limited to manufacturing production where the number of duplicate welds is sufficient to warrant the making of special fixtures for holding the work and for facilitating handling. Illustrations of work performed and operating data are given.

STATUS OF THE WATER POWER BILL

The Water Power Bill was reported back to the Senate and House after agreement by the conferees. The House promptly accepted the conference report after a short debate by a decisive vote of 259 to 30. In the natural course of events this practically assured the early passage of the bill into law but quite a formidable filibuster has developed in the Senate. When this issue goes to press, it appears that the bill is in serious danger unless the conferees make further changes in it.

It will be recalled that the bill has had a treacherous path through many sessions of Congress and that it was lost by a narrow margin in the filibuster and legislative jam that came at the end of the last session of Congress. Those in favor of the measure, however, are in hopes of forcing a vote.

It will also be recalled that after passage of this bill by both Houses considerable delay resulted in conference, due to the inability of the conferees to agree on points of difference concerning principally the appointment of executive secretary, definition of navigable waters and limitations for awards on severance damages incurred on recapture of property at the end of the fifty-year license period. The original provision for severance damages as provided in the first House bill was restored by the conferees. Some are of the opinion that the definition of "navigable waters" as given in the conference report will make it impossible for anyone to build a dam for any purpose in any creek or small stream which empties into a navigable river without first obtaining a license from the Federal Power Commission.

Power Factor in Polyphase Circuits

Preliminary Report of Special Joint Committee

THE subject of power factor in polyphase circuits has been the center of increasing discussion in recent years. No agreement has yet been reached upon a definition of the term as applied to polyphase circuits, nor even upon the underlying purpose which a definition should serve to express. In the absence of a practical commercial incentive to a universally accepted understanding as to the purpose and use of the term, little progress has been made toward such an understanding.

There has been no practical incentive for the reason that, until recent years, most polyphase loads were approximately balanced, while the differences between various possible definitions of power factor become of importance only in unbalanced loads, so that no refinement of definition has been needed. At present, however, there are increasingly important developments in types of industrial power loads which are attended by unbalanced conditions between the phases, unbalanced as to amount of loads and as to phase relations between current and voltage. In such cases the numerical value of power factor may vary widely with different definitions.

The increasing commercial importance of this character of load and the growing tendency toward such refinements in power contracts and rates as will reflect accurately the various elements entering into cost of service, have combined to render this power factor problem a matter of immediate and urgent practical importance.

In recognition of the importance of this need, the American Institute of Electrical Engineers, acting through its Standards Committee, and the National Electric Light Association, acting through its Technical Section, have united in the formation of a Committee to be known as the Special Joint Committee on Determination of Power Factor in Polyphase Circuits.

It was decided that this joint Committee should place the results of its labor before the parent organizations by which it had been appointed, namely, the Standards Committee of the A. I. E. E. and the Technical Section of the N. E. L. A. in a form which should indicate the conclusion already reached by the Committee but which would permit of further consideration and discussion by the two parent bodies before a definite solution is reached.

Two definitions covering two different forms of power factor in polyphase circuits were arrived at, together with some suggestions as to proper qualifying terms to apply to each definition. These definitions are as follows:

Definition 1. Power factor in a polyphase circuit is the ratio of the total watts to the (arithmetical) sum of the volt-amperes in the several phases, each measured to a non-inductive neutral point. This definition may be otherwise expressed as the weighted mean of the individual power factor in the phases (weighted according to the volt-amperes in each phase.)

Definition 2. Power factor in a polyphase circuit is the ratio of the total watts to the vector sum of the volt-amperes in the several phases.

A bibliography prepared by Dr. P. G. Agnew and Professor A. E. Kennelly is given as Appendix II to the report. Abstracts and translations of the work of the Italian, Gino Campos and of the German, Dr. F. Niethammer, have been prepared by Mr. W. H. Pratt and are attached to the report as Appendix III. These papers are of basic importance in considering the subject of polyphase power factor.

Polyphase Power Factor

BY F. C. HOLTZ

Chief Engineer, Sangamo Electric Co.

IN a single-phase circuit the various factors relating to power and energy are very clearly defined. For example, power is defined as the rate of energy transfer; apparent power is defined as the product of the r. m. s. value of voltage across the circuit by the value of the current in the circuit.

An interesting development is to take the mathematical expressions which give proper interpretation to the single-phase problem and extend the investigation to include the three-phase problem.

In the single-phase problem we arrive at an expression for power in the form $P o = A + j B$ in which A is the true power and B is the reactive power or volt amperes. The apparent power is given by $\sqrt{A^2 + B^2}$ while the power factor is $\frac{A}{\sqrt{A^2 + B^2}}$ and the reactive factor is $\frac{B}{\sqrt{A^2 + B^2}}$.

Upon applying the same ideas to the investigation of the three-phase problem it develops that there is a one to one correspondence between the two. Power being expressed in the form $P \phi = A \phi j + B \phi$ where $A \phi$ is again the true power as measured by any of the well known methods and $B \phi$ is the reactive power or

Abstracts of papers to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

volt amperes in the three phase circuit. We also have that the apparent power is $\sqrt{A^2\phi + B^2\phi}$ while $\frac{A\phi}{\sqrt{A^2\phi + B^2\phi}}$ and $\frac{B\phi}{\sqrt{A^2\phi + B^2\phi}}$ are the three phase power factors and reactive factors respectively.

It is shown that the power factor as defined by the above is in accord with the vector definition for power factor as outlined by the committee. The absurdities which result from using the arithmetic definition of power factor are shown.

The problem of measuring the apparent energy in the three-phase circuit under the vector definition involves the necessity of integrating a quantity of the form $\sqrt{A^2\phi + B^2\phi}\,dt$. An instrument to do this must therefore integrate the square root of the sum of two squares. Such an instrument may be quite easily constructed.

For example referring to Fig. 7, we may assume two vector quantities in the same plane starting at a given instant $t\,o$ from some point O, one moving in the direction of $O\,Q$ and with a velocity which is a function of the time T, the other moving at an angle from $O\,Q$ and in the direction $O\,P$ with a velocity which is also a function of the time. At a time $\delta\,t$ after starting we have the two values $O\,P$ and $O\,Q$ and the difference $Q\,P$ which represents the approximate integral of the two vectors over the time $\delta\,t$. Suppose further that we construct two mechanically moving rods arranged at the proper angle to each other. To the point P is attached a flexible cord which passes over the point Q to a small drum located somewhere on the rod $O\,Q$ or its equivalent. Attached to the small drum is counter or other device which records accurately the length of $Q\,P$ removed from the drum and through auxiliary devices the points P and Q are returned to zero at definite intervals. It is so arranged that the mechanism of the drum shall record the sum of the lengths $Q\,P$.

$$\sum_{1}^{m} P\,Q = P_1\,Q_1 + P_2\,Q_2 + \ldots\ldots + P_n\,Q_n$$

where $P_1\,Q_1$ represents the value of $P\,Q$ during the first interval, $P_2\,Q_2$ represents that during the second interval of time etc. From this it is quite apparent that $\sum_{1}^{m} P\,Q$ will represent as close an approximation as is desired to the true integral of the two vector quantities. This can be regulated by regulating the time interval of reset $d\,t$.

The integration of the volt-ampere-hours in an alternating-current circuit is a specific case requiring the application of the above. In this case the vectors are located at right angles to each other and the mechanical device is operated directly from the contacts of two watthour meters.

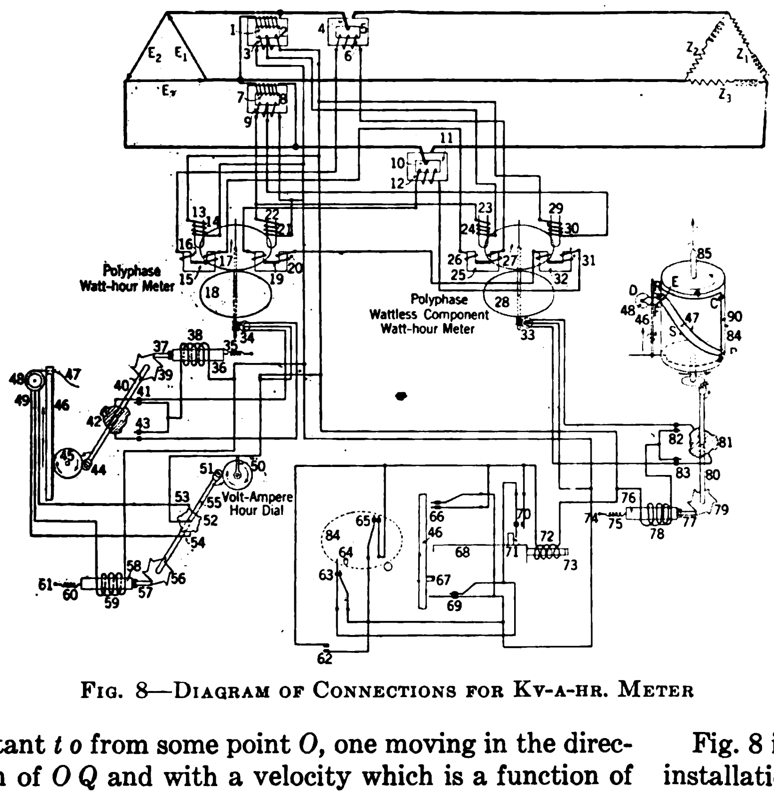

Fig. 8—Diagram of Connections for Kv-a-hr. Meter

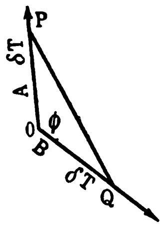

Fig. 7

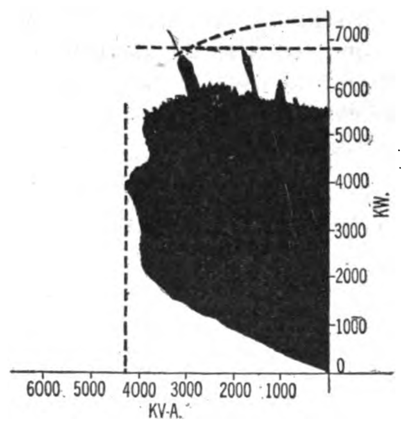

Fig. 9

Fig. 8 illustrates the case of a three-phase three wire installation.

Here the two meters are shown connected to the instrument transformers. One is so connected as to register the watthours while the other integrates the reactive component. The contact devices are represented by 34 and 35. To the right of the figure is shown the assembled mechanism, the other part of the drawing is used to represent the electrical circuits involved. Instead of using two rods operating at right angles to each other one is replaced by a rotatable cylinder in order to economize on space and increase the accuracy of the instrument. One of the moving elements consists of a drum 48 attached to a vertical

rack 46 and so arranged that with each contact of the wattless component meter the drum is rotated through a definite angle. The small drum 48 carries a silk cord 47 which passes through an eye F and is attached to the drum 84 at P. It is so arranged that with the drum 48 attached to rack 46 and drum 84 in their zero position the points P and F coincide.

Let us assume now that both meters are under rotation. With each contact at 34 the vertical rack 46 is stepped up a definite amount and with each contact at 35 the drum 84 is rotated through a definite angle. After a given time interval, say 10 minutes the positions of rack 46 and drum 84 are as shown. The cord removed from the drum 48 will be the length between P and F. Under conditions of design the rotation of 84 is proportional to $\int_{T_1}^{T_2} W\,dt$ and the height of F above its zero position is $\int_{T_1}^{T_2} R\,dt$ so that $\overline{PF} = \sqrt{W^2 + R^2}\,dt$ which is the apparent energy during the time interval. At definite time intervals contact 62 is closed and through operation of solenoid 72 both rack 46 and drum 84 are returned to their zero position. This operation is continued so long as the system is in operation.

Drum 48 carries a three-lead contact 49 which is used to operate a distant dial mechanism so calibrated as to read directly in kv-a-hr.

In addition to the cord 47 a card 90 is mounted on the drum 84 and to the rack 46 is attached a stylus R'. With each interval of operation a new line is marked on the card 90 and length of which will determine the maximum demand in kv-a.

Fig. 9 is representative of about how one of these cords would appear after a month's operation. The date taken from this chart is as follows:

1. Maximum demand in kw. 6800.
2. Maximum demand in reactive component 4300 kv-a.
3. Maximum demand in kv-a. 7400.
4. P. F. at maximum demand $\frac{6700}{7400}$ = 90.6 per cent

Measurement of Power Factor on Unbalanced Polyphase Circuits

BY R. D. EVANS

General Engineer, Westinghouse Electric & Mfg. Co.

THE object of this paper is two-fold, first, to give a scientific definition of power factor, and, second, to describe devices for measuring power factor and devices for measuring unbalance of a polyphase system.

On the Definition of Power Factor

Power factor is a term which describes the flow of energy in an alternating current circuit and which expresses a relation between the amount of energy converted into heat or mechanical work, and the amount of energy periodically absorbed and discharged in the circuit. Power factor is not the simplest factor related to true power and reactive power, but it is a convenient factor, as it expresses a ratio between the amount of power actually delivered in a circuit, to the amount of power which might be delivered without exceeding the same heating.

Power factor may be defined as the ratio of true power to the square root of the sum of the squares of the true power and the reactive power.

$$\text{P. F.} = \frac{P}{\sqrt{P^2 + Q^2}}$$

In the above expression, P is the algebraic sum of the watts, and Q is the algebraic sum of the reactive watts in all of the component parts of the circuit.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

It is to be noted that the definition of power factor, from the standpoint of the flow of energy, is complete, and is independent of the presence of harmonics, plurality of phases, or unbalance, that is, the definition requires no extension to take care of these cases. On the other hand, the definition of power factor, from the standpoint of phase difference, or the ratio of watts to volt amperes, requires modification to take care of the complication resulting from the presence of harmonics, plurality of phases, or unbalance.

Devices for Measuring Unbalance of a Polyphase System

Any system of unbalanced voltages may be resolved into two or more balanced systems of voltages of different phase sequences, each of which may be measured by stationary instruments. The meter for measuring positive or negative sequence voltage, on a three phase, three-wire system, consists of a voltmeter with two windings and two external series impedances of different power factors. Another form of this instrument is described, and this consists of a standard voltmeter, two external impedances, and two standard potential transformers.

In a similar manner, the positive and negative sequence currents may be measured. Such an instrument is described and consists of a standard ammeter, two external impedances, and two standard current transformers.

The theory of these meters is explained from differ-

ent viewpoints. One explanation is based on a physical interpretation of the mathematical solution. Another explanation is based on showing that the voltages of one sequence causes the meter to read and the voltages of the other sequence do not, and, therefore, in the presence of two sequences, the meter measures a quantity proportional to one of them. A third explanation is based on the idea of a network in connection with a meter element. From this point of view, it is only necessary to provide a network that permits only current of the desired sequence to flow in the branch in which the meter is connected.

Power Factor Meters for Unbalanced Circuits

Having separated out the positive and negative sequence voltages and currents, the next step is to combine them for measuring power, reactive power or reactive volt-amperes and power factor. Standard instruments supplied with positive sequence voltage and current, measure positive sequence watts, positive sequence reactive watts or reactive volt-amperes, or positive sequence power factor. A meter is described which measures positive sequence power factor.

In an unbalanced system, as many separate meter elements are required to measure the total power, total reactive power, or the total power factor, as there are sequences of power present. A meter is described which measures total power factor on a three-phase, three-wire system. This meter consists of two single-phase power factor meter elements, mounted on a common shaft, and one element supplied with positive sequence voltage and current, and the other element with negative sequence voltage and current.

Conclusion

Power factor, reactive factor, power and reactive power, must be defined so that their mutual relations are shown, and so that they correspond to the physical facts. A scientific or exact definition of power factor must first be formulated, and then on this foundation, a practical definition for use in rate making may be built.

The exact definition of power factor should be based on the flow of energy. Power factor is the ratio of true power to the square root of the sum of the squares of true power and reactive power.

It must be recognized that power and power factor do not completely describe the flow of energy, and that the use of some unbalance factor is necessary. Standard instruments may be employed to measure the unbalance of a system.

Power factor and unbalance are independent quantities and should be charged for separately.

Polyphase Power Factor

BY H. L. WALLAU

Electrical Engineer, Cleveland Elec. Ill. Co.

THE Special Joint Committee on Determination of Power Factor in Polyphase Circuits has formulated two definitions for this factor.

As technicians will doubtless all agree that Definition 2 which is mathematically accurate must be adopted to represent that quantity which today is referred to as power factor when applied to single-phase or to *balanced* polyphase circuits.

As commercial engineers we must recognize that Definition 1 has a broad field of usefulness, when applied to unbalanced circuits.

The central station industry today is compelled to take on single-phase loads of considerable magnitude.

These loads consist of welders of very poor power factor, (20 to 40 per cent) single-phase arc furnaces of relatively better (35 to 70 per cent) but nevertheless poor power factor, and in some cases single-phase railway loads also of poor characteristics, together with both inductive and non-inductive loads of other kinds.

If it were commercially practicable to compel the consumer to install phase-balancers or motor generator sets in connection with such loads, the inherent difficulties due to out-of-balance loads would be done away with. Obviously, this is impossible. As a result the companies must operate under certain disadvantages, with these loads connected to their systems, such as reduced effective capacity of three-phase circuits, increased heating in cables, etc. In addition, if the out-of-balance becomes of sufficient magnitude at the power plant, generator troubles will result.

Increased costs of supply result therefrom. Either the rates in our industrial schedules must reflect these added costs and proportion them over all consumers alike, or some means of penalizing the consumers causing the added burden must be incorporated therein.

This means is conveniently provided by a power factor clause. If, however, a strictly technical definition is adopted for incorporation into rate schedule, it takes no account of the effect of unbalanced currents yielding as it does a higher power factor than that obtained by the proposed commercial Definition 1.

To care for this condition a new factor, termed balance factor, has been suggested. After we have defined this factor in a manner satisfactory to all, what practical means will we have of obtaining it, and if obtained

---

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

how shall we apply it? Its commercial use in rate schedules in addition to a power factor clause introduces a new stumbling block over which the prospective customer must be safely lifted. For that reason for commercial work Definition 1 is preferable.

This view is that of an engineer of a supply company interested in obtaining a definition that can be used in contracts for the sale of power, and is relatively simple and easily understood.

Definition 1 takes into account the maximum wattage obtainable based on the currents and voltages existing, and the ratio of this quantity to the actual watts measured is the power factor which, the author believes, should preferably be standardized for commercial work.

The name of the Committee suggests the next essential step. Not only must we define polyphase power factor, but we must determine a suitable, reliable, inexpensive and uniform method of measuring the quantity defined.

To date neither definitions nor methods are standard with us. There is a real need for both.

Power Factor in Polyphase Systems

BY FRANCIS B. SILSBEE

Associate Physicist, U. S. Bureau of Standards

THE use of a number of different definitions of "power factor" as applied to unbalance polyphase system has led to much confusion. The present paper points out the mutual relations of a number of possible definitions and their relative merits for specific types of circuits.

Power factor has two distinct applications for economic and technical purposes respectively, and the selection of the single property which any one definition of power factor can determine must be considered from two distinct points of view. The economic importance arises from the fact that it is more expensive to supply a given power to an actual load in which the currents are not in phase with the voltages or in which the currents in the several phases are not equal in magnitude than it is to supply a standard load in which some or all of these adverse conditions are absent. Three distinct types of standard load have been tacitly assumed in the development of the several definitions now in use: (A) a balanced load in which both the currents and the voltages are symmetrical and in phase; (B) a load in which the currents have the same magnitudes as in the actual load but in which the current system as a whole has been shifted in phase with respect to the voltage system, so as to make the total power a maximum (i. e., such a shift as would be produced by a symmetrical polyphase synchronous condenser); and (C) a load in which each current has the same magnitude as in the actual load that has been individually shifted into phase with its corresponding voltage.

There are also two distinct items of cost which must be considered (1) the fixed charges on the additional generator and line capacity required to supply the actual low power factor load and (2) the cost of the additional power lost in the generating circuits. The ratio of the actual power to the power which might be supplied to a standard load either (1) by the same generator capacity or (2) with the same power loss, may be taken as the logical economic definition of power factor.

For a standard load of type A and a symmetrical polyphase generator the most logical power factor is the ratio of the watts to the "effective volt-amperes", this latter quantity being defined as the product of the square root of the sum of the squares of the live currents multiplied by the square root of the sum of the squares of the voltages to neutral. For a standard load of type (B) the "vector power factor" (Def. 2 of the special joint committee) and for a standard load of type C the "arithmetical power factor" (Def. 1) are most logical.

For technical purposes it is highly desirable to separate the effects of phase displacement, unbalance and wave form since the causes and remedies for each are quite distinct. This can readily be accomplished by defining one or more additional quantities so that one quantity (such for example as "vector power factor") indicates the phase displacement as distinct from unbalance; and a second quantity (such as balance factor) shows the symmetry of the loading as distinct from any general phase shift. The first quantity thus shows the extent to which conditions might be improved by the installation of synchronous condensers, while the second indicates the possible gain from phase converters or by rearrangement of the load.

For the first quantity the vector power factor is undoubtedly most useful. It is independent of the potential of the neutal point to which the voltages are measured, and also it may be obtained by adding the real and reactive components of the individual branches of any network. It is directly related to the mean magneto and electrostatic energies of the system and to the amount of excitation required.

"Balance factor" is useful principally to indicate (1) the pulsations in instantaneous power and (2) the increase in heating of the generators which results

---

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

from any unbalance. If the voltages are symmetrical these two properties depend upon the same combination of variables and may both be covered by a single definition. If, however, the voltages are not symmetrical this relation no longer holds and a uniform flow of power may result from a very unsymmetrical system of currents and voltages which would produce considerably increased heating. A convenient definition for the heating aspect is "effective balance factor" equals $\frac{\text{vector volt-amperes}}{\text{effective volt-amperes}}$, since this leads to the relation: Effective balance factor $\times$ vector power factor = effective power factor; and serves to reconcile the economic requirement for a single factor based on heating effects with the technical requirements for a separation of phase shift and unbalance.

In the complete paper the various possible "volt-amperes", pulsation in power and related quantities are expressed mathematically so that their interrelations may be noted, and a number of numerical examples are worked out. The generalization of the definitions to include cases where the wave forms are not sinusoidal, and the instrumental methods for measuring the various quantities involved, are also discussed.

Polyphase Power Representation by Means of Symmetrical Coordinates

BY C. L. FORTESCUE

Engineering Dept. Westinghouse Electric & Mfg. Co.

THIS paper is a more complete presentation of the subject of power representation by means of symmetrical coordinates, which was briefly outlined in the author's paper on Symmetrical Co-ordinates presented at the 30th Annual Convention, 1918.

A short treatment of the subject of single-phase power is given, and it is shown that the product $\check{E}\,\check{I} = P + j\,Q$, where P is the true power and Q the reactive power, completely specifies all characteristics of the power when the phase of the e. m. f., $\check{E}$ is given. The phase of the double-frequency component $P_H + j\,Q_H$ is as much in advance of $\check{E}$ as $\check{E}$ is in advance of $P + j\,Q$.

The question of single-phase power measurements is touched on. It is shown that the wattmeter is normally a reactive power meter. It is only a true power meter when the current in the voltage coil is constrained to be proportional to, and in phase with, the impressed e. m. f. The watthour meter measures energy by reason of the fact that the current in the voltage coil is constrained to be in quadrature to the impressed e. m. f. If it were constrained to be in phase with the impressed e. m. f., which could be just as easily accomplished, this instrument would integrate the mean reactive power.

It is shown that four measurements are required to completely determine a single-phase load mathematically; the two complex variables $\check{E}$ and $\check{I}$, furnish all the necessary data.

In practical measurements, it is usual to specify the impressed e. m. f., the kilovolt-amperes, and the power factor; the true phase of the impressed e. m. f. being arbitrary.

A symmetrical polyphase system requires for its complete determination four quantities which are usually

1. The e. m. f. of one phase.
2. Its phase angle.
3. The current in one phase.
4. Its phase angle.

The particular phase under consideration may be termed the "principal phase."

Since an unbalanced n-phase system of currents and e. m. fs. may be resolved at most into n symmetrical systems of currents and e. m. fs., the maximum number of measurements required to completely define such a system is $4\,n$ and the minimum number may be from 4 up to $4\,n$ depending upon the nature of the dissymmetry.

The quantities expressed in symmetrical co-ordinates required to completely define a three-phase, four tone system are:

$S^\circ\,\check{E}_{A0}$, $S^1 E_{A1}$, $S^2\,\check{E}_{A2}$ the symmetrical components of e. m. f. and $S^\circ\,\check{I}_{A0}$, $S^1\,\check{I}_{A1}$ and $S^2\,\check{I}_{A2}$ the symmetrical components of current. The sequence symbols have the following significance. The S° system consists of three equal vectors of the same phase. The S^1 or positive phase sequence system consists of three equal vectors each of which lags $\frac{2\,\pi}{3}$ behind the preceding vector when taken in their alphabetic order. The S^2 or negative phase sequence system consists of three equal vectors each of which leads the preceding vector by $\frac{2\,\pi}{3}$ when taken in alphabetic order. These sequence symbols have the property of combining by the law of indices when products of two sequences are formed.

Instantaneous symmetrical systems are formed from the symbolic systems in exactly the same manner as for single-phase, and by following the same procedure

---

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

for obtaining the power products as in the treatment of single-phase system, we obtain similar expressions as in single-phase, and the zero frequency system of power vectors obtained completely specify the whole system of power vectors.

In an unbalanced three-phase, three-wire system there are three systems of zero frequency power vectors. The S^0 system consists of the true and reactive power due to the positive and negative sequence currents and e. m. f., and S^1 and S^2 systems whose instantaneous value is zero; they represent interchange of power among the phases, and therefore, are a measure of the degree of unbalance. It is shown that if the true and reactive power of each phase of a system are given and true power is taken as datum and the vectors so formed are resolved by the method of symmetrical co-ordinates, the systems of power vectors deduced above are obtained.

Three-phase power measurements are discussed: It is shown that in all the usual power measurements, the true and reactive power due to positive phase sequence and negative phase sequence appear as entities and may be separated. They are therefore not mathematical fictions but actual concrete quantities.

All true and reactive power measurements by symmetrical co-ordinates methods may be accomplished by a single movement. A comparison is made between the present method of measurements and those following the principle of symmetrical co-ordinates. The same number of instruments are required in each case but the symmetrical co-ordinate method completely determines all necessary factors without computation.

A method of graphically obtaining the complete solution of a system when measurements are given is shown.

The author holds that it is of the highest importance that definitions of the fundamental quantities and factors concerned with the measurements of e. m. f. current, power and energy be scientifically correct. It is not vitally important in practical work that all definitions shall be adhered to, but it is vitally important that our standard definitions be based on sound scientific principles.

Definition of Power Factor. Power factor shall be determined from measurements of three-phase power by means of two or more wattmeters connected in the usual manner and from reactive power measured by a reactive power meter with the same connections as those used in measuring the true power. If P be the true power and Q the reactive power

$$\text{Power factor} = \frac{P}{\sqrt{P^2 + Q^2}}$$

The positive phase sequence power factor and negative phase sequence power factor are obtained in a similar manner.

Definition of Unbalance Factor. The ratio of one unit of the negative phase sequence component of a quantity to the corresponding unit of its positive phase sequence component is defined as the *unbalance factor* of the quantity under consideration. Usually the ratio of the magnitudes only need be considered.

Conclusion. The definitions proposed are easily measured and completely and uniquely determine all the quantities it is necessary to know in order to make proper charges for energy.

Polyphase Power Factors and Unbalanced Loads

BY PHILIP TORCHIO

Chief Electrical Engineer, N. Y. Edison Co.

DEFINITION No. 1 in the Committee's report gives a numerical relation applicable to any polyphase circuit, which is also intended to give a measure, as a general average, of the greater outlay of apparatus and plant that the supply of unbalanced loads entails. Without attempting to state whether such numerical averaging gives a fair compromise measure of the added economical burden of carrying unbalanced loads, it is important that we definitely and clearly describe the results of the applications of this definition No. 1. For this purpose I submit in the table herewith comparative results of the amount of capacity of electrical equipment required for generating and transmitting a unit amount of power under different conditions of unbalancing, all giving the same average value of power factor definition No. 1:

	Capacity of electrical equipment required for generating and transmitting 1000 kw. of		
	Balanced load	Unbalanced load	Unbalanced load (Single phase)
Power factor by definition No. 1 per cent			100–99.5	1000 kv-a.	1100 kv-a.	Not possible
86.6	1150 "	1250 "	1740 kv-a.
75.0	1330 "	1425 "	2000 "
50.0	2000 "	2175 "	3000 "

The above comparison shows that, with apparently the same value of polyphase power factor, the capacity of electrical equipment required for generating and transmitting the same amount of power may vary as much as from 1 to 1½. It is obvious that under such

To be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies can be obtained as soon as available by applying to Institute headquarters.

extreme conditions the cost of service would be quite different in the several cases.

On the other hand, the unbalanced load of one customer may be compensated by the contemporaneous unbalanced loads on other phases of other customers, so that, as a net result, on the supply company's equipment only a fraction of its equipment may be affected by the "apparent" low power factor due to unbalanced loads, this effect being perhaps limited only to the district where the power is distributed, but being balanced and equalized on the transmission line and the generators.

The power rate engineer may, therefore, have greater need of the *"comtemporaneous unbalanced loads and power factors of definition No. 2"* for the individual customer and for the district, than the average power factors of definition No. 1.

In this connection it would seem wise to make reference to the importance of defining the time intervals during which the power factors are to be taken. It will be of particular value to the power rate engineer to have *power factor diagrams* for the twenty-four hours for the customer and district under consideration, rather than the power factor for one minute or fifteen minute period of maximum demand or the average power factor for the twenty-four hours, which will be of small value to him in analyzing the cost of such service. The same comment may be made as to the recording of unbalanced loads.

Power Factor and Unbalance on a Polyphase System

BY CARL J. FECHHEIMER

Designing Engineer, Westinghouse Electric & Mfg. Co.

In a single-phase or balanced polyphase circuit, the two factors which are contributory to power factors less than unity are wave distortion and phase displacement between current and voltage. In the paper the influence of wave shape is not considered, since in most large modern systems the wave form is nearly sinusoidal. The paper covers balanced and unbalanced polyphase systems without neutral current.

Power factor and unbalance are two distinct phenomena; therefore any attempt to formulate a definition which combines them is certain to be meaningless and of very questionable value.

The general case of a polyphase system is treated from the standpoint of two polyphase systems of opposite phase sequence. A proof is given that the usual unbalanced system of currents in machines is physically made up of two balanced systems of opposite phase sequence, thereby showing that the method is more than a mathematical convenience. In Appendix A, a physical proof is given for the fact that in the rotor of a synchronously driven single-phase induction motor or synchronous machine, double frequency polyphase currents are induced which are productive of m. m. f. which is constant in magnitude and rotates at synchronous speed in the opposite directions to the rotor, and this m. m. f., when combined with the alternating m. m. f. due to the stator currents, gives a resultant m. m. f. which is constant in magnitude and revolves at synchronous speed in the same direction as the rotor. In the induction motor the flux is proportional to this latter m. m. f.; in the alternator it is the "armature reaction." Thus, the alternating m. m. f., due to the single-phase stator currents gives rise to two equal and opposite m. m. f., both traveling at synchronous speed but in opposite directions.

In Fig. 2, OA is the m. m. f. of the polyphase double frequency rotor currents, which rotates negatively at synchronous speed. OD is the alternating stator m. m. f. which is fixed in position; and OC is the resultant of the two, which rotates in a positive direction at synchronous speed. The same final results would have been obtained had OD been taken as the resultant of OC, of positive rotation, and OB, equal and opposite

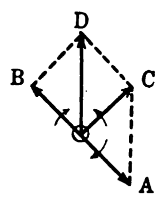

FIG. 2

Time angle = 30 deg.

Rotor m. m. f. = 1, shifted clockwise 30 deg.
Resultant = 1, shifted counter-clockwise 30 deg.

to OA, and of negative rotation. Then the alternating m. m. f., OD, is the resultant of two equal m. m. fs, constant in magnitude, both rotating synchronously in opposite directions. One m. m. f. is productive of flux (or armature reaction); the other is that which is needed to neutralize the rotor magnetizing or damper currents.

In a polyphase machine, a rotating m. m. f. is produced by a polyphase system of currents, and therefore the two oppositely rotating m. m. f. systems in Fig. 2, may each be so represented, as in Figs. 3 and 4 where four-phase systems are shown. These combined give the single-phase system of Fig. 5.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

Two equal three-phase systems of opposite phase sequence may be similarly combined to give a single-phase system. If the balanced negative sequence system is decreased in magnitude, or changed in phase relation to the positive sequence system the resultant is an unbalanced polyphase system. Conversely, the unbalance polyphase system may be broken into two

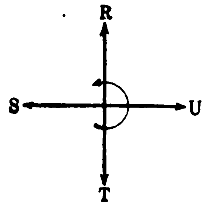

FIG. 3

Time angle = 45 deg.
Stator m. m. f. = 0.707 × 2 = 1.414
Rotor m. m. f. = 1, shifted clockwise 45 deg.
Resultant m. m. f. = 1, shifted counter-clockwise 45 deg.

balanced polyphase systems of opposite phase sequence; in appendices B and C are given illustrative methods, graphical and analytical, for doing this. This method of solving the unbalanced system is unique in that there *is but one solution* for any given system; on the other hand, the method of breaking into a balanced polyphase and superimposed single-phase systems permits of an infinite number of solutions.

The same general law for losses that applies to the

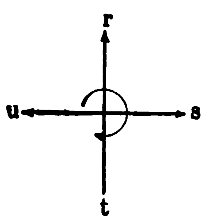

FIG. 4

Time angle = 60 deg.
Stator m. m. f. = 0.5 × 2 = 1
Rotor m. m. f. = 1, shifted clockwise 60 deg.
Resultant = 1, shifted counter-clockwise 60 deg.

in-phase and quadrature components of current, and the combination of currents of different frequencies, namely, the "sum of the squares" law, applies also when the unbalanced system of currents is broken into its constituent positive and negative sequence systems; this is proved in appendix D.

The deleterious effects of a relatively small unbalance in voltage upon synchronous and induction machinery due to a not inconsiderable unbalance in currents are discussed; especially is this so with synchronous converters. The negative sequence currents in such apparatus, due to unbalance in line voltage, tend to correct the unbalance of the system, and these negative sequence currents are in consequence displaced 180 deg. from those negative sequence currents which produce the unbalance.

In any case, the true power in the polyphase system is the sum of the power in the positive and that in the negative sequence systems; similarly for reactive power the power factor is the ratio of the true power to the square root of the sum of the squares of the true and reactive powers. In general, the negative sequence voltage and power are small compared with the positive, so that the following definitions are proposed:

"The power factor is the ratio of the true watts to the volt-amperes in the balanced positive sequence systems of volts and amperes."

"The unbalance factor is the ratio of the negative sequence amperes to the positive sequence amperes."

Thus, the proposed definition for power factor fits in with the usual idea: it is the cosine of the angle between current and voltage in the positive sequence system.

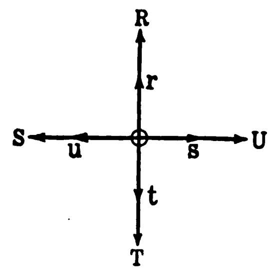

FIG. 5

Time angle = 90 deg.
Stator m. m. f. = 0
Rotor m. m. f. = 1, shifted clockwise 90 deg.
Resultant m. m. f. = 1, shifted counter-clockwise 90 deg.

The definition for unbalance disregards unbalance in voltage. Had it been expressed as "the ratio of the negative sequence volt-amperes to the positive sequence volt-amperes," it would have been undesirable because the negative sequence voltage is very largely dependent upon the synchronous and induction apparatus on the system, and consequently volt-amperes are no measure of the degree to which the system is unbalanced by a given customer.

The method of breaking the unbalanced systems into their constituent systems can be readily used in measurement, as is covered in another paper by Mr. R. D. Evans.

Parallel cases in which physical quantities are separated into their component parts are given. The most striking example is that of a distorted wave which is generated in the alternator due to the non-sinusoidal distribution of flux in the air gap. This wave is looked upon by all engineers as composed of one of fundamental frequency with superimposed waves of higher frequency. Physical evidence is also given by an oscillogram taken on the secondary of an induction motor when slightly unbalanced voltages were applied to the primary.

Eddy Current Losses in Armature Conductors

BY R. E. GILMAN

Westinghouse Electric & Mfg. Co.

THIS paper covers the development of formulas and curve data which permit of the ready calculation of the eddy current losses in armature conductors.

Previous published information on this subject has covered solid or infinitely laminated conductors and then only for the case where all the conductor currents in the same slot are in phase.

This paper first shows the development of the general formula for the loss ratio in a conductor carrying current, when located in any position in a slot with reference to other conductors, which carry currents of the same or different phase.

The loss ratio referred to is the ratio of actual alternating current loss plus the effect of eddy currents to the loss in the conductor carrying the same effective value of direct current.

The paper is then extended to cover the calculation of the loss ratio for the majority of commercial windings in common use. Present day windings consist of one or two coil sides per slot. The final formulas give the equivalent loss ratio for such a group of conductors as will be included in one coil side or as are contained in one common insulating cell from ground. These formulas cover the effect of different combinations of strand groupings as well as the effect of changing the number and dimensions of the strands. In addition, the effect of length of end windings and the use of short cord windings is given.

A series of tests results are given where various combinations of strands and groupings were used, and the loss ratio from these results is compared to the calculations from the formulas.

Temperatures in Large Alternating Current Generators

BY W. J. FOSTER

Engineering Dept. General Electric Co.

THE general public undoubtedly thinks of the size of a machine in terms of its physical dimensions or the work it can do. To the engineer, largeness involves the difficulties inherent in the design and construction. To him, a 5000 kv-a. generator at 3600 revs. per min. is large, while a 20,000 kv-a. generator at 100 revolutions is not large if considered strictly with reference to the temperature problem.

The two principal factors in the temperature problem are, first, the total losses or the amount of energy in the form of heat to be removed and, second, the means that can be provided for dissipating the heat. In a rotating electric machine three sources of heat are always involved: first, hysteretic losses in the magnetic material, second, the resistance to flow of current in the windings and, third, the frictional losses in bearings and windage.

In considering the temperature problem, the first and most fundamental consideration is the relation of the space occupied by the object to the total heat losses to be dissipated. A 20,000 kv-a., 100 rev. per min. machine compared with one of the same output at 1800 rev. per min., has its losses generated in a space eight times as great in terms of cubical space occupied, or approximately two times in the projected area occupied. We may well think of the temperature problem in terms of heat losses to space occupied. Below a certain value of this constant it is absurd to use ventilation housings, no matter how great the rating of the machine, as such housings have the effect of preventing the natural means of heat dissipation, viz., convection and radiation, and ventilation housings in such cases result in higher temperatures, unless forced draft is provided, which results in a decrease in the efficiency of the unit and can be justified only on the score of reduction of noise or some similar reason.

The author calls attention to the advantages resulting from drawing the air into the two ends of a generator directly from the dynamo room and piping it away, in connection with hydraulic units.

Water is an ideal agent for cooling purposes by reason of its high capacity for heat, but it is difficult and almost impossible to use it for removing the heat generated in the rotating element of a generator. There are objections to its use in the stationary element, such as, danger from leaks developing in the pipes and condensation on surface of pipes.

Curve sheets are given to show the importance of selecting a diameter that involves a fairly high peripheral speed. The higher the peripheral velocity the better the efficiency until the point is reached where the higher windage losses more than offset the reduced iron and copper losses.

Curves are given to show the distribution axially of

Abstracts of papers to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete papers can be obtained as soon as available by applying to Institute headquarters.

the cooling air in stator cores as related to the sectionalizing of core and the internal temperatures of the armature coils as affected by different sectionalization.

Curves are also given to show the rate of temperature rise and the time required to reach constant temperatures in the various parts of generators of the salient pole type and also of the cylindrical rotor type.

Under the topic "High vs. Low Temperature Generators" the author advocates conservatism in temperatures for both classes of generators—the so-called low and high temperature machines for which the Institute has standardized Class A and Class B insulations. He claims longer life and better efficiencies as a rule, for generators that have low temperatures.

Classification of Large Steam Turbo Generator Failures

BY PHILIP TORCHIO

The writer classifies fifty-five generator failures of which he has a record or report. The machines are installed in different parts of this country. Their capacities range from 5000 to 30,000, the smaller size dating back from twelve to sixteen years, and the larger being of more recent manufacture.

The failures, several occurring on the same unit, are summarized as follows:

Armature failures due to:		
Mechanical damages	3	
Heating of windings	17	
Heating of iron	2	
Loose laminations	1	
Moisture in cooling air	3	
Corona shield breaking	2	
Heating at end turn clamping	1	
Causes undiscovered	2	33
Field failures due to:		
Open circuited connections	3	
Grounding	7	
Grounding caused by bus short circuit	4	
Loosening of damper windings	2	16
Armature and field failures due to:		
Moisture	1	
Undiscovered	3	4
Terminal failures due to:		
Moisture	2	2

To avoid similar troubles, designing engineers should use insulating materials of proved dependability, maintain low copper temperatures by proper subdivision of copper and transposition of strands in windings and provide liberal ventilation throughout the machine. The operating copper temperatures should be limited at or closely to 100 deg. cent. Too great range of operating temperatures is bound to cause generator failures. Mica insulation in hydroelectric generators operated at steady load will last indefinitely at high temperatures, while, under similar conditions, mica insulation in steam turbo generators operated intermittently will fail.

The test voltage for windings should be raised to three times full voltage plus 1000.

Mica and asbestos tape insulation for fields is more dependable than fibrous insulation. Solid forged fields are preferable to laminated field structures or even built-up plate structures.

Users must exercise great care in the supply of cooling air to prevent moisture or condensation depositing on the windings.

Ventilation and Temperature Problems in Turbo Generators

BY B. G. LAMME

Chief Engineer, Westinghouse Elec. & Mfg. Co.

THERE are four effective materials concerned in turbo-generator operation, namely, the iron for magnetic purposes, the copper in the windings, the insulation encasing the windings and the ventilating air. As the iron and copper have long since been carried to their practical limits, it follows that the major part of recent developments has been in the insulation and the ventilation. In fact, it may be said that the present commercial insulations for such apparatus have been utilized fairly well up to their limits for some years. Therefore, it follows that the more recent growth in large turbo-generator work has been largely along the lines of improved methods of heat dissipation, that is, of improved air circulation.

Broadly speaking, there is but one method of turbo-generator ventilation in use at the present time, namely, forcing large volumes of air through the machine at a high velocity. The systems of ventilation used may be classified as radial and axial. Both methods are used, to a certain extent, in all practical machines at the present time. These two methods of ventilation are described briefly and problems and difficulties relating to each are discussed.

Abstracts of papers to be presented at the A.I.E.E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete papers can be obtained as soon as available by applying to Institute headquarters.

The above is followed by a discussion of the problems of heat flow in connection with the copper, iron and insulating parts, indicating, in a general way, where the principal temperature drops occur. This is followed by a general discussion of copper, iron and air friction losses and a rough indication is given as to the enormous volumes of cooling air required by such machinery.

Temperature determination is next taken up, with a short discussion of the methods approximating the highest temperature, by means of embedded detectors.

The paper is intended to be educational in the sense that it points out what the actual turbo-generator problems are, in so far as they concern turbo ventilation. It does not attempt to go into the quantitative solution of such problems.

Some Practical Experience with Embedded Temperature Detectors

BY F. D. NEWBURY and C. J. FECHHEIMER

Engineering Dept. Westinghouse Electric & Mfg. Co.

ENGINEERS are interested in the maximum armature coil temperatures and in the average temperature of the embedded portion of the coil. Only the former are discussed at length in the paper, and test data are submitted to bear out the statements; in general the test data include temperature measurements on the bare copper.

There may be very material errors due to improper installation of the detectors; and even if properly installed between coil sides, the detector does not read the maximum copper temperature. The principal reasons for the latter are that there is a flow of heat from the adjacent sides of the copper in the upper and lower coils to the slot sides, and that there is a difference in temperature between the upper and lower coils. The heat flow to the slot sides is augmented by the fact that the longitudinal thermal conductivity of built-up insulation is from three to ten times the transverse conductivity. Even with an isotropic medium the flow of heat to the slot sides lowers the detector reading. The relative side flow is increased with increase in distance between copper conductors in upper and lower coil sides.

The difference in temperature between the copper in the two coils is due principally to difference in eddy current loss, arising from the cyclic change of leakage flux. The eddy loss in the top coil is lowered if the throw of the coils in the particular slot in which the detector is placed is such as to increase the phase angle between the currents in the two coils, as is proved by test data.

The principal sources of errors pointed out in the paper, arising from improper installation of detectors between coil sides, are due to the wrapping of the upper and lower coils individually, thereby permitting cool air at the vents to lower the detector temperature, and the use of wide detectors. Test data on a 12,000-kv-a alternator and on a model of an armature with thermocouples on the bare copper, as well as between coils, with the one and two slot cell arrangements are submitted; and in addition, in the case of the model, data with wide and narrow resistance exploring coils are given. In order to show that the air currents which lower the detector readings did not lower the internal temperatures, data are also incorporated, in the case of the model, with packing between the coils. The data confirm the statements in regard to errors. It further seems from the data that there is a greater difference between the maximum and minimum readings with detectors between coils exposed to the cooling air than with detectors similarly placed but protected from the air, and the difference is smallest with detectors on the bare copper.

Detectors at the bottom of a slot in the 12,000-kv-a. alternator, and at the bottom of a slot and under wedge in a 3750-kv-a. turbo generator showed (in conjunction with readings on the bare copper) that detectors so placed cannot read the copper temperature, nor in any way give an indication of the thermal drop through the insulation. The detector reads the temperature of that part of the iron or wedge with which it is in contact.

Tests show that the copper at the top of the upper coil is not necessarily at the highest temperature, because the wedge is usually cooler than the iron. If the maximum copper temperature is sought, detectors should be placed at various depths in the upper coil.

The paper concludes with a summary, conclusions and remarks. Other points than those previously cited in this abstract are that: all heat from the copper must flow transversely through the insulation; the thermal drop through the insulation in large, long-core, high-voltage, 60-cycle machines is of the order of 50 deg. cent.; the thermal drop in the insulation, in long-core machines can not be appreciably lowered by improvement in ventilation; thermometers placed on the end

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

windings, in general, give no information in regard to the highest copper temperature; resistance measurements taken after completion of the heat run, convey no information in regard to maximum temperature, and but little information in regard to the average temperature in the slots; the machine usually cools too much after shut-down and before taking readings to obtain accurate data on the average temperature of the winding.

The method of measuring temperatures by detectors in the upper coil is not usually commercial; therefore it would be best to continue with detectors between coils, protecting the detectors from external air currents. The detector reading is then a means of judging the maximum copper temperature, and as such may be used for comparison of readings between machines.

Calculation of Magnetic Force on Disconnecting Switches

BY H. B. DWIGHT

Electrical Engineer, Canadian Westinghouse Co.

THE practical problem of calculating the magnetic force tending to open a disconnecting switch is a useful one to solve. The result is expressed in concise form in formulas (**20**) and (**21**) and curves are also given in Figs. 3 and 4 from which the force may be found without using the formulas.

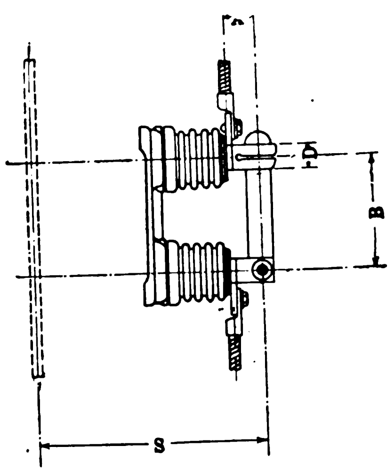

FIG. 1—FRONT-CONNECTED DISCONNECTING SWITCH

The solution of this problem is useful not only to the designers of switches who must design the parts so as to withstand the maximum force to be expected, but also to the designers of circuits containing disconnecting switches, for it is often desirable to choose a form of circuit which will produce the least possible force on the switch. The formulas and methods of calculation may also be used for calculating the forces on different parts of circuit breakers and other types of apparatus.

The mechanical force tending to move the blade of a switch which is carrying current, is proportional to the strength of the magnetic field in which the blade lies. The fundamental formula which should be used in making calculations of this kind states that the strength of the magnetic field at a point P, due to a small length of conductor $d\,x$ at a point Q is equal to

$$\frac{I\,dx\cos\theta}{P\,Q^2}$$

where I is the current in absamperes and θ is the angle between $P\,Q$ and the perpendicular from P to the line through $d\,x$. This may be found in standard text books such as J. J. Thomson's "Mathematical theory of Electricity and Magnetism," Fourth Edition page 356.

The field in which the blade lies is calculated in four parts, each depending on part of the typical circuit shown in Fig. 5.

TYPICAL CIRCUIT

This typical circuit consists of a flat blade of length B, two round arms of length A, and connections parallel to the blade. The diameter and shape of the parallel connections do not appreciably affect the result. A typical circuit of this type most nearly corresponds to disconnecting switches as used in practise, and it is believed that it gives a calculated force which is correct within a small percentage.

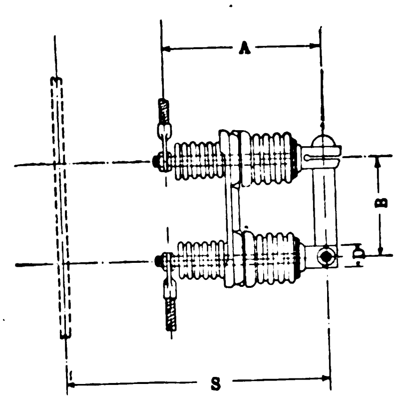

FIG. 2—REAR-CONNECTED DISCONNECTING SWITCH

The formulas are first obtained in algebraic form, but they are greatly simplified for practical use by engineers by expressing them as convergent series. Separate series must, however, be given for the two cases of A greater than B, and A less than B. For this purpose, the following series are required:

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

$$\text{logh}\,(x + \sqrt{1 + x^2}) = X - \frac{1}{2.3}x^3 + \frac{1.3}{2.4.5}x^5 - \frac{1.3.5.}{2.4.6.7}X^7 + \ldots \quad (8)$$

where X^2 is less than 1, and

$$\text{logh}\,(x + \sqrt{1 + x^2}) = \text{logh}\,(2\,x) + \frac{1}{2.2}u^2 - \frac{1.3}{2.4.4}u^4 + \frac{1.3.5}{2.4.6.6}u^6 - \ldots \quad (9)$$

where x^2 is greater than 1 and where $u = 1/x$

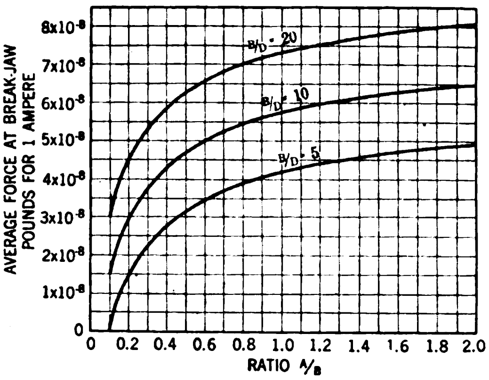

FIG. 3—REPULSION IN DISCONNECTING SWITCHES

The force varies as the square of the current.
Force due to return circuit not included.
B = Length of blade.
D = Width of break-jaw.

The force in pounds is obtained by multiplying the strength of field by the strength of the current—and by a constant depending on the units used.

The formulas for the four parts are as follows: First, the force due to flux cutting the blade, outside of the

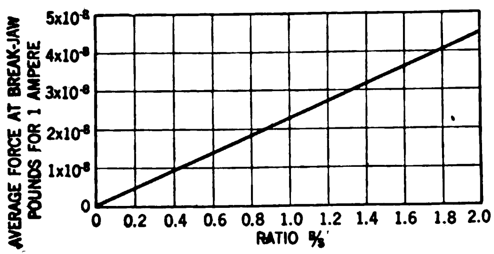

FIG. 4—REPULSION DUE TO RETURN CIRCUIT

The force varies as the square of the current.
B = Length of blade.
S = Distance from blade to return conductor.

break-jaw, caused by the conductor of length A, when A is greater than B, is

$$\frac{I^2}{4.45 \times 10^7}\left[2.30\log_{10}\left(\frac{B}{r}\right) - \frac{1}{4}\frac{B^2}{A^2} + \frac{1}{4}\frac{r^2}{A^2} + \frac{3}{32}\frac{B^4}{A^4} - \frac{1}{4}\frac{B^2C^2}{A^4} + \ldots\right]\text{pounds} \quad (10)$$

When A is less than B, the above force is

$$\frac{I^2}{4.45 \times 10^7}\left[2.30\log_{10}\left(\frac{2A}{r}\right) - \frac{A}{B} - \frac{1}{6}\frac{C^2}{A^2} + \frac{1}{4}\frac{r^2}{A^2} + \frac{1}{6}\frac{A^3}{B^3} + \frac{.1}{6}\frac{A\,C^2}{B^3} - \frac{3}{40}\frac{A^5}{B^5} - \frac{1}{4}\frac{A^3C^2}{B^5} + \ldots\right]\text{pounds} \quad (11)$$

Some of these terms are small and may be omitted.

Second, the force due to flux cutting the blade inside the break-jaw, caused by the conductor of length A, is

$$\frac{I^2}{4.45 \times 10^7}\left[\frac{1}{3} - \frac{1}{10}\frac{r^2}{A^2} + \ldots\right]\text{pounds} \quad (13)$$

This is, in an ordinary case, only about 8 per cent of the total.

Third, the force due to the connections parallel to the blade, shown by full lines in Fig. 5, when A is greater than B, is

$$\frac{I^2}{4.45 \times 10^7}\left[-\frac{B}{A} + \frac{1}{2}\frac{B^2}{A^2} - \frac{1}{8}\frac{B^4}{A^4} + \ldots\right]\text{pounds} \quad (16)$$

When A is less than B, this force is

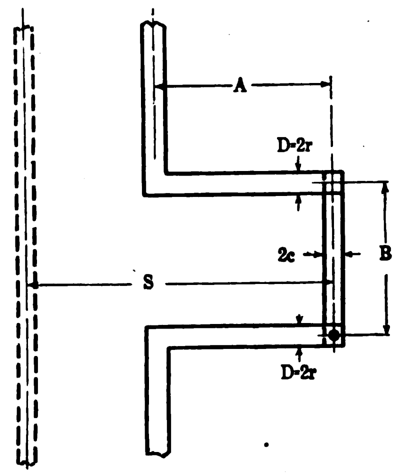

FIG. 5—TYPICAL CIRCUIT

$$\frac{I^2}{4.45 \times 10^7}\left[-1 + \frac{1}{2}\frac{A}{B} - \frac{1}{8}\frac{A^3}{B^3} - \frac{1}{8}\frac{AC^2}{B^3} + \ldots\right]\text{pounds} \quad (17)$$

Fourth, if the circuit returns directly behind the switch at a distance S, the force is

$$\frac{I^2}{4.45 \times 10^7}\left[\frac{B}{S}\right]\text{pounds} \quad (19)$$

Adding the above, the total force at the break-jaw is when A is greater than B,

$$\frac{I^2}{4.45 \times 10^7}\left[2.30\log_{10}\left(\frac{B}{r}\right) + \frac{1}{3} - \frac{B}{A} + \frac{1}{4}\frac{B^2}{A^2} + \frac{3}{20}\frac{r^2}{A^2} - \frac{1}{32}\frac{B^4}{A^4} + \frac{B}{S}\right]\text{pounds} \quad (20)$$

When A is less than B, the force is

$$\frac{I^2}{4.45 \times 10^7}\left[2.30\log_{10}\left(\frac{2A}{r}\right) - \frac{2}{3} - \frac{1}{2}\frac{A}{B} - \frac{1}{6}\frac{C^2}{A^2} + \frac{3}{20}\frac{r^2}{A^2} + \frac{1}{24}\frac{A^3}{B^3}\right.$$

$$+ \frac{1}{24} \frac{A\ C^2}{B^3} + \frac{B}{S} \Big] \text{ pounds} \qquad \textbf{(21)}$$

If I is the effective current in amperes, the force given by the formulas or curves is the average force. If I is the peak value of current as read from an oscillograph, the force is the maximum momentary force. If the circuit does not return behind the switch, the term $\frac{B}{S}$ is zero.

It would be desirable if the calculated solution of this problem were to be checked by laboratory measurements. No published measurements of the force on a disconnecting switch are known to the writer, but it should be possible to make such a measurement within an accuracy of a few per cent.

Example: $I = 30{,}000$ amperes, effective. $A = 15$ inches, $B = 20$ inches, $2\,C = 1.5$ inches, $D = 2\,r = 1$ inch. No return circuit behind the switch.

Result, the average force at the break-jaw is,

$$\frac{9 \times 10^8}{4.45 \times 10^7} [4.094 - 0.667 - 0.375 + 0.018]$$

$$= \frac{90}{4.45} \times 3.07 = 62 \text{ pounds.}$$

Using Fig. 3, $\frac{A}{B} = 0.75$ and $\frac{B}{D} = 20$

Therefore the average force is

$$9 \times 10^8 \times 6.9 \times 10^{-8} = 62 \text{ pounds.}$$

The maximum momentary force due to the above alternating current is 124 pounds.

Voltage Stresses in Reactors in Service

BY F. H. KIERSTEAD and ROYAL MEEKER

Both of General Electric Co.

THE authors have presented experimental data together with a physical explanation of the phenomena revealed. They have endeavored as far as possible to abstain from mathematics and obstruse theoretical considerations.

Comparison is made of the similarity between current limiting devices and limiting devices as regards the necessity for reliability and the authors point out the ease with which the latter may be tested and call attention to the difficulty of subjecting the former to service conditions by means of tests. The reason for the difficulty in demonstrating the ability of reactors to function properly in service is twofold. First, it is almost never possible to obtain a generator large enough to deliver the full short-circuit current through the reactor at the rated frequency and maintain across the reactor the circuit voltage for which the reactor was designed. Second, the voltage stresses that are obtained in a reactor with a generating system short-circuited through it are far more severe than would be obtained with a large generator alone discharging through the reactor. Because of this difficulty of observing the stresses in reactors while undergoing short-circuit conditions experimental data are presented indicating the magnitude of these stresses and their causes.

A large number of tests have been made with a 10,000-kilowatt generator short-circuited through reactors and it was impossible to observe the presence of high voltage stresses in the reactors.

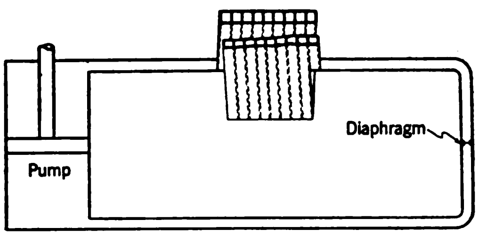

Fig. 7—No Stress on System

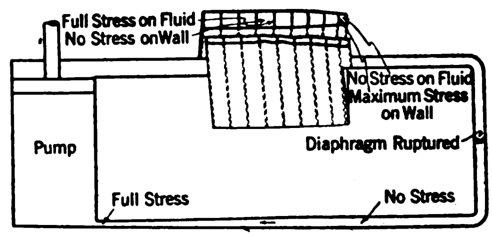

Fig. 10—System After Diaphragm Has Ruptured and Wave Has Entered Coil

If excessive voltages existed across the reactors they existed for too brief a period for the oscillogram to record them. There was no means of determining if the voltage stresses were distributed non-uniformly. The reactors showed no visible signs of distress.

In such short-circuit tests high voltage stresses may occur at the time the short circuit is made and at the time of interrupting the short-circuit current. Between these two periods there exists only the reactive voltage due to the short circuit current.

Investigation was made of the voltage stresses at the instant of making short circuits and also at the instant of the interruption of short-circuit current, and the

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

results of these investigations have been included in the paper.

Attention is called to the fact that the reactors in service may have greater voltage stresses in them than could be caused by the short-circuit tests above referred to for two reasons:

1. They may be subjected to lightning impulses.
2. They may be subjected to high voltages due to resonance.

The results of both of these causes of high stresses are recorded in the paper.

A. Voltage Stresses at Instant of Short Circuit

At the instant a short circuit occurs on an electric circuit the voltage at that point drops to zero, while the voltage at all other points except those immediately adjacent to the short circuit, are still at full value, and the short circuit results in a traveling wave of steep front.

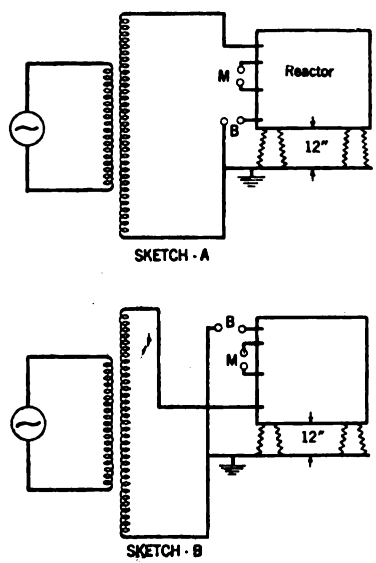

Fig. 11

In the paper it is shown how such a steep wave is caused in a hydraulic circuit and the close analogy between the hydraulic circuit and electric circuit brought out.

With experimental data it is shown that in an electric circuit a wave of not greatly over 30 ft. in length may be produced by a sudden short circuit.

A close analogy exists between the hydraulic system shown in Fig. 7 and the electric system shown in Fig. 11, and Fig. 10 shows the effect of a steep wave front on the long cylindrical ring with hollow cross sections to be similar to the effect of a steep wave front upon a reactor. The experimental data given in the paper prove that this conception is correct since the stresses which were measured between layers accords with the conception of the stresses on the diaphragm shown in Fig. 10.

Investigation has been made of the stresses between turns and layers of a reactor with and without a resistor shunting the reactor and the results show a marked reduction in stresses due to the presence of the resistor.

Summarizing, the paper shows the following:

1. That steep waves may be produced by the sudden drop in voltage caused by a short circuit.
2. That the initial distribution of a steep wave across an inductance is determined by the amount of energy stored in its capacity to ground which must be discharged in order for the waves to progress through the inductance and by the capacity between turns and layers of the inductance through which the energy must be discharged.
3. That a resistance shunting an inductance reduces the voltage stresses caused by steep waves.

B. Voltage Stresses at The Instant of The Interruption of a Short Circuit Current

The voltages that may occur across reactors at the time of interruption of a short circuit current may depend upon the switch which interrupts the current, the value of the current interrupted, the voltage of the circuit interrupted and the amount of inductance and electrostatic capacity in a circuit interrupted. In the majority of cases the switch itself acts as a safety valve limiting the voltage by drawing an arc between the blades of the switch and thereby prolonging the current until a favorable time occurs for the current to die out. To determine how the above conditions affect the voltage stresses in reactors investigations were made as follows:

1. To determine the variation in voltage rise across a reactor with the amount of current interrupted.
2. To determine the effect of different speeds of interruption of current on the voltage rise.
3. To determine the variation of the voltage rise with the point on the current wave or which the switch starts to open.

The results of these investigations are given in the paper. The conclusions, drawn from these investigations, are as follows:

1. The voltage obtained across a reactor due to the interruption of a direct current is independent of the applied voltage and depends on the current to be interrupted and the rate at which it is interrupted.
2. The voltage across a reactor due to the interruption of alternating current with commercial switches is in general independent of the current interrupted and depends on the impressed voltage, and will be approximately equal to double the impressed voltage. If, however, the circuit is opened by a switch so quick acting that the current is interrupted before it can reach its zero value in accordance with its normal curve, then the voltage will depend upon the current interrupted and the rate at which it is interrupted.

C. Voltage Stresses in Reactors Due to Impulse Waves

The paper shows the anology between the circuits which were used to produce impulses similar to lightning impulses and a hydraulic circuit. It is shown, that the effect of impulse voltages in stressing up the

reactors is similar to the case described in section A with two exceptions:

1. Both ends of the reactor feel impact of the wave.
2. The wave front is not so steep due to the longer conductors involved in this latter case.

The investigation of the effect of the impulse waves on the reactor is divided as follows:

1. The effect of shunt resistance on the voltage across a reactor.
2. The effect of shunt resistance on the distribution of the voltage stresses in reactors.
3. The effect of extra end-turn and end-layer spacing on the stresses in reactors.

The conclusions drawn from the tests of the effect of impulse voltages on reactors are as follows:

1. Impulse waves may cause non-uniform distribution of the stresses in a reactor. The distribution of these stresses between turns and layers of the reactor depends upon the distribution of the capacity between turns and layers of the reactors and upon the wave shape.
2. Resistance connected to the reactor winding effects a reduction of these voltages stresses. The amount of the reduction depending upon the magnitude of the resistance.
3. Extra spacing of the end-layers and end turns of the reactor winding causes greater concentration of voltage stresses on the extra space parts. Apparently no increased insulation strength against impulse voltages is gained by extra spacing the end turns and layers.

Attention is called to the additional advantage gained by using a resistance having the characteristics of presenting a higher resistance to low voltages than it does to high voltages.

D. Voltage Stresses in Reactors Due to Resonance

An analogy is drawn between mechanical resonance and electrical resonance. There is also shown the similarity between a generator delivering energy at the proper frequency to an inductance in series with a capacity and a large condenser delivering energy by means of oscillatory discharge at the proper frequency to an inductance in series with a small capacity. The authors measured resonant voltage across a reactor nine times as great as the applied voltage. It is explained how these resonating circuits can be obtained in ordinary generating systems. It is also shown that these voltages appear on the other apparatus and cables in the circuit.

The simplest means of preventing resonant voltages occurring is to shunt the reactors in the system with resistors. By so doing, any tendency for rise in voltage across the reactor due to resonance causes an energy loss in the resistor proportional to the square of the voltage rise and therefore the loss soon reaches a point at which it is equal to the energy delivered which fixes a maximum point to which the voltage may rise. Experimental data presented in the paper shows this to be true.

In this paper is shown a method of calculating the limits to which the resonant voltage may rise if there be no resistance in the circuit, and experimental data show the method given to be in accordance with results obtained in practise. The outstanding features of the investigation covered in this section of the paper are three-fold.

1. Resonant voltages are obtained in circuits similar to those used in electric generating and distributing systems.
2. Resonant voltages in circuits having high capacity are enormous.
3. Resonant voltages are entirely eliminated by a resistor.

The paper concludes by calling attention to a series of events that are linked together which will cause destructive voltages in reactors.

Stability of High-Power Generating Stations

BY CHARLES P. STEINMETZ

Consulting Engineer, General Electric Co.

I. Power Limitation

WITH the increasing use of electric power, the size of electric generating systems has steadily increased, from the small high-frequency stations of the early days, to the huge metropolitan systems of today. This created the problem of limiting the destructiveness of the power which can accidently be concentrated at any point of the system.

With increasing size, systems were divided into several generating stations, more economically to cover the territory, and under present conditions there appears no material gain in going much over a hundred thousand kilowatts in a single station.

Economy and reliability of operation demands paralleling of the entire system, and synchronous operation of all the generating stations thus is the universal custom.

At the high distribution voltages necessary in these systems, the impedance of lines and feeders does not materially limit the destructive power concentration possible at any point in case of a short circuit. The steam turbine type of alternator, universally used, inherently gives relatively much greater momentary short-circuit current than the low-speed machines of former times.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

Thus power-limiting devices have become necessary and are universally used in all modern high-power systems. Such consist of:

(1) *Power-Limiting Generator Reactors*, inserted between the generator and the busbars, where the internal self-inductive reactance of the generator cannot be made sufficiently high without material sacrifice of its other characteristics.

The reactance permissible in the generator leads necessarily is limited to the amount which does not materially increase the total synchronous reactance.

(2) *Power-Limiting Busbar Reactors* thus become necessary. Such busbar reactors should be as high as possible, effectively to limit the power which can flow over them into a short circuit on one busbar section, but still low enough not to interfere with such flow of current along the busbars, as required under the variations of the load.

With all the stations or station sections tied together into a ring bus by power-limiting busbar reactors, the maximum power which may have to flow over the busbar reactors theoretically is one-quarter that of the smallest generator on the busbar section. Busbar reactors thus may be of much higher reactance than generator reactors.

Interchange of power over busbar reactors occurs without voltage drop, by a phase displacement between the voltages on the two sides of the reactor, and a 25 per cent reactance, referred to the rating of one generator, is ample for the interchange of current, with negligible phase displacement.

(3) *Feeder Reactors*. Even with generator power-limiting reactors, and busbar dividing reactors, the effect of a short circuit at or near a busbar section is very severe, and probably shuts down this section. As troubles in feeder cables are very much more frequent than at the busbars, the installation of feeder reactors greatly reduces the frequency of serious troubles. While a feeder reactor may be a relatively small percentage, referred to the feeder capacity, it is large relative to the station capacity. It therefore greatly reduces the shock of a short circuit on the system, maintains some voltage on the busbars, and thus, if properly chosen, protects against the dropping out of synchronous apparatus. Also, by permitting a more rapid opening of the circuit breakers, it reduces the duration of the trouble.

The installation of power-limiting reactors made the safe operation of our huge power systems possible, and permits their increase to any size, millions of kw. generator capacity, with the same reliability and safety of operation.

The question then arises, what effect this necessary sectionalizing of the system by reactors has on the synchronizing power of the system, and thus on the stability of operation, the more so as in case of trouble a local and temporary drop of voltage may still further lower the synchronizing power.

The seriousness of this problem was again illustrated by some troubles which occurred in 1919 in the 25-cycle generating system of the Commonwealth Edison Company of Chicago: Four stations are connected together by power-limiting busbar reactors, with about a quarter million kw. of connected generator capacity, at 9000 volts. A short circuit occurring in a middle station opened and the system cleared in three to four seconds. But the voltage, which should have come back immediately after opening the short circuit, did not come back and could not be brought back, with the generators fully excited, but remained at zero in the affected station and the next adjoining one, for a quarter of an hour, while the other two stations gave low voltage. Then the voltage suddenly came back to normal. As the result of the short circuit, the two generating stations, and the individual generators in the two stations, had broken out of synchronism and were drifting past each other, unable to pull each other into step, until after a quarter of an hour.

On May 19, a short circuit occurred at the generator of one end station, immediately opened and the system cleared, but the voltage remained low and wildly fluctuating in all four stations, giving a voltage chart looking like hunting of the generating stations against each other, though it is doubtful whether it was real hunting. After a quarter of an hour, the voltage suddenly came back to normal and the stations steadied down.

The question of the synchronizing power of these big stations, as affected by the impedance between the machines, thus is of fundamental importance for their safe operation, and is further investigated in the following.

II. Parallel Operation of Synchronous Machines

A. Steady Strain. This gives the equations of the flow of power, current, phase displacement of two alternators, stations or station sections connected together through an impedance and loaded so that a steady flow of power occurs over the connecting impedance, and gives the conditions of maximum synchronizing power, etc.

B. Oscillation. This gives the equations of a system of two alternators, or group of alternators interconnected by an impedance and oscillating against each other, and discusses the synchronizing power transfer, the current flow, limits of synchronizing power, etc.

C. Slipping. This gives the equations of a system of two alternators or groups of alternators interconnected by an impedance and out of synchronism with each other, that is, slowly drifting past each other. The equations are given of the periodic power transfer, the fluctuation of current, the pulsation of speed, and the maximum frequency differences, from which the machines can pull each other into step, as related to the mechanical momentum of the machines, etc.

D. Pulling in Step. This gives the equations for the same case as *C*, when the frequency difference is too large for the machines to pull in step quickly, and derives the equations of the steady continuous power transfer, which gradually brings the machines closer together in frequency, until they are so close, that they can pull in suddenly, in a half cycle, and thereby change from slipping to synchronous oscillation which gradually steadies down to steady parallel operation.

III. Discussion

The meaning of the terms entering the preceding equations, and their numerical values, are discussed and applied, and a number of conclusions derived, such as that the synchronizing power is a maximum, when the true self-inductive reactance of the machine or group of machines is half the effective or equivalent reactance of armature reaction. The minimum voltage, at which turbo alternators still have sufficient synchronizing power to stay in step with each other when suddenly full load is thrown off, is of the magnitude of half of normal voltage.

The curves of voltage drop of turbo alternator stations as the result of a short circuit beyond a feeder reactor, and the curves of voltage recovery after the opening of the short circuit are calculated and their relation to the remaining in synchronism or dropping out of step of generators, synchronous converters, etc. is discussed.

Considerations Which Determine the Selection and General Design of an Exciter System

BY J. T. BARRON

General Superintendent of Production, Public Service Electric Co., Newark N. J.

AND

ALEX E. BAUHAN

Superintendent of Stations Pennsylvania Water and Power Co., Baltimore, Md.

It is the purpose of this paper (a) to discuss the factors which determine the selection of an exciter system for a generating station and (b) to discuss other general design features of excitation systems. No attempt is made to recommend any particular system for general application but rather to present a method analyzing the problem for a particular case.

Excitation systems may be roughly classified as:

A—Central system with separately driven exciters.

B—Central system with direct-connected exciters.

C—Individual system with direct-connected exciters.

D—Individual system with separately driven exciters.

Part I—Consideration of Factors which Determine the System to be Used

The accompanying tabulation compares in a general way the various systems from the standpoints indicated in the first column.

Part II—Consideration of Matters Related to the Layout of an Excitation System but not Mainly Concerned in the Choice of System

1. *Number and Size of Exciters.* Where system A is used for small and moderate size stations the minimum requirement is two exciters each, large enough to supply the entire excitation requirement, and the usual maximum requirement is three exciters, any two of which can carry the load. For the very large station the minimum is three exciters and the usual maximum four exciters, any two of which can carry the entire load in either case.

In systems *B* and *C* each exciter is usually made large enough to supply its own unit. Spare equipment is provided by a motor-driven set or by making direct-connected exciters oversize.

In system *D* each exciter should be large enough for its own unit with a motor-driven spare machine. Two a-c. exciters are usually provided, each of which is large enough to carry entire load. Transformer connection to main bus should also be provided.

2. *Kind of Drive.* Referring to system *A*, if two exciters are provided, both should be prime mover driven. If there are three or four exciters, at least two should be prime mover driven. Combination prime mover and motor drive may be used in hydro plants subject to ice or trash trouble and for manipulation of heat balance in steam plants. Generally speaking, induction motor drive is preferable to synchronous motor drive.

3. *Shunt vs. Compound Exciters.* The compound-wound exciter is not recommended for parallel operation especially when used with voltage regulators.

4. *Voltage.* 125 volts is satisfactory for small plants but for moderate size and large plants 250 volts is preferable from the standpoint of reduced cost and size of apparatus and cables. It is suggested that consideration may be given to the use of 500 or 550 volts in large plants.

5. *Bus Arrangements.* For system *A* and the a-c.

COMPARISON OF SYSTEMS

	A Central Separate	B Central Direct	C Individual Direct	D Individual Separate
(1)—Power Supply to Auxiliaries	Good	Good	Not Suitable	Excellent
(2—Automatic Voltage Regulation	If used for auxiliaries or with battery requires booster system of regulation		Permits use of individual regulators	
(3)—Use of Storage Battery	Most advantageous use of battery. Requires booster system of regulation		Battery cannot be floated. Can be used only with complications	
(4)—Space Requirements	Large	Small	Small	Large
(5)—Initial Cost (A = 100%) Low head hydro	100%	70% to 90%	70% to 90%	120% to 140%
Steam or high head hydro	100%	50% to 70%	50% to 70%	120% to 140%
(6)—Efficiency (hydro, excluding rheostats)	Good	Excellent	Excellent	Poor
(7)—Effect of Power System Troubles (a) Sustained Short Circuit	Prime mover driven exciters unaffected. Speed of motor-driven exciters affected	If speed increases, higher short-circuit currents and better synchronizing power. If speed decreases, lower short-circuit currents and lower synchronizing power		Unaffected
(b) Sudden loss of load	Speed of motor driven exciters affected	Speed of exciters affected		Unaffected
(c) Generators falling out of step	Speed of motor driven exciters may be affected	Speed of some of exciters affected. Synchronizing power may be decreased		Unaffected
(d) Opening of fields to clear line trouble	Excitation unchanged	If speed is below normal generators are more likely to fall out of step due to poor reduced excitation		Excitation unchanged
(e) Splitting station with regulator potential on one section and compensating coil on other section	Voltage fluctuation equal to twice line drop compensation results		Unaffected with individual regulators. If only one regulator voltage fluctuation results	
(f) Shut-down of generator with direct-connected exciter needed for other units	Unaffected	Serious disturbance to service	Loss of excitation on a running generator which may fall out of step	Unaffected
(8)—Effect of Exciter System troubles (a) Ice and trash (hydro)	Serious reduction of service unless ample motor driven spare is available	Unaffected	Unaffected	Serious reduction of service unless ample motor driven or transformer spare is available
(b) Short-circuited exciter	Unaffected if exciter can be spared. Serious if exciter cannot be spared		If generator is large in comparison with size of system it may fall out of step	
(c) Short circuit on exciter bus	Short circuit usually clears itself. If not total interruption results		Unaffected	Short circuit usually clears itself. If not total interruption results
(d) Accidental shut-down of exciter	Serious disturbance unless exciter can be spared		Unaffected	If d-c. exciter, may cause generator to fall out of step. If a-c. exciter serious disturbance unless machine can be spared
(e) Open circuit in exciter field	Serious disturbance unless exciter can be spared		Generator may fall out of step	
(f) High voltage from opening last exciter breaker	Affects entire excitation system. May cause breakdown of insulation. Will blow fuses and breakers on auxiliary circuits		Ordinarily not possible. In any event affects only one unit	
(g) Regulator troubles	Affects entire system		Affects entire system if only one regulator is used and only one unit if individual regulators are used	
(9)—Simplicity physical	Simple for small or moderate size station. Complicated if many exciters and battery are used		Very simple for small number of generators. Complicated for large number of generators	Complicated
Normal Operation	Simplest	Simple	Simple	Complicated
During Trouble	Simple	Complicated	Complicated	Simplest
(10)—Reliability	Depends on number of pieces of equipment, amount of remote control, automatic and regulating devices.			

side of system *D*, a single bus is sufficient in most cases. A double bus gives all the flexibility that might be desired.

In systems *B* and *C* and the d-c. side of system *D*, a single bus for the use of the spare capacity and facilities for throwing any exciter either on this bus or on the field of its own generator is sufficient.

6. *Protection.* The minimum amount of automatic protective equipment consistent with safety to service and apparatus should be installed. Exciter battery and generator field breakers should have no overload protection. Exciter breakers should have reverse current trip if operated in parallel or with battery. Rotating equipment which is likely to run away should have overspeed trip. Use of electrolytic arresters to prevent high voltages is advisable. Ground detectors in the form of lamps should be used. Any overload relays used on motors should function only in case of short circuit and not when motor is pulling back after a voltage disturbance.

Factors in Excitation Systems of Large Central Station Steam Plants

BY J. W. PARKER and A. A. MEYER

Both of Detroit Edison Co., Detroit, Mich.

REALIZING that the excitation system is an important factor in successful operation of a large turbo-generator plant, careful attention should be given to the design of a most practical scheme. Underlying principles like simplicity, measured reliability, limited flexibility should not be lost sight of. Probabilities, rather than all possibilities should be carefully weighed and provisions made to meet only the former, rather than introduce a complication of safeguards just as apt to cause trouble.

There are two commonly found methods of providing excitation; one from a common bus, the other by means of individual exciters. A variety of schemes can be devised which are based on one or the other. The common bus method is perhaps the older of the two, but seems to be giving way to the individual exciter schemes employed in more recent practise. The important consideration is that the employment of a common exciter bus entails the maintenance of an additional energy system, secondary to the main energy system, but equally important, and requiring safeguards and careful attention to insure continuity and good regulation.

The individual exciter scheme is growing in popularity because simplification is easily attained. Disturbances in the excitation system are limited to a single generator, instead of endangering the entire plant. The scheme also lends itself well to expansion with increase in station capacity. Additional excitation equipment can be installed in like ratio with the main generator units, and without disturbing or even affecting existing equipment.

The best means of driving exciters depends upon the general method of excitation. With the common bus scheme it becomes more difficult. Prime movers are sometimes employed for driving exciters, but have not been altogether satisfactory in such small sizes as are usually required.

Motor drive has been more successful. Reliability in the latter case has been secured to a high degree by throwover to two sources of energy, one the auxiliary power bus, the other the main station bus. With the individual exciter scheme, a simple solution has been obtained by direct connection of the exciter to the main generator shaft. The exciter benefits by the good speed regulation of the most accurately governed prime mover in the plant, the main unit. The question of reliability of the prime mover driving the exciter as well as the attention of the turbine room operator to an additional machine is automatically eliminated. There is one objection raised to the direct-connected exciter, because the possible loss of the exciter entails losing from commission the corresponding main unit. This chance, however, may be so minimized as to leave very little hazard.

Standby excitation to the main generator seems more necessary with the common bus method than with the individual exciter scheme. This is evident from the fact that the exposure of the common bus is greater and trouble at any one point affects the whole plant. Standby in most cases consists of a battery floating on a common bus, usually the normal excitation bus. A battery so connected also acts very efficaciously as a stabilizer of the load fluctuations and vagaries of the several exciters paralleled upon the bus. In case of direct-connected exciters, standby provision is not so necessary and is frequently omitted without any great hazard. Where standby is provided for individual exciters, throwover from normal to the reserve source of excitation is sometimes accomplished automatically.

Control of excitation is much more simple with the individual exciters than if common bus excitation were employed. In the former case, only a small exciter field rheostat is necessary, whereas in the latter case a large field rheostat is required in addition to the exciter field rheostat. In either case all rheostats are regulated very satisfactorily by the station operators, according to the desirable division of energy as well as the reactive components among the various machines. This is necessary to obtain the best overall plant economy of the main units. Only in a few cases, perhaps, where the load fluctuates rapidly, is automatic regulation really desirable.

It is pointed out that for best economy every prime mover in the plant should be the most efficient machine available of its relative type, and therefore that exciter generators should drive their energy directly or indirectly from either the main turbine or an auxiliary turbine carrying the combined load of a member of plant auxiliaries. A direct-connected exciter may accordingly afford the maximum of economy as well as the major feature of reliability.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29—July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

Exciters and Systems of Excitation

BY H. R. SUMMERHAYES

Lighting Dept., General Electric Co. Schenectady, N. Y.

IN laying out excitation systems for central power stations continuity of service is the primary requirement. First cost and economy in operation are secondary requirments which must be given due weight.

Exciter design, method of drive, wiring and connections, method of control and reserve capacity are considerations affecting reliability.

Systems of excitation are considered under:

1. *Common Excitation Plant* (exciters operating in parallel on a bus supplying the fields of all generators.)
2. *Individual Exciters* (not operating in parallel.)

Common excitation plant has predominated in American practise for many years, while European practise has shown more preference for individual exciters. In recent years American practise has tended more and more toward individual exciters.

Of the steam turbines 7500 kv-a. and over, sold by one manufacturer during the past five years, about 45 per cent were equipped with direct-connected exciters; and of the hydroelectric generators 1000 kv-a. and over, about 75 per cent had direct-connected exciters, and an additional percentage had individual motor-driven exciters.

Common excitation plants have the chief advantage of constant bus voltage, permitting floating storage battery on exciter bus, a plan much used in important lighting stations to insure against shut-down due to excitation trouble.

With individual exciters the circuits are short and simple, and trouble with one exciter affects only one generator.

Methods of Drive are discussed for both individual and common excitation plants with the conclusion that for large plants direct-connected exciters are most reliable, efficient and less costly whenever speed requirements allow their use.

Volts Pressure of Exciter Plant is standard at 125 volts, except for large plants, when considerations of alternator and exciter design, expense of bus bars, connections, switches, etc, dictate a choice of 250 volts.

Excitation Requirements as to kilowatts and voltage range are discussed. Kilowatts required vary from 1.5 per cent down to 0.53 per cent of alternator rating. Individual exciters must operate down to 30 or 40 per cent of rated pressure. Continuous rated exciters should be chosen 20 per cent larger than stated excitation kilowatts.

Exciter Rheostats for use with voltage regulators should have resistance three to four times that of exciter field. For individual exciters rheostats should have 100 to 150 steps so as to get close graduation at the lower pressures.

Electrically operated rheostats are preferred for convenience of operation and location near alternators.

Exciter Circuit Breakers and Field Switches should be non-automatic on overload. Exciter breakers should operate automatically on reverse current and field switches automatically only in connection with balanced or reverse-current protective systems which operate the oil circuit breaker in the alternator circuit.

Electrical control is advocated for large plants, to permit location near machines and operation from main switchboard.

Exciter Batteries are installed in important stations either floating or in reserve.

Methods of charging are discussed. The control bus for electrically operated circuit breakers should be separate from the exciter bus, which is subjected to high transient voltage from the alternators in case of short circuits on the a-c. system.

Shunt Exciters are recommended for individual exciters, or for exciters operating in parallel with batteries on account of less chance of motoring and polarity reversal.

Compound Exciters are recommended for parallel operation without battery and on account of better maintenance of voltage and less rheostat adjustment required.

For operation with regulators there is little choice between shunt and compound, shunt being better when wide range or sensitive regulation is desired.

Commutating Pole Exciters for parallel operation, whether shunt or compound must have a drooping characteristic when operating without series field. For parallel operation over wide voltage range the design should be such that a slight forward brush shift may be used, in connection with a somewhat weak commutating field. With such a machine a drooping characteristic is obtained over a wide range of voltage and satisfactory parallel operation ensured, whether shunt or compound.

Voltage Regulators are not generally used in the largest city central stations on account of the proportionally small load fluctuations, excepting where such loads as steel mills or railroad electrification are supplied.

They are commonly used on hydroelectric plants where the fluctuations of load are larger and governing not so good. They can be made to take care of exciters operating individually or in parallel, with one

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

or multiple regulators, up to the largest plants in use or contemplated.

Station Auxiliaries in their relation to the choice of exciter plant are discussed. The conclusion is reached that for large plants direct-connected individual exciters should be used, with emergency bus, and battery. The emergency bus should be supplied by one or more motor generators driven from the a-c. auxiliary bus supplying the other station auxiliaries. Thus the excitation is normally kept separate from the house plant or station auxiliary bus. The latter, supplied by a relatively large and efficient turbine forms a reliable supply for the station auxiliaries, with possibility of efficient heat balance in a steam plant and a reliable emergency supply for the excitation, unaffected by main bus disturbances.

Application of D-C. Generators to Exciter Service

BY C. A. BODDIE and F. L. MOON

Both of Engineering Dept., Westinghouse Electric & Mfg. Co.

THE purpose of the paper is to discuss some of the problems which arise in connection with the use of d-c. machines as exciters; such as choice, range and stability of exciter voltage ,stability of parallel operation, responsiveness, use of main rheostats, and use of compound field windings.

The choice of exciter voltage is usually not a matter of great importance; yet in some cases there are good engineering reasons for choosing 125 volts rather than 250, or the reverse. When automatic regulators of the Tirrill type are used, the exciter must be capable of operating over a range from two to one to three to one; the maximum voltage required being 10 or 15 per cent above the rated value. If the exciter has considerable cumulative series field, it may be difficult to obtain the required minimum voltage.

Where automatic voltage regulators of the Tirrill type are employed, a responsive system is necessary to avoid hunting of the regulator; otherwise the regulator main control must be damped until the whole system is very sluggish. The responsiveness of the system depends chiefly upon the quickness with which the exciter voltage responds to changes in its field resistance and upon the speed with which the alternator field current responds to changes in the exciter voltage. The time rate of change of the voltage of a d-c. machine when its field resistance is altered, is proportional to the instantaneous difference between the $I\ R$ drop in the field circuit, and the terminal voltage of the machine, that is, the "opening" between the magnetization curve and the volt-ampere characteristic of the shunt field circuit, as measured in volts: and is inversely proportional to the interlinkages of flux and field turns at rated voltage. A number of secondary factors have an influence upon the final result.

The problem of running exciters in parallel is largely the same as with other d-c. machines. Where Tirrill type regulators are used, the situation is more complicated owing to the range of voltage over which the machines must operate. There are several ways in which the drooping characteristic necessary for stable parallel operation may be obtained; and in general it may be said that in any case exciters may be made to parallel satisfactorily. Further, when automatic voltage regulation is used approximately correct load division at all voltages is ensured by making the maximum voltages the same, and making the average rate of decay of voltage about the same as the average of building up for each exciter.

Differential series windings are not detrimental to regulator performance and in some cases may be of benefit in promoting stability of parallel operation. Cumulative series windings, if they constitute a considerable portion of the total field strength may seriously impair the quality of regulation obtained. In some cases trouble from polarity reversal of compound-wound machines under abnormal conditions, has been experienced. Sufficient cumulative series to balance the demagnetizing armature reaction in a non-commutating pole machine, is not only harmless but is desirable; and is very necessary where broad range regulating is used, in order to avoid polarity reversal.

When the exciters are connected to a common bus the excitation voltage cannot be varied to suit the needs of an individual generator; and a field rheostat or equivalent device is needed. When individual exciters are used, the excitation may be controlled by adjusting the exciter field rheostat, or by means of main field rheostat or equivalent. When it is considered safe to rely entirely upon automatic voltage control, the main rheostat may be omitted entirely or reduced to a small affair. Where thoroughly dependable hand control is desired, the question of exciter voltage stability must be considered. At the lower exciting voltages, rather poor control over the exciter voltage is experienced; hence it would be desirable to have some variable resistance in the main field circuit to render unnecessary the operation of the exciter upon the straight part of its magnetization curve.

One of the two fundamental ways of improving the response of an exciter is to increase the "opening" between the magnetization curve and the volt-ampere

---

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

characteristic of the shunt field circuit, though the possible gain is quite limited for several reasons. The other way is to reduce the number of interlinkages at rated voltage. As this depends partly upon the magnetic flux, some gain may be made by a reduction in the value of the flux. However the principal gain comes from a reduction in the number of turns; as this means a corresponding increase in the field current, the latter may require attention. The current which the shunting relay contacts can handle is limited in value, the limit lying between 20 and 25 amperes unless the block of resistance shunted by the contacts is abnormally small. If the needed reduction in the number of turns makes the field current too high, which is liable to happen if the exciter is built on a relatively large frame, the current must be split up among two or more circuits, as by winding the coils with several conductors in parallel, or by series parallel connection of the field coils.

The method of driving exciters by connecting them directly to the main units, has a definite relation to exciter design. On account of their disproportionate cost, direct-connected exciters are not often used with low-speed, small capacity units; and on account of the difficulty of building satisfactory d-c. machines for very high speeds, they are not often used with high-speed turbo-generators. For low-speed, large capacity units the exciters, if direct-connected, must be built on a relatively large frame, as a result of which they are inherently sluggish. However, they can be made very satisfactory from the voltage regulator standpoint by some of the methods mentioned above.

Exciter Practise in the Northwest

BY J. D. ROSS

Supt. of Lighting, Member Board of Public Works, Seattle, Wash.

EXCITER practise in existing Pacific Coast plants is indicated in a table giving the number and size of generators, the number and size of exciters with their drive, the manner of connection and whether a regulator is used or not, for the largest or newest hydroelectric plant of each large power company in British Columbia, Washington, Oregon and California.

Because of the difference in size and characteristics of machines whose fields are fed from the same exciter bus, and because of its complication and its tendency to pile up the voltage on a short circuit, the automatic regulator is little used in Northwestern plants.

For a new 15,000-kw. hydroelectric unit being added to the Cedar Falls station of the Seattle system, the writer chose an exciter large enough for a 36,000-kw. plant, the full final development of the entire station, so that only one exciter will be operating at a time. This design was preferred to that of an individual exciter for each generator, because of its greater simplicity especially since a regulator is to be used. The idea of simplicty is further emphasized in this plant by making the new generator and its transformer a unit, without intermediate busbars, using mica insulation, class B, throughout in both generator and transformer.

Auxiliaries are driven from an auxiliary bus energized by a prime mover and a battery, and entirely separate from the exciters, assuring a steady voltage for auxiliaries and removing a complication from the exciter system.

The same plan of excitation is followed in the new 15,000-kw. unit being added to the steam plant in Seattle, where 35,000-kw. three-unit plant will be controlled through one exciter, steam turbine and motor-driven. In order to get a large enough exciter of the proper speed, one exciter generator is mounted on each end of a shaft, with exciter turbine and motor between. In the new steam unit also the generator and transformers are connected together directly, without intermediate buses.

The writer sees no logical excuse for the compound-wound exciter; it tends to pile up the voltage on a short circuit, and to give much trouble in paralleling. The shunt wound machine with ample voltage range is ideal.

The trend on the Coast is away from small generators of different characteristics to large and uniform generating units. A number of plants are using combined waterwheel and induction-motor drive for at least one of the exciters. One company uses an exciter on each main unit shaft, each exciter large enough to supply two generators, with no added spare exciter. Another company uses the same plan but adds a spare exciter unit, driven by a motor.

The ideal exciter system for an entirely new plant is one in which each generator has its own shunt-wound exciter, driven by prime mover and having its own regulator. This allows a new generator to be ordered with its proper exciter regardless of changes in design of machines. In adding a machine to an old plant having its exciters connected to a bus, the use of one large exciter to operate the entire plant is the best compromise. The old exciters may then be used as duplicates.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

Generator Excitation Practise in the Hydroelectric Plants of the Southern California Edison Company

BY H. H. COX and H. MICHENER

Both of the Southern California Edison Co., Los Angeles, Cal.

THE writers describe the installation and operation of exciters at the generating stations and substation of the Southern California Edison Company. The system includes two 240-mile, 150,000-volt lines, which constitute probably the most extreme range of excitation of any system in operation.

The plants connected to these lines are Big Creek Power Houses Nos. 1 and 2, each with 32,000 kw. installed capacity, Eagle Rock Substation with 54,000 kv-a. installed step-down transformer capacity, Kern River No. 3 with 32,000 kw. installed capacity which will be put into operation in the latter part of 1920, and Big Creek Power House No. 8 with 22,500 kw. installed capacity which will be put into operation during 1921.

At the plants Nos. 1 and 2, each with two 17,500 kv-a. generators, there are two 150-kw. exciters respectively, one exciter of each set being also coupled to an induction motor. The exciter fields in station No. 1 are supplied from a motor-generator set, called an agitator, consisting of a 250-volt d-c. and a 125-volt d-c. machine connected in series opposition driven by an a-c. motor. The 250-volt machine is under control of a standard range Tirrill regulator controlling it from 125 to 250 volts. The resultant voltage, 0 to 125 volts, of the two machines is taken to excite the fields of the main exciters, giving them a range from 0 to maximum. At plant No. 2 the exciters are under control of a broad range regulator controlling their voltage from residual to maximum.

At Eagle Rock Substation, two 15,000-kv-a. synchronous condensers have direct-connected exciters, with one motor-driven exciter for a spare machine. The exciters are controlled by broad range regulators.

The system of operation of the existing plants starting from dead is described in detail.

In the new Kern River No. 3 power plant, with two 17,500-kv-a. generators, each generator is to be equipped with direct-connected exciters and one spare one, each of the three exciters being controlled by a separate broad range voltage regulator. In the plans for the Big Creek Power House No. 8, the initial development of which will consist of one 25,000 kv-a. unit, an exciter will be direct-connected to the generator shaft. A spare exciter will be kept at the power house, not connected to any motive power, to replace a burned out exciter on the generator in case of accident.

Abstract of paper to be presented at the A. I. E. E. Annual Convention, June 29–July 2, 1920. Advance copies of the complete paper can be obtained as soon as available by applying to Institute headquarters.

REORGANIZATION OF THE EXECUTIVE DEPARTMENTS OF THE GOVERNMENT

The Joint Committee on the reorganization of the executive departments of the Government was approved by the Senate when it adopted the Smoot-Reavis resolution. The prime reason for this resolution and the thing that made its passage possible in the Senate has been the activity of engineers in their campaign to secure a National Department of Public Works.

The bill provides for study of all the Federal administrative offices by three members of the Senate and by three members of the House, who are to report their findings not later than the opening of Congress in December 1922. This committee is vested with authority to get all the evidence in the subject which is to be studied and to make definite recommendations for proper coordination to the Senate and House from time to time. It is probable that the subject of a National Department of Public Works will be the first thing taken up and since the committee can bring in their recommendations in the form of resolutions or bills at any time, it is not contemplated that this investigation will in any way hold up the progress of the Public Works campaign. On the other hand it is distinctly a recognition of the engineers work; it shows just the attitude that the leaders of the Public Works movement have been trying to instill in the leaders of Congress, namely, that there is room for great improvement and that Congress should cooperate in a whole-hearted manner to bring this improvement about.

The Senate passed the measure by acclimation after speeches favoring it had been made by Senator Smoot, who is in immediate charge of the legislation for the majority. Senator Underwood, Democratic leader, also made a speech in favor of the resolution, in which he made the following statement: "I do not understand that it is introduced by way of criticism of anything which has taken place recently or in the distant past. The conflict for authority between the various bureaus of the Government and the duplication of work has not been deliberately done, but has grown up through a period of years. That there is a vast duplication of work in the Government, that there is lost motion and lack of economy cannot be questioned, and I think an effort should be made to avoid duplication and to work toward greater economy in the Government."

The 150,000-Volt Transmission Line of the Knoxville Power Company

BY THEODORE VARNEY

Aluminum Company of America, Pittsburgh, Pa.

AT a point on the Little Tennessee River a short distance above the mouth of the Cheoah River in North Carolina, the Knoxville Power Company has completed within the past year, the first portion of an extensive hydroelectric development. The ultimate development will require the tying together of a number of plants scattered over a large area and it was therefore necessary to choose powerhouse and transmission line equipment which would be best adapted to the entire system.

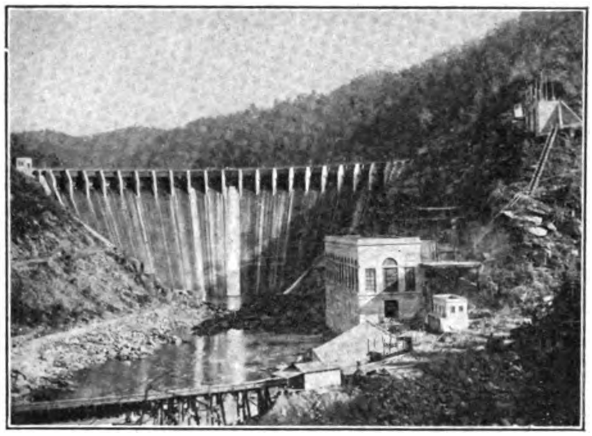
The initial development described herein might appear inconsistent if considered alone from the standpoint of voltage and length of line, but when regarded as an integral part of the larger scheme its characteristics become rational. For instance, the present line crosses a mountainous country, broken by river valleys and steep cliffs for about half its length, while the remaining distance lies over a fairly level plain. The rough ground necessitating a minimum number of supports required that a maximum amount of power be carried by each circuit and this in general means a high transmission voltage. It is probable that in choosing between a voltage of 110,000 and 150,000 the former would have sufficed for the present line, but as the complete development will involve lines of greater length, the higher voltage would have later become necessary and a uniform voltage for the system was considered essential.

Another point taken into account by the engineers who were responsible for the present design was that the trend or development is toward the use of higher voltages for transmission lines.

Still another consideration which made it advisable to provide for high efficiency, and consequently small losses, is the high load factor of the electrolytic process for which the system is primarily designed. Power for this purpose is valuable and interruptions are very expensive.

The electrolytic plant is located at Alcoa, Tennessee, formerly known as North Maryville, and its distance along the line from the present power house at Cheoah is 24.3 miles. At present one line only is completed between these points but ultimately another parallel line will be provided, and these will later be joined by additional lines supplied from other plants.

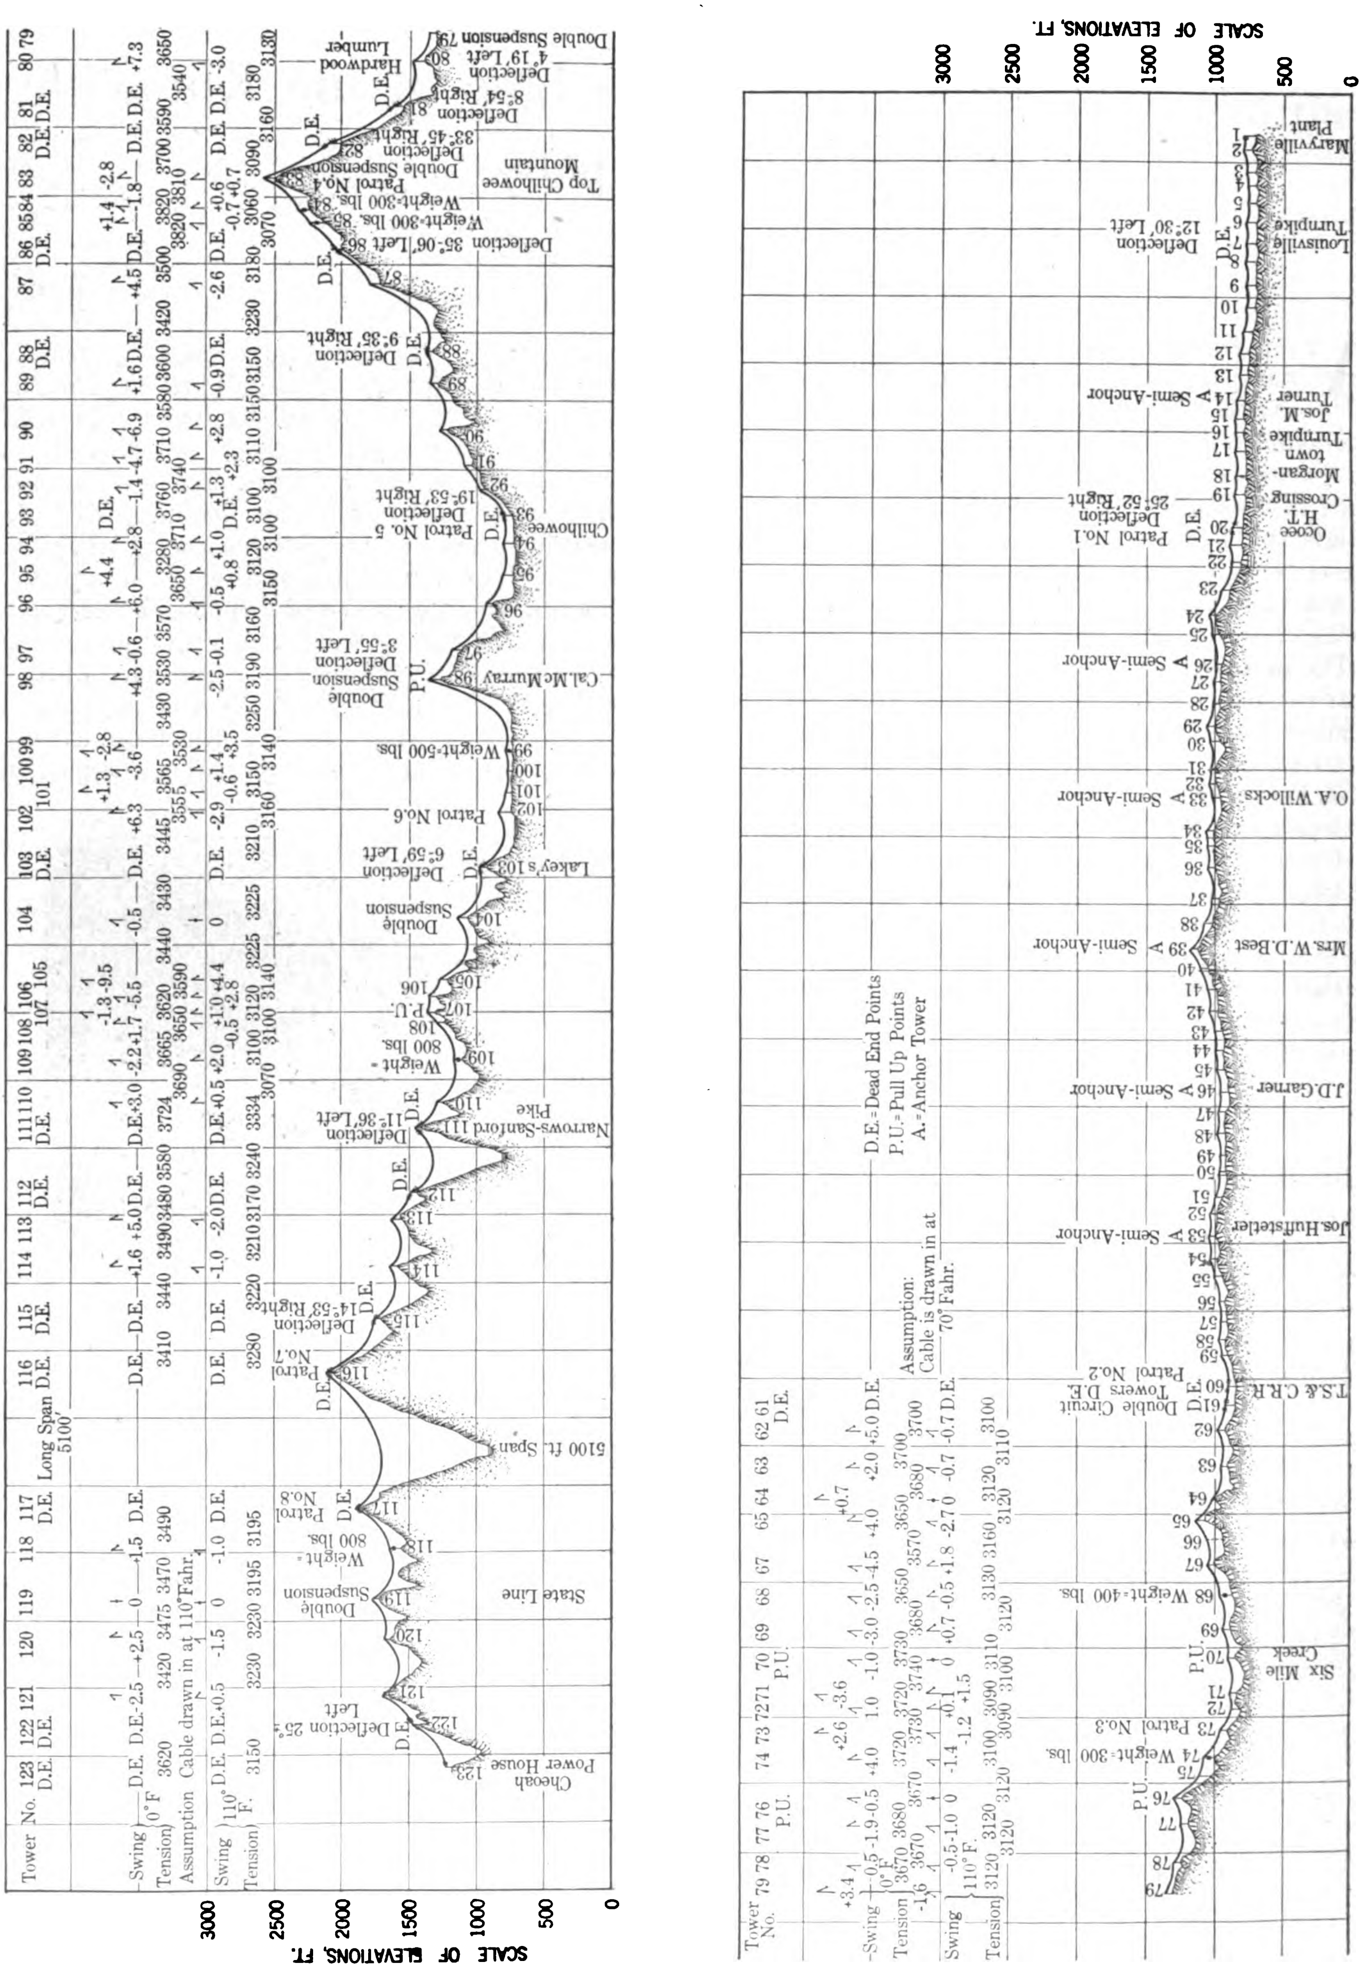
The broad scheme of development contemplated for the entire system is to operate it normally in units of about 50,000 h. p. so that the interruption due to a short circuit or other trouble anywhere on the system will not cause any disturbance or interruption outside of this group of 50,000 h. p. With this idea in view, the power houses contain no low-tension buses. Each of the generators (most of which will be about 20,000 kv-a. capacity) is served by a bank of transformers connected directly to it through low-tension switches, the high-tension side of the bank of transformers being connected to the high-tension bus through a set of oil switches. The high-tension bus at the powerhouses is sectionalized in such a manner that in normal operation a group of two of these generators with their transformer banks is connected to it and this group serves a transmission line, which terminates in a section of high-tension bus at the receiving end at Alcoa, which through step-down



DAM AND POWER HOUSE AT CHEOAH

transformers, serves an electrolytic load of about 50,000 h. p. The high-tension buses at the generating station and the high-tension buses at the receiving station are so arranged that they can be interconnected whenever emergency makes it necessary to run them in multiple, but it is intended that in normal operation the system shall be operated in units of about 50,000 h. p. consisting of a suitable amount of generating capacity and step-up transformers delivering power over an individual circuit to a suitable sectionalized load at the receiving end.

The right-of-way at the Alcoa end is 385 ft. wide and provides for four double-circuit tower lines. As the rough country is approached some of the lines branch off and the right-of-way narrows to 340 ft. to accommodate four single-circuit tower lines while still further along, the width is decreased to 200 ft. for the two



Profile of 150,000-Volt Line

remaining single circuit lines which will connect with the present plant at Cheoah. The right-of-way purchases include tree trimming rights fifty feet on each side and outside of the entire right-of-way. A telephone line on wood poles is provided for along each side of the right-of-way, one of which is at present completed.

The span lengths in the level country are fairly uniform and not over 800 ft., but in the mountains hardly any two spans are alike and several are over 2000 ft., while at one point where the line crosses the gorge of the Little Tennessee River, the span length is 5010 ft. The average span length for the entire line is more than 1200 ft.

The greatest altitude at any point in the line is about 2100 ft. and the corona is not, therefore, a serious item. However, on account of the high voltage, a considerable diameter for the conductor is desirable and it was furthermore necessary to use one having ample strength in order to meet the conditions imposed by the long spans and rough country. Accordingly, the conductor consists of aluminum reinforced with high grade steel which provides minimum weight with maximum strength. It was furthermore thought best to provide for carrying the entire load of the Cheoah power house on one line in case of emergency.

After the completion of the line and just before it was put into service in March, 1919, it was short-circuited at the powerhouse and current corresponding to 37-500 kw. and 75,000 kw. respectively, at 100 per cent power factor, was supplied at the receiving end from a steam turbine plant, with the following results.

Amps.	Volts.	Kw.	Frequency	Power Factor	Line loss
144	5160	330	60	25.6	0.885% of full load
288	9720	1230	60	25.4	1. 65% of double load

Temperature air at power-house 18.0 deg. cent.
Temperature air at receiving end 13.5 deg. cent.

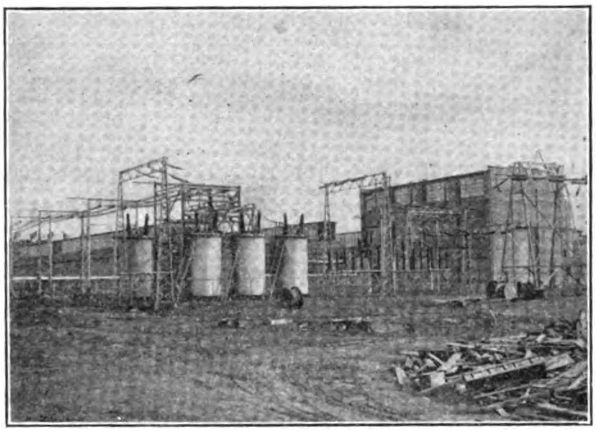
Hydraulic Plant

The dam of the present development is of reinforced concrete approximately 500 ft. long on its up-stream face, extending across the rocky gorge in the Great Smoky Mountains, through which the Little Tennessee winds its way westward to join the Big Tennessee. The crest of the dam is approximately 177 ft. above normal tail-water elevation, while by means of Taintor gates the pool level can be raised about 15 ft.

A tunnel about 540 ft. long driven through the rock in the left bank of the stream, discharges into a surge tank, also excavated in the rock, from which four tunnels lead sharply downward to the turbines in the powerhouse.

Power House

The power house which is constructed of reinforced concrete, approximately 216 ft. long, by 61½ ft. wide inside, provides for four generating units, of which three are installed at the present time. These are of the vertical-shaft type operating at a normal speed of 171½ rev. per min., and capable of delivering 20,000 kw. at 13,200 volts, three-phase, 60 cycles. Each feeds directly through a three-pole, 1200-ampere, automatic, inverse-time-limit, oil circuit breaker to a bank of three 7000-kv-a. single-phase, transformers stepping up to 150,000 volts. The high-tension side of these transformers are operated in star with neutral grounded and are connected to a high-tension bus, to which at present is connected through choke coils, one three-phase transmission line. Provision is made in the outgoing line for the future installation of a 150,000-volt oil cir-



Receiving Station at Alcoa, Tenn.

cuit breaker. Electrolytic lightning arresters are provided, and arc suppressors equipped with eight automatic fuses per phase are being installed.

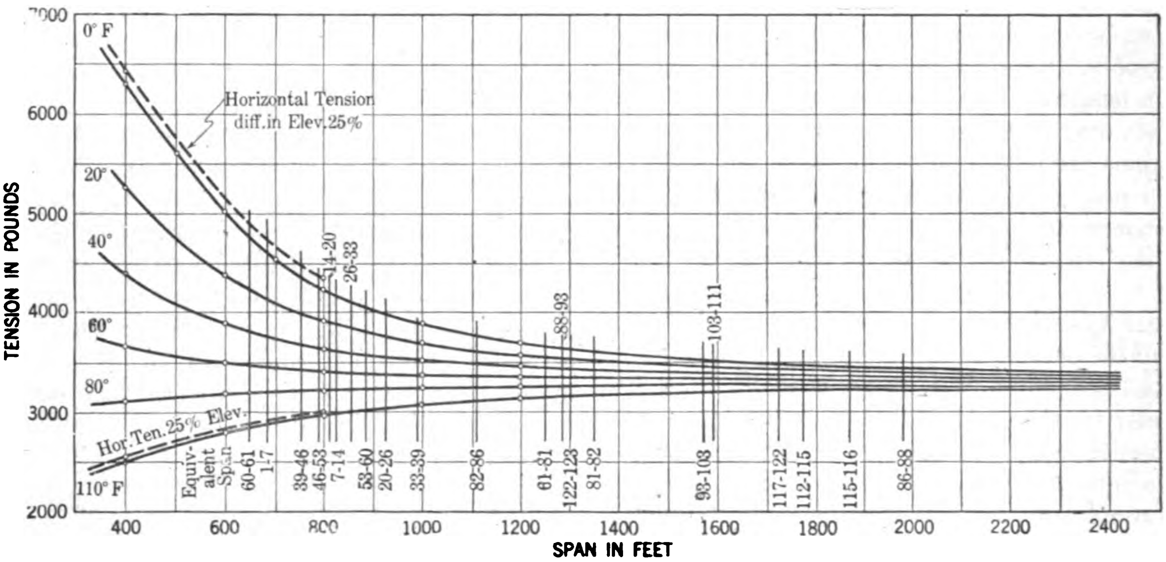
At Alcoa, the line connects directly through choke coils to a bank of three 14,000-kv-a. transformers, stepping down to 13,200 volts. Electrolytic lightning arresters are provided and provision is made for the future installation of an automatic oil circuit breaker on the line side. The low-tension side is connected through disconnecting switches and a 3000-ampere automatic oil circuit breaker to a 13,200-volt bus system to which are connected through disconnecting switches, oil breakers and transformers, twenty 2500-kw. synchronous converters. These converters deliver 500 volts d-c. to a 24-hour electrolytic load.

Transmission Line

The conductor decided upon is a 500,000-cir. mil aluminum cable, steel reinforced, the details of which are given with other data at the eud of this paper. The maximum tension in the conductor was not taken at the full elastic limit, but at 8000 pounds for the reason that in previous installations of somewhat similar character it had been found that greater tensions re-

quired a greater cost for tower construction and a preliminary investigation in the present case indicated this tension to be sufficient.

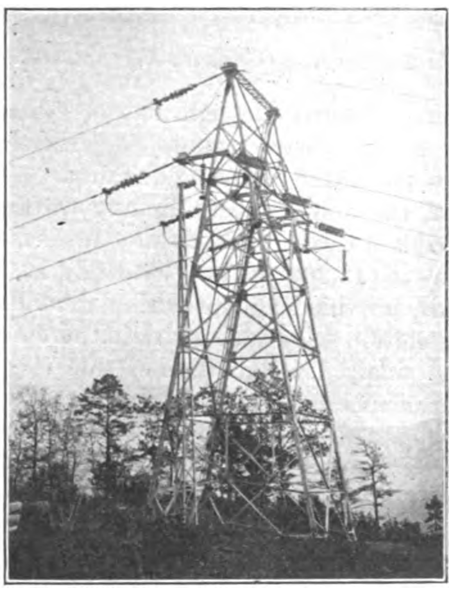
ice or wind was computed. This gave a value of approximately 3300 pounds. From this value the unloaded tensions for every 20 degrees from 0 to 110 were



Conductor Stringing Curves

It was assumed that this maximum tension would occur at 0 deg. fahr. with one-half inch of ice all around the conductor and a wind pressure of six pounds per square foot of projected surface of ice-covered cable.

By carefully studying the profile of the land the dead end and semi-anchor towers were located in such manner that the equivalent values of the spans between any

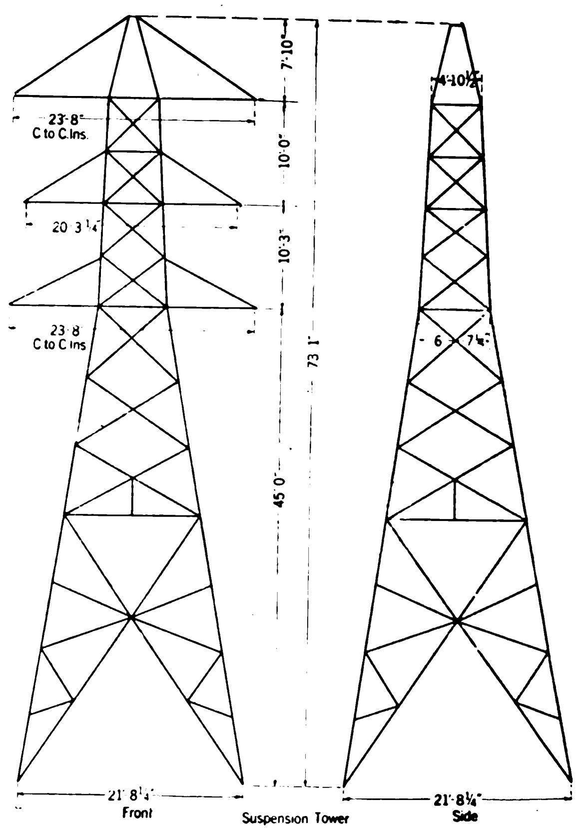


Long Span Anchor Tower

two anchor points, as referred to level supports, would not be very widely different. By this means the shortest equivalent span was found to be 650 ft. and the longest (exclusive of the 5010-ft. span which was treated separately) 2400 ft.

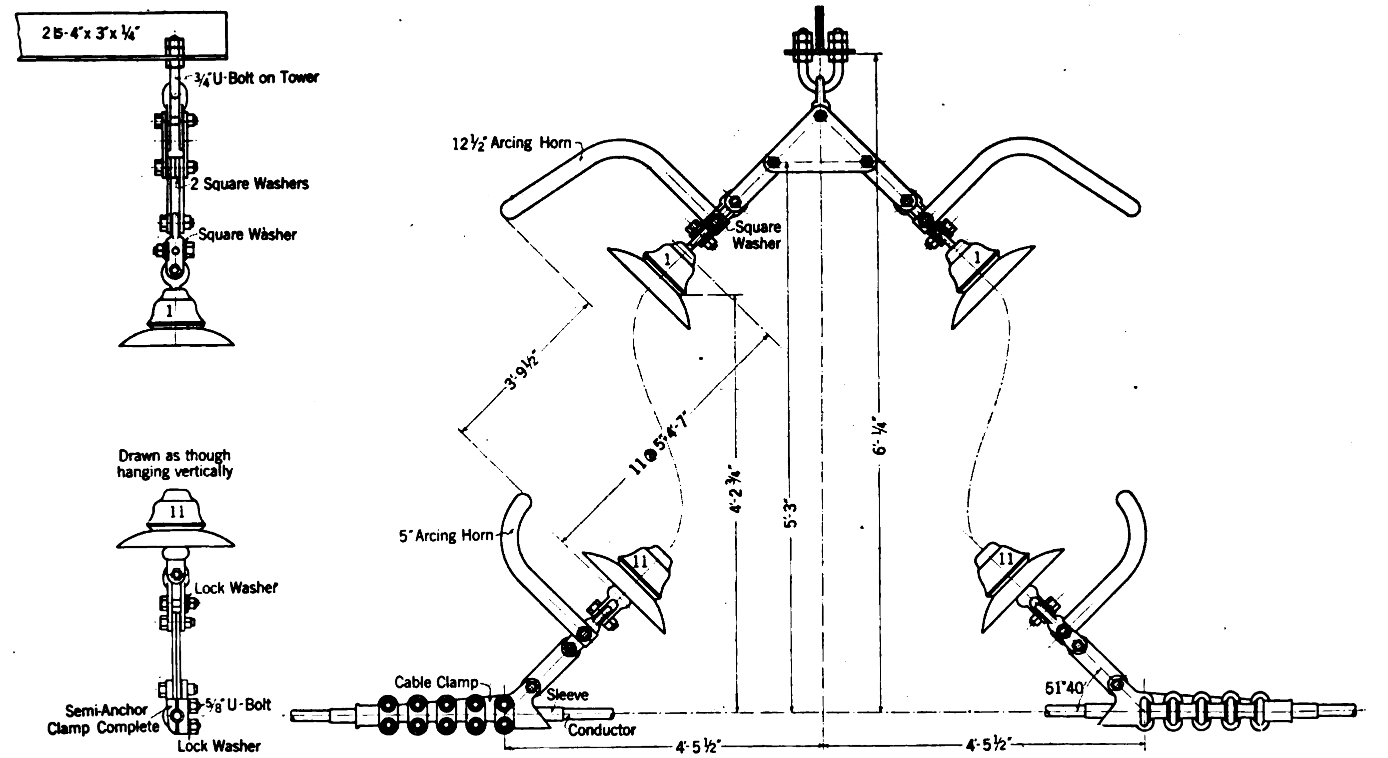
From the condition of maximum load in the shortest span, the tension corresponding to 70 deg. fahr, without

calculated for the ruling equivalent span for each of the consecutive dead end sections of the line. These curves are given in one of the illustrations. The equivalent



span numbers refer to the tower numbers in the profile, which is also illustrated.

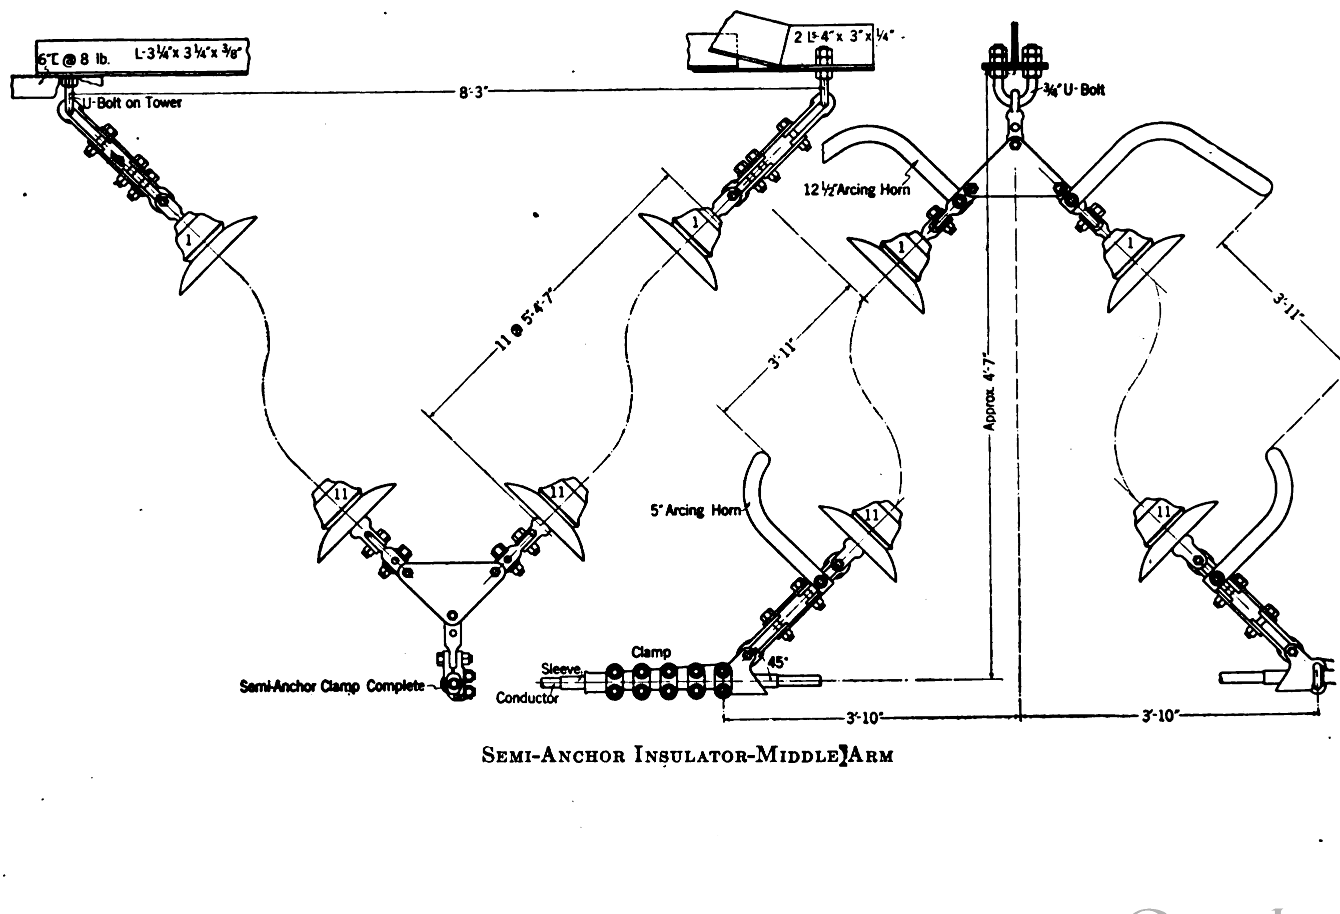
The cable was strung out through travelers and pulled up to the tension given in the curves corresponding to the stringing temperature. The insulator strings



SEMI-ANCHOR INSULATOR ASSEMBLY—TOP AND BOTTOM ARM

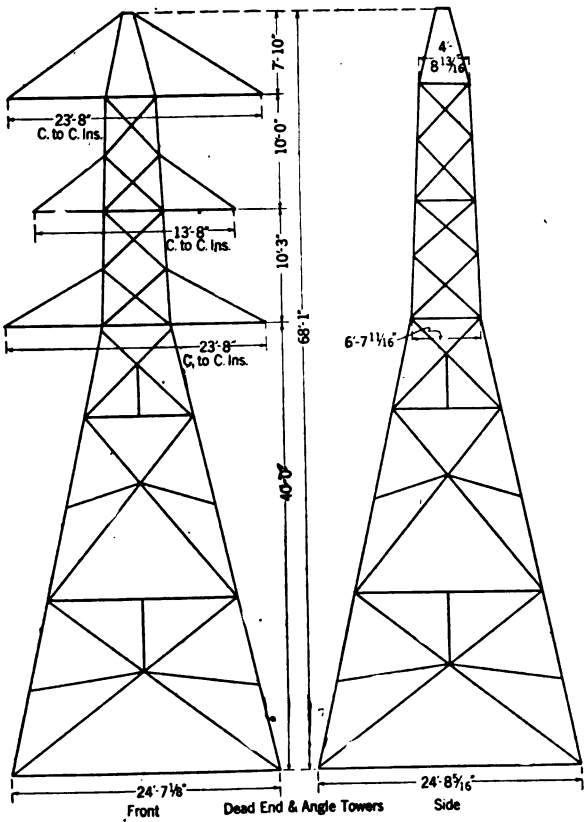
were hung vertically under these conditions but as the adjacent equivalent spans in each anchor section were not equal, any temperature changes produces a swing from the vertical in the insulator strings. A study was made of this condition and the position of the insulators was calculated for 0 deg. and 110 deg. fahr. The profile indicates the right and left swing of the insulators at the various towers in the rough country, corresponding to those extreme tempratures, assuming the strings to be vertical at 70 deg. fahr.

The towers were constructed of galvanized steel, delivered on the ground in sections and bolted together. As stated above the towers in the level country were double-circuited and in the mountains single. The illustrations indicate the several types of towers, together with the extensions used on rough ground as

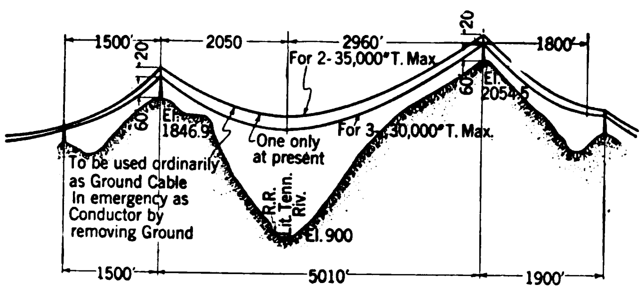


SEMI-ANCHOR INSULATOR-MIDDLE ARM

well as the anchors. The approximate weight of a double circuit suspension tower is 12,900 pounds and that of an anchor tower 13,200 pounds. The single circuit suspension tower weighs 11,200 pounds and the anchor tower 13,100 pounds.



Calculations were made of the side sway assuming wind pressures of 19 pounds per square foot on bare cables, and in order to provide proper clearance from the tower arms, brackets were provided to which the insulator strings are attached. These brackets, which

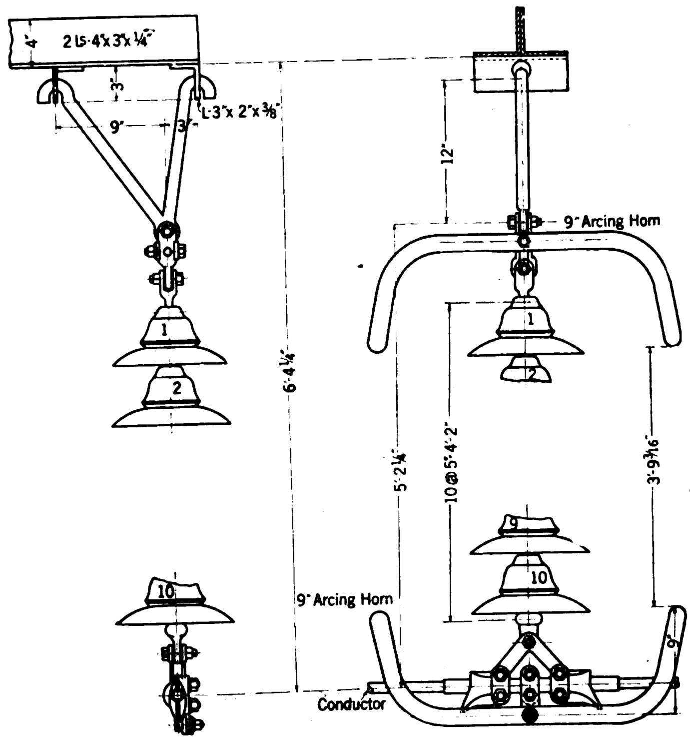


ELEVATIONS AT LONG SPAN

appear in the illustration, were hinged so as to prevent applying excessive torsional stresses to the bracket arms in case of a broken conductor.

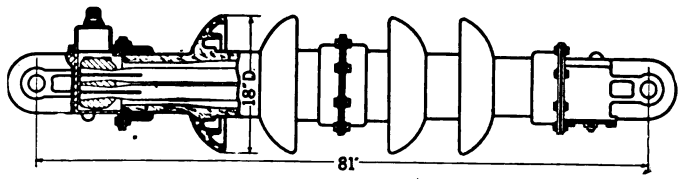
In addition at certain points where towers are located on side hills, the cable weight on the suspension strings is reduced in cold weather. While actual uplifts are provided against at these points, the tendency for side swing is increased and to overcome this, weights were attached to the insulator strings. This construction is shown in the illustrations and the towers where this construction was used are indicated on the profile.

Where the weight of unusually long spans has to be carried by suspension insulators the strings are doubled,



SUSPENSION INSULATOR ASSEMBLY
Top and bottom arm, two-circuit tower; all supports, one-circuit tower

while on the middle arms of the double-circuit towers double strings of insulators are used to prevent side sway and to enable a short arm to be used. This arrangement obviated placing all three phases in a vertical plane and enabled the bracing members of the



STRAIN INSULATOR AT LONG SPAN

tower to be reduced in weight, while still providing ample strength to resist torsional stresses due to a broken conductor.

At present one ground wire consisting of a ½-in. galvanized, high-strength, stranded steel cable is provided throughout the line except at the long span where special arrangement is provided as described later. Provision is made on the towers for adding a second ground wire if desired. The stringing tension for the ground wire was 2700 pounds at 70 deg. fahr.

One of the illustrations shows the relative elevation of the supports for the long span, compared to its length. The horizontal distance between supports is 5010 ft. while the difference in elevation is 208.5 ft.

The temperature at the time of stringing the cables was about 80 deg. fahr. and the three lower cables were strung with a sag of 237 ft. below the lower support, corresponding to a tension of 19,000 pounds per cable. The upper cable was installed with a sag of 216 ft. below its lower support and with a tension of 20,400 pounds. The horizontal separation between the lower conductors is 20 ft. and the upper cable is 20 ft. above the lower three at the points of support.

One of the long span towers, marked *W* in the illustration weighs 55,000 pounds and the other *W W* weighs 57,000 pounds.

In these spans the steel core of each cable carries the entire load and the cores are socketed with zinc into open forged steel bridge sockets which are attached directly to the strain insulators. The aluminum part of the cable is cut off in advance of the sockets and connection is made by means of an aluminum parallel groove clamp and jumper connection to the other side of the tower.

Each cable is provided at each tower with a single 150,000-volt, oil filled, porcelain covered, wood strain insulator. In deciding to use this type of insulator the engineers were guided by the previous satisfactory performance of similar insulators on a 110,000-volt river crossing belonging to the Tennessee Power Company. Very careful and complete tests were made of the insulators before installing, and in order to provide a spare part in case of a strain insulator breakdown the upper conductor of the long span was arranged to be normally grounded, thus replacing the standard ground wire. A busbar arrangement is provided so that this conductor may be substituted for anyone of the three conductors, which may then be grounded and repaired. One of the cuts illustrates the construction of the strain insulators.

This span, which is understood to be at present the longest single conductor span in the world, involved cable lengths too heavy to be readily transported to either tower and consequently a rather ingenious scheme was employed for installing them. They were wound at the factory on special reels having a partition which divided the total amount of the cable into two parts, each of proper length to reach from the railroad at the bottom of the gorge to one of the towers.

The reel was set up beside the railroad track and a portion of the long section pulled out first. When the portion of this section still remaining on the reel equalled the short section, the latter was started out. The ends arrived at the towers at the same time and the loop was removed from the partition in the reel without damage or splicing. The cables were pulled to tension with a donkey engine.

There are eight patrol stations provided along the telephone line on the right of way. The location of each is indicated on the profile. Two patrolmen are constantly employed. One covers the line from Alcoa to Patrol Station No. 4 at Tower No. 83, while the other inspects the line from Tower No. 83 to the Cheoah Power House.

The latter covers the rough country from Cheoah to Patrol Station No. 7 at Tower No. 111 on foot and over the balance of the distance to Tower No. 83 he rides horse-back. Each patrolman goes over the line once every week and in addition makes an inspection after any storm or lightning interference.

CONDUCTOR

The conductor consists of aluminum cable steel reinforced composed of a double galvanized extra high strength steel core, overlaid with strands of hard drawn aluminum.

The elastic limit and ultimate strength of the aluminum strands are respectively 14,000 and 24,000 pounds per square inch.

The corresponding values for the steel core are 130,000 and 160,000 pounds per square inch. The elastic limit and ultimate strength of the complete cable is taken as the sum of the corresponding values for the individual strands.

The modulus of elasticity of the aluminum portion of the cable is taken at 9,000,000 pounds per square inch and of the steel portion 30,000,000 pounds per square inch.

The characteristics of the conductors are as follows:

Standard Conductor	
Steel	19 x 0.0775 in.
Aluminum	30 x 0.1291 in.
Diameter complete cable	0.904 in.
Weight per foot complete cable	0.776 lb.
Elastic limit complete cable	17140 lb.
Ultimate strength complete cable	23750 lb.
Weight of ice per foot (½ in. thick)	0.859 lb.
Wind pressure per foot (6 lb. square ft. over ice)	0.952 lb.
Resultant, loaded weight per foot	1.892 lb.
Wind pressure per foot (19 lb. square ft. on bare cable)	1.43 lb.
Resultant, loaded, weight per foot	1.625 lb.
Virtual coefficient of expansion per deg. fahr	0.00001003
Virtual modulus of elasticity	12,900,000 lb.
Long Span Conductor	
Steel	61 x 0.097 in.
Aluminum	22 x 0.150 in.
Diameter complete cable	1.175 in.
Weight per foot complete cable	2.032 lb.
Elastic limit complete cable	65,000 lb.
Elastic limit steel portion	59,000 lb.
Ultimate strength complete cable	82,000 lb.
Ultimate strength steel portion	73,000. lb.
Weight of ice per foot (½ in. thick)	1.025 lb.
Wind pressure per foot (6 lb. sq. ft. over ice)	1.085 lb.
Resultant, loaded weight per foot	3.25 lb.
Wind pressure per foot (19 lb. sq. ft. on bare cable)	1.86 lb.
Resultant, loaded, weight per foot	2.75 lb.
Virtual coefficient of expansion per deg. fahr	0.0000077
Virtual modulus of elasticity	20,200,000 lb.

INSULATORS

It was realized that carefully selected porcelain with working mechanical tensions limited to safe values would be necessary to insure successful operation and, accordingly, the following points were covered by the specifications when the standard suspension and anchor insulator units were purchased:

Porcelain bodies to be non-absorbent, thoroughly vitrified, free from cracks, etc., and surfaces in contact with cement to be unglazed.

Caps to be of galvanized malleable iron of minimum ultimate strength of 30,000 pounds per square inch and designed for a maximum stress of 12,000 pounds per square inch at 9500 pounds total load.

Pins to be of soft steel drop forgings designed for a maximum stress of 35,000 pounds per square inch at 9500 pounds total load.

Parts to be cemented together with slow setting neat Portland cement of best quality.

Porcelain parts taken from kiln to be subjected to dry flash-over test for five minutes. Five days after cementing and before six days, units to be subjected to 3500 pounds load for five minutes. Units to show puncture voltage under oil of at least 120 per cent of dry flash-over voltage. Ultimate tensile strength of complete unit to be not less than 8500 pounds. Resistance of units to be infinite when tested with 1000-volt, 2000 megohm megger. Standard A. I. E. E. wet flash-over test for complete string of ten units to be not less than 390,000 volts at 60 cycles.

For the long span strain insulators the following points were covered by the specifications;

Tension members to consist of selected hickory and be able to stand before assembly a tension test of 25,000 pounds for one-half minute, also a dry flash-over test of 520,000 volts.

End castings before assembly to be able to stand a load of 75,000 pounds.

Complete insulator to stand load of 35,000 pounds for one-half minute, a temperature of 140 degrees fahrenheit for five hours without leakage of oil and after cooling a test of 520,000 volts.

Power was first turned on this line April 16th, 1919, and to date (February 1920) no interruptions due to any defects of the line have occurred.

The writer is indebted to Messrs. William Hoopes, T. J. Bostwick, I. G. Calderwood, L. W. Henry and B. F. Grote for the data included in this paper.

ARMY PAY BILL AFFECTS SOME CIVILIAN ENGINEERS

When the Army Pay Bill was made law, it carried a provision whereby some of the officers of the Coast & Geodetic Survey are to receive the same pay and allowance as prescribed for officers of the Navy with whom they hold relative rank, as prescribed under act of May 22, 1917, the provisions of which were made to apply to officers of the Coast and Geodetic Survey. The bill which recently became law provides for the personnel of the Army, Navy, Marine Corps, Coast & Geodetic Survey, Public Health Service and the Coast Guard.

Actual increase in compensation ranges from about $720 to $2,700 in the various grades, which includes all the allowances granted by the bill. The officers in the Coast & Geodetic Survey feel that this is a remarkable recognition of civil engineers of the Government, and it is contemplated that it will enable them to fill up many vacant positions in that service, as a result of which, they will be able to more nearly carry out their program in the development of magnetic surveys, traverse and leveling, precise and secondary triangulation. In this connection it is interesting to note that about forty vacancies now exist in the lower grades in the officered personnel, due to the fact that civil engineering graduates have not been attracted by the old pay. The entrance salary will now be slightly in excess of $2000, which will attract more civil engineering graduates to this service.

In addition to the possibility of improved conditions in personnel of the Coast and Geodetic Survey, it is probable that the Sundry Civil Bill has passed by the House will finally contain an item for magnetic and geodetic surveys in Alaska appropriating $147,000. About $28,000 of this sum will be devoted to the magnetic surveys of the country and the balance will be expended on precise and secondary triangulation, traverse and leveling. This appropriation is the same as was available for the fiscal year 1920, except that last year's appropriation was made up of a regular appropriation of $100,000 plus a deficiency appropriation of $47,100. This compares with $90,000 available in 1919, and represents an increase of 63 per cent over the period of two years. Officers of the Coast and Geodetic Survey have expressed the opinion, however, that even with this substantial increase, there is not as much money available as will be needed in order to carry the control surveys well ahead of the detailed topographic mapping program.

Factors Controlling the Design and Selection of Suspension Insulators

BY W. D. A. PEASLEE

Electrical Engineer, Jeffery-Dewitt Insulator Co.

A discussion of the factors entering into the design and operating behavior of suspension insulators and the problems to be solved in designing a suspension insulator to overcome the objectionable features shown by experience to affect seriously the operation of the insulators in service.

Factors to be taken into consideration in the selection of suspension insulators for a given condition are given and a brief discussion of the general trend of future improvements is presented.

Introduction

IN the early days of electrical distribution of power the insulator problem was unimportant. The insulator gave more satisfactory service than the rest of the apparatus essential to the generation and distribution systems. As long as the voltages were low the dielectric field distribution was of relatively small importance. As the transmission distances and therefore the economic transmission line voltages increased the insulator problem became more acute. The first attempt to meet the insulation requirements of these higher voltage lines was an increase in the physical dimensions of the lower voltage type of unit. No attention was given at this time to the distribution of the dielectric field or its shape although the laws governing the dielectric flux distribution in such cases were well-known.

As a result with the increased voltages came an increasing amount of insulator trouble until when the transmission voltage passed the 30,000 volt mark, the insulator problem became of greatest importance. Improvement in design through rational study of the problems had brought the reliability of other parts of the transmission and generating systems to a very satisfactory point. The insulator, however, had not made a corresponding advance and failures were encountered at a rate that for a time threatened the success of high-voltage transmission of electrical energy.

The attention of the insulator manufacturers was turned at once to the problem and many new designs were brought out as suggested remedies for this situation. Practically none of these was based on a rational study of the insulator as a dielectric problem, most of the improvements being made from the narrow standpoint of the small experience then available. The problem was attacked by manufacturers and research men of the country, but unfortunately from widely different points of view. The manufacturers being limited by manufacturing difficulties and the great cost of a radical change in methods, clung to small changes in existing forms and processes, while the research man attacked the problem from a scientific standpoint, based on a careful study of the dielectric and mechanical problems involved, but too often handicapped by a lack of knowledge of manufacturing processes and their limitations. For these reasons many excellent ideas coming from both sources were laid aside from lack of coordination of the two lines of study.

In the early insulator types, at times the flash-over distance was much greater than warranted by the thickness of dielectric and many failures by electric puncture were encountered, also the design was such that corona was formed at different places on the insulator at low voltages.

Gradual improvements in the design eliminated many of these objectionable features one by one, and improvements in manufacturing methods brought forth constantly improving grades of porcelain.

When the pin type insulator reached a limit set by size, weight and cost, the suspension type unit was introduced. This was a decided step forward in insulator practise, but unfortunately the designers of the suspension type unit still neglected a thorough consideration of the dielectric field of flux in the designing of their units, making them simply mechanical modifications of the existing types.

Thus a great many faults of the early pin type insulators were repeated in the first suspension units. Due to its small size the flash-over voltage of the suspension unit was practically always below the puncture voltage, though, as will be shown later, the margin was not sufficient, and, with the introduction of the electric tests on assembled units in the factory, very few direct puncture failures were encountered when the insulators were first placed on the line.

At this point, however, a type of failure appeared which may be classified as a deterioration failure, the insulator passing successfully severe factory tests, but failing after a period of service on a transmission line under conditions less severe than those successfully resisted in the course of factory testing.

The study and analysis of this problem has filled the pages of engineering literature during the past ten years and many divergent theories regarding the causes of and remedies for the various types of failure have been advanced. At the present time insulators successfully passing factory tests deteriorate in service at rates varying up to 20 per cent per year. As stated by a prominent transmission engineer quite recently:

"All insulators at present on the market seem to be

To be presented at the Pacific Coast Convention, Portland, Ore., July 21-23, 1920.

subject to a steady depreciation that is too large to be ignored or accepted as an operating necessity."

The conventional type suspension insulator unit, and also, to some extent, the multi-shell pin type unit, seem in general to be subjected to the types of failures indicated in the following table:

MECHANICAL FAILURES

a. Due to the use of materials having widely different coefficients of cubical expansion as in conventional cap and pin construction which causes enormous stress under temperature changes.

b. Due to mechanical overloading.

c. Due to shocks as shooting.

d. Due to lightning and power arcs.

ELECTRICAL FAILURES

a. Actual electrical puncture.

b. Leakage under adverse conditions followed by flash-over and heavy power arc.

c. Due to porosity.

In the conventional type of insulator three materials, porcelain, cement and steel, are tightly compressed in contact in an unyielding fashion. These materials have different coefficients of cubical expansion and the temperature variations, in many cases quite abrupt, met with in operation, seem to set up internal stresses which crack the porcelain, leading to electrical failure. Further the cement itself is subject to volumetric changes somewhat of cyclic nature and also of a crystalline growth character that contribute to these phenomena. Prominent engineers have expressed the opinion that 85 per cent of the failures of insulators of this type were preceded by mechanical failures of this class. The sun striking upon insulators on a frosty morning has in many cases been the signal for some rather startling exhibitions of such failures. In connection with this, the internal stresses existing in the porcelain parts due to improper manufacturing methods and firing, have doubtless contributed to this condition. That the manufacturers recognize this weakness is well shown by the elaborate precautions that have been taken to reduce this effect through the medium of felt washers, lead thimbles, etc., appearing more recently in their designs.

That the transmission engineers of the country have realized the importance of the deterioration type of failure is indicated by the extensive study, which has been made of the various methods of testing employed by most engineers responsible for large transmission systems today, such as the megger and buzz stick methods. Reliance is placed on these methods, to detect the beginning of this deterioration permitting the removal of the affected insulator before it has dangerously weakened the string. Many engineers are also advocating the deliberate addition of several units to an insulator string above the number required for actual insulation purposes as an insurance against this deterioration regarded by them as inevitable.

Failures due to mechanical overloading are rare in modern lines as the lines are usually designed with proper consideration of extreme loading conditions and ample mechanical safety factors. The same remark may be applied to failures from shock and shooting, and although at one time about the most popular outdoor sport, in certain localities, for irresponsible people, was the shooting off of the power company's insulators, fortunately, this condition is no longer of very great importance. The failures due to lightning and power arcs are, however, at the present time rather large. It is doubtful if we could define exactly what might be considered a direct stroke of lightning, and probably such strokes on transmission lines are rather rare. Lightning flash-over of an insulator string is usually in itself rather harmless, but the power arc that follows the static flash-over is extremely destructive to any but the most substantial types of insulator. The thinness of the porcelain part of the conventional type insulators, combined with the abrupt changes in form and surface directions renders them susceptible to destruction under the action of the intense heat of such an arc. Any insulator with thin petticoats is very likely to be considerably damaged by power arcs as the temperatures and the mechanical stresses involved are very high. The chief requisite for an insulator in this regard is strength, gradually increasing thickness from the edge of the skirt inwards, and a high thermal capacity. Insulators so designed will successfully resist severe power arcs and lightning surges, especially when the system is equipped with the proper kinds and numbers of relays, to a remarkable degree.

An actual electric puncture is probably rare on any modern insulator that has been properly fired, most electrical failures being the result of previous mechanical failures.

Leakage is a problem that is to a large extent dependent upon localities and specific conditions. Smelter fumes, salt fogs, dust storms and many other causes tend to make the leakage effect vary and it has been generally conceded that in bad localities the only remedy is a periodic cleaning of the insulators. A few extra units added to a string will postpone the inevitable cleaning, but it is probably safe to say that under bad conditions no insulator string could be used commercially that would not require cleaning after a time. In connection with this, however, as leakage always culminates in a flash-over, it is important that the insulator be able to withstand power arcs, especially in regions subject to bad leakage conditions.

Porous porcelain absorbs moisture from the atmosphere, thereby decreasing its electrical resistance. The leakage current flowing through the porcelain under electrical stress tends to heat localized portions to a very high temperature. This local heating causes mechanical failure followed by the passage of a power arc through the porcelain, or due to the negative temperature coefficient of electrical resistance of porcelain, the leakage current may under certain conditions gradually increase with a concomitant increase of temperature, this action being cumulative until the porcelain is punctured. A good many instances of failure

of this kind both in laboratories and under field conditions have been encountered. Good glazing postpones the deterioration of porous porcelain but cannot eliminate it.

Until recently the progress in the manufacture of suspension type insulators has been rather largely along certain detailed attempts at the improvement of certain specific faults such as the utilization of felt washers, lead thimbles, etc. in the conventional cap and pin type design. The problem had not been attacked from a sufficiently scientific standpoint and there is still great need of a scientific study of this problem based on an analysis of the dielectric field of flux around insulator strings, and the electrical and mechanical requirements of the units in relation to the limitations imposed by ceramic and manufacturing conditions.

The following discussion of the analytical and experimental work undertaken along this line from the electrical and ceramic standpoint, the progress that has been made and the results that have been secured in the form of rationally designed insulators will, it is hoped, be of some interest to the operating engineer and stimulate further study and advance in this vital subject.

Factors Governing Rational Insulator Design

The requirements to be met in the design of suspension insulators may be broadly classed under two headings:

1. The insulator must support the line mechanically with adequate safety factors under the most adverse conditions.
2. The insulator must insulate the line with adequate safety factors under any electrical conditions not rendering other apparatus on the line inoperative.

It is obvious that any suspension insulator must be designed in the form of a unit that will meet widely divergent conditions. That is, from the manufacturing standpoint it is inadvisable to manufacture units of different mechanical strengths for different weights of conductors and climatic loadings. The design hinges then upon a unit that in the heaviest lines considered under the most adverse conditions of loading will give an adequate safety factor and will yet be cheap enough to be used on the less important lines.

The insulation afforded is obtained by building up strings of different lengths, but it is hardly advisable to attempt to insulate a line at great expense to withstand almost infinite voltages when, due to the limitations of other apparatus connected to the line, the system will be inoperative under extreme over-voltage conditions.

A study of existing lines and the probable limitations in conductor sizes and tower spacing of lines from 150,000 volts down, indicate that a mechanical strength of from 9000 to 10,000 pounds is adequate for a suspension unit, provided the unit is so designed that repeated stressing does not injure the unit electrically. The rational design herein discussed is, therefore, based on this mechanical strength requirement. The amount of discussion that has taken place recently regarding the use of porcelain in compression and tension makes it advisable at this point to discuss this matter a little in detail. The mechanical strength of ordinary porcelain in tension is in the neighborhood of 1500 lb. per sq. in., while the compressive strength is around 40,000 lb. in a porcelain having reasonable dielectric and temperature change resisting qualities. On account of the wide differences in these two figures many engineers have been dubious of the advisability of using porcelain in tension. The same argument might be used against the employment of cast iron in tension, and yet, although having very largely the same mechanical characteristics as porcelain, cast iron is consistently used in tension in the design of machines and structural members. As long as the unit stresses in the material are kept below the ultimate strength of the material with due regard to adequate safety factors, there is no rational objection to the employment of porcelain in tension any more than there is to a corresponding utilization of cast iron.

Insulator Shape as Affected by the Dielectric Field of Force

The dielectric field of force between similar electrodes is in general an ellipsoid of revolution though this is not strictly true, except between electrodes which are confocal hyperboloids of revolution, and no insulator electrodes are of this form. The agreement of the dielectric field with the ellipsoid is only approximate. However, the insulator should in general be symmetrical and conform as far as possible to the shape of the dielectric field. The placing of dielectrics of different specific inductive capacitances in series should be avoided, and therefore, the surface of the insulator should follow as closely as possible the lines of force in the field. In general the equipotential planes between the insulator electrodes should intersect for equal increments of potential, equal zone widths on the insulator surface. In connection with this point it is interesting to study Fig. 1. In this figure it will be noted that the conventional type unit does not conform to this requirement and the result of this lack of conformity is the appearance of corona on the unit at relatively low voltages, the corona appearing first where the equipotential planes are closest together. The requirement of a symmetrical shape introduces at once the problem of attaching the hardware to the porcelain in a different manner from that employed in the conventional insulator type. At the same time it becomes necessary to develop some form of hardware that will eliminate the terrific stresses imposed by the conventional type of hardware as previously discussed. Furthermore, in addition to the above requirements a large thermal capacity is

necessary in a unit to enable it to resist power arcs and this demands a rather massive porcelain structure.

The design of the hardware presents a further difficulty that is solved only by a compromise between ease of assembly and security of the connection against actual failure or uncoupling. Furthermore, the hardware and shape design of the porcelain structure must be such as to resist to the greatest possible degree abrupt temperature changes.

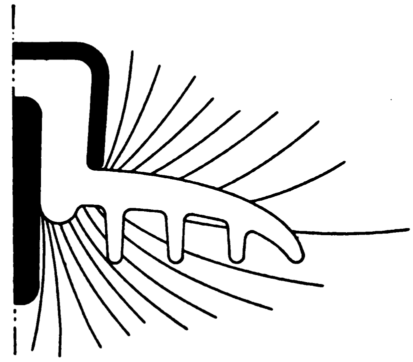


FIG. 1-a—POTENTIAL DISTRIBUTION ON THE SURFACE OF CONVENTIONAL INSULATOR, INDICATED BY THE INTERSECTION OF THE INSULATOR SURFACE WITH THE TRACES OF THE EQUIPOTENTIAL SURFACES

The voltage intervals between equipotential surfaces are equal.

DEVELOPMENT OF A RATIONALLY DESIGNED SUSPENSION INSULATOR

It is not generally appreciated by the high-tension engineers of the country that the electrical duty of the end unit is the basis of rational suspension insulator designs. Fig. 2 gives the distribution of voltage on the units of a string of suspension insulators, and it will be noticed that the conductor unit is carrying by far the greater proportion of the voltage stress. This unit is, therefore, the key to the design as, if it is so designed as to be safe, the rest of the units are obviously well within safe limits of engineering practise. The curves of Fig. 3 may be of interest, giving the percentage of the total voltage across an insulator string that is carried by the line and tower units respectively.

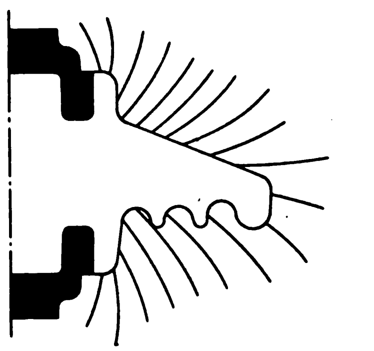

FIG. 1-b—POTENTIAL DISTRIBUTION ON THE SURFACE OF RATIONAL SUSPENSION INSULATOR, INDICATED BY THE INTERSECTION OF THE INSULATOR SURFACE WITH THE TRACES OF THE EQUIPOTENTIAL SURFACES.

The voltage intervals between equipotential surfaces are equal.

These figures bring out to a marked extent the advantage of a proper distribution of the equipotential planes as previously discussed in that such distribution produces a unit in which the corona voltage is very high. The reason for this unequal distribution of voltage has been discussed in engineering literature of recent years and will not be commented on here. In this connection, however, Fig. 4 is illuminating in the light that it sheds upon the distribution of the equipotential planes on an insulator string. This method of illustration is most graphic in showing the actual physical conditions surrounding an insulator string under operating conditions.

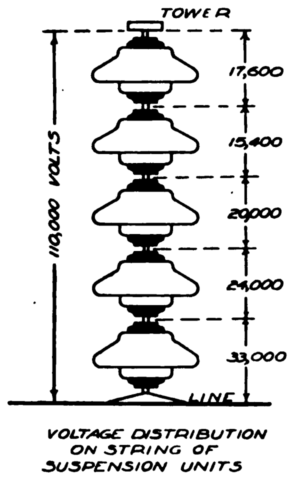

FIG. 2

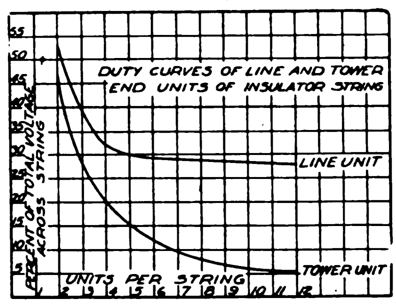

FIG. 3

Referring again to Fig. 2, it is seen that under the conditions given with a five-unit string on a 110,000-volt delta-connected line (conditions which are being successfully met at the present time by the rational design under discussion), the conductor unit is subjected to a normal-frequency voltage of 33,000 volts. The maximum high-frequency transient that has been reported by writers and investigators as likely to be met with high-tension transmission lines is around 100,000 volts. It has been shown that the effect of the normal and high-frequency voltages combined in a circuit is to produce stresses which are the arithmetical sums of the normal and high-frequency voltages. This is readily understood as according to the law of probability, the high-frequency and normal voltage peaks will coincide in time relation a certain

percentage of the time. The very high time-lag of such highly damped high-frequency transients as are encountered on transmission lines, renders possible the application of such combined voltage stresses to an insulator without flashing it over. In other words,

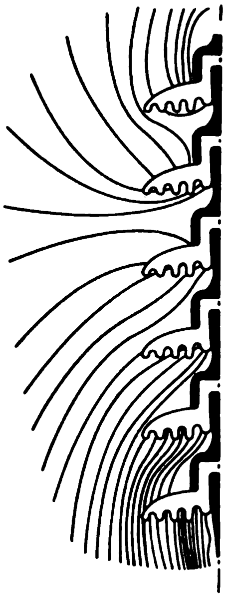

Fig. 4—Distribution of Potential Across String of Insulators

Taken from "Distribution of Potential about High Voltage Insulators—Alcutt and Skolfield, *Journal of Electricity*—June 17, 1916.

the line unit in Fig. 2 might have impressed upon it a total stress of 133,000 volts and though the flash-over voltage of the unit is 100,000 volts this unit would not flash over under these conditions due to the large time-lag just mentioned. As insulators should operate with an adequate safety factor, it is obvious that under such conditions a puncture value of around 300,000 volts at 60 cycles is necessary. In other words the puncture voltage of a rationally designed suspension unit should be in the neighborhood of three times the dry flash-over voltage at normal frequency and this is the fundamental basis of the design of rational suspension insulator units.

While leakage is a question very largely hinging upon particular climatic or other conditions a rational shaped design has been found to improve the ability of a given length of surface leakage path to limit the leakage current. Instances are known of ideal shape designs wherein the flash-over of the insulator was the same when previously cleaned, as when covered with a considerable coating of dust. This, of course, is an extreme condition but the fact remains, and has been demonstrated in the laboratory, that proper surface shape is much more efficient in this respect than surfaces wherein the divergence from the direction of the lines of force is marked. The length of the leakage path of a suspension type insulator is rather limited. The units are 10 in. (25.4 cm) or 11 in. (27.9 cm) in diameter, and if many thin petticoats are added to the unit to increase the leakage distance they are rendered much more susceptible to destruction by power arcs on account of the thin porcelain necessarily involved.

Porous porcelain is undoubtedly the cause of a great deal of insulator depreciation. One large insulator manufacturer has recently made the published statement that non-porous porcelain could not be made, stating, "a low moisture absorption is desirable, but it must not be assumed that any satisfactory porcelain can be made which will have zero absorption." This statement is absolutely challenged. One of the first objections to a rational insulator design was made by ceramic people who stated some years ago to the author that there was no doubt that such a design was desirable but that it was impossible to make a porcelain insulator of the shape, volume and thickness necessary without having it very porous. After a great deal of factory and laboratory research this problem has been solved and insulators can be made in practically any size or shape of absolutely non-porous porcelain as determined either by the psychometer or impregnation tests. This matter will be further discussed later in the paper.

It is well-known that the efficiency of an insulator string is a function of the ratio of the capacitance of the metallic interconnecting parts between the disks to ground to the capacitance of the insulator itself as a condenser and that the string efficiency is improved as this ratio decreases in numerical value. This point must be carefully considered in any rational design and hardware with a large surface between the units avoided as much as possible.

The advisability of a high impulse ratio has been admitted only quite recently by engineers in general,

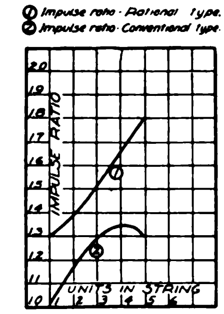

Fig. 5

and this feature is of importance because the impulse ratio is a measure of the ability of the insulator system to withstand lightning frequency flash-over. The impulse ratio of a unit and of the string built up from such units is a very important feature of insulator design, and one which has not received the attention that it should have received from most manufacturers.

The voltage at which corona appears on a unit is of great importance as a reference to Fig. 2 will show, and it is important to have this corona-forming voltage as high as possible. On a rationally designed insulator this voltage should be considerably above 30,000 volts while in many conventional type insulators at

present on the market corona appears rather decidedly at voltages from 12,000 to 16,000 volts. Fortunately the conditions necessary for the attainment of the above features of insulators influences in the right direction the value of voltage at which corona will appear on the unit. Many lines are in operation with

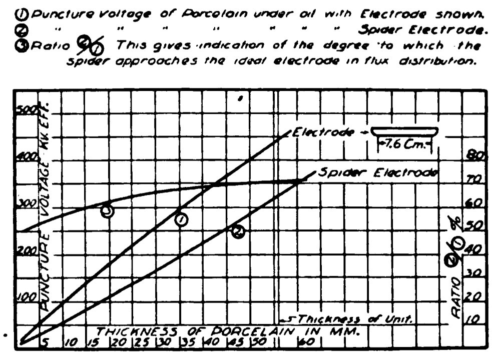

Fig. 6

conventional type units wherein additional units have been added above the actual insulation requirements of the line to insure the operation of the string without corona on the conductor unit.

The conditions discussed in general require conflicting features of design and render the design of any insulator more or less of a compromise, and the skill of the insulator designer is tested in producing the particular compromise giving the best solution under the limitations of ceramic and manufacturing possibilities. The following brief description of some of the experimental work undertaken in the research laboratories of Jeffery-Dewitt Insulator Company in the study of

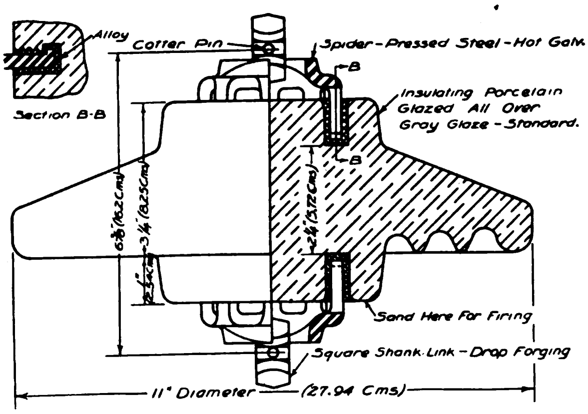

Fig. 7

the design and manufacture of suspension insulators may be of interest in showing something of the amount of work involved in such studies and something of the tendency and possibilities of future development.

Determination of the Thickness of the Dielectric Between Electrodes

As previously discussed the puncture voltage of the high-tension insulator should be approximately three times the dry flash-over voltage. Having given then an acceptable dry flash-over voltage and mechanical strength, the first problem in the design of a rational insulator is the determination of the dielectric thickness between the electrodes. The curve 1 in Fig. 6 gives the puncture voltage of one type of porcelain against thickness. This curve was obtained with the form of electrodes shown in the figure, and is the basis of the design herein discussed.

The development of the hardware to meet the requirements of symmetrical shape has been an interesting one. The first development in this design was approximately the insulator shape shown in Fig. 7, and the hardware was a solid cap at each end cemented into the porcelain. Electrically this was an excellent design, but on the application of the alternate immersion test wherein the units were immersed alternately in boiling and freezing water, it was soon found that the solid cap cemented into the porcelain was not permissible. The wide temperature variation imposed by this test damaged the porcelain rendering it mechanically and electrically unreliable. A gradual development towards flexibility resulted, after a great deal of experimental work, in the flexible spider shown in the design of Fig. 7. One of the features governing

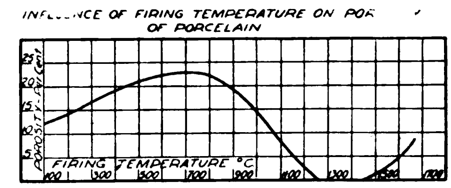

Fig. 8

the development of this spider was the requirement that the plane of dielectric stress be maintained as near as possible normal to the plane of mechanical stress a condition which this method of attachment fulfilled admirably. The legs of this spider are fastened into the porcelain by an alloy having sensibly the same coefficient of cubical expansion of porcelain. By this means the well-known detrimental effects of cement are eliminated. The flexibility of the spider legs combined with this alloy give a unit that will withstand the alternate immersion test an indefinite number of times without any detrimental effect on the insulator. Tests have been made of this character up to 100 alternate immersions followed by high-frequency flash-overs and final breaking in a tension machine. All of the tests indicate that the unit as designed is free from the detrimental effects of wide temperature variations. After the development of this spider, curve 2 of Fig. 6 was made to determine the efficiency of the spider as a flux distributor. This efficiency is given in curve 3 of the figure and shows in the thickness of the porcelain used in the unit (57 millimeters), $2\frac{1}{4}$ in., a value of 72 per cent. This value is the ratio of the puncture voltages in the same thickness with the two types of electrodes, but as the puncture volt-

age is that at which the dielectric flux concentration at its point of maximum intensity exceeds the critical value, it is also a measure of electrode efficiency as a means of obtaining a uniform flux distribution.

The difficulty of making a porcelain insulator of this thickness has deterred manufacturers from progress in this direction, and we can substantiate a manufacturer most emphatically in this difficulty. A great many thousand dollars were spent before we discovered how to manufacture porcelain in this thickness without firing strains or porosity. It may be said here that the solution involved a radical departure from the prehistoric methods of porcelain manufacture that have been followed continuously for a long time by most porcelain factories. These changes are met throughout the process from the original handling of raw materials through the final firing processes, and it is only upon the development of these special processes, utilization of special drying methods and the use of the tunnel kiln for firing control that the problem has finally been solved. Fig. 8 gives the firing temperature porosity curve for one porcelain body and illustrates the narrow range over which this body may be fired to produce non-porous porcelain. In securing this curve the porcelain test pieces were fired to various temperatures and cooled, the test being made at room temperature, that is, the abscissas on the curve represent maximum firing temperature of the sample while the ordinates are the porosity of the sample after firing and cooling. A discussion of this characteristic has been given.[1]

Tests And Investigation of The Rational Insulator as Developed

As mentioned before, the impulse ratio of a string of insulators is of very great importance and with an insulator of rational design the impulse ratio should be high. The curves in Fig. 5 are very interesting in this connection and show the excellent results secured by this rational design in impulse ratio in the individual unit and strings. The unit as designed will, therefore, for a given number of units in the string, have a very much higher flash-over to lightning disturbance than the conventional type unit with a lower impulse ratio. This, combined with the large mass of porcelain, thick petticoats and general substantial character, gives the unit a remarkable ability to withstand lightning conditions and their resultant power arcs.

The claim has been made that repeated mechanical stresses will weaken porcelain, and also that porcelain in tension is weakened electrically when under stress. In investigating this, units of the type described have been stressed to 9000 lb. (4100 kg.) in the tension machine and subjected to dry flash-over at 200,000 cycles while under stress. This test was continued until the units had been under stress for several days and at the application of high-frequency flash-over for as long periods as 100 hours there was no indication that this mechanical stressing affected in any way the dielectric quality of the insulator. This is not surprising as the plane of mechanical stress is normal to the plane of dielectric stress as before mentioned. To study the effect of repeated or continued mechanical stress, strings of insulators have been hung out in the weather with a dead load of 5000 lb. (2270 kg.) each, and periodic tests are being conducted to ascertain the condition of these insulators, and the results so far have not shown any indication that this fear is warranted. Further, repeated shocks and tension tests on porcelain samples under various conditions indicate that porcelain is not injured in any way by repeated stressing, unless the applied loads stress some part of the porcelain beyond its ultimate strength. If this is done, porcelain will fail quite naturally, as will cast iron or any other brittle material, but the results of practise and continued and careful laboratory tests indicate that the previous fear of fatigue due to continued working of the porcelain mechanically is ungrounded. These tests are being continued and some rather interesting reports will be made to the Society in the future as to the results secured from laboratory and practical tests of this nature.

Factory Tests

It is doubtful if any developed tests at the present time that can be applied to an insulator without injuring it will prophesy its operation when on the line as to depreciation and for that reason we have made a rather radical departure in some respects from ordinary factory testing.

The fuchsine method of testing for porosity[2] is used in our factory, one unglazed unit being placed in each car of 70 insulators that pass through the tunnel kiln. This unit is broken up immediately on the removal of the car from the kiln and the pieces subjected to the fuchsine test. On the slighest penetration the entire carload is rejected and scrapped. This test gives a very satisfactory control test for porosity and guards effectively against any errors in raw materials or reading of the pyrometers that might cause porosity through firing outside of the permissible range as indicated in Fig. 8. It insures the scrapping of the small number of porous units inevitable in quantity manufacture of porcelain. After the inspection of fired porcelain the hardware is assembled and each unit is subjected to a 5000-lb. (2270-kg.) mechanical load. After this load each unit receives a two-minute dry flash-over at 200, 000 cycles. The units are then again inspected and turned over to the assembly department. It is be-

lieved that the best insurance the customer can be given as to the quality of the product he is buying is that the manufacturer started with a rationally designed product correctly proportioned and manufactured to fulfill the required conditions. A certain percentage of the finished product should then be tested to destruction to determine that the required standards of manufacture are being maintained. To this end a

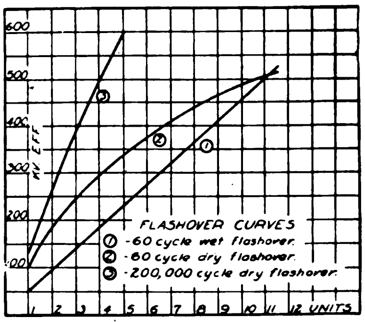

Fig. 9

certain percentage of the product delivered to the shipping department is selected at random by the research laboratory and tested to destruction. The plotting of the data secured from these tests establishes a probability curve for the product considered, the study of which has revealed some very interesting things regarding manufacturing limitations.

Furthermore, when this probability curve is once established with accuracy any test falling outside the determined limits on this curve is a danger signal and further tests are at once made. If these tests confirm the first results an immediate investigation is made to determine wherein the factory processes are not maintaining the required standards. It is believed that this method of testing is better than the imposition of very severe acceptance tests on all the units, as such tests, unless carried to destruction, tell very little regarding the future performance of the insulator.

Operating Characteristics and Selection of Units

The selection of proper insulator strings for any given transmission line involves a rather careful study of a good many conditions. Given a rationally designed insulator, the individual characteristics of which are accurately known, the selection of the number of units for a string for given conditions is a matter of the development of the proper safety factor for the right conditions, using as a basis the worst line conditions liable to arise. In this connection the curves of Fig. 9 are of considerable interest. Wet flash-over values are rather deceptive. Due to the leakage currents, the distribution of the voltage amongst the units of a string is very much improved. Furthermore, wet flash-over values are apt to be erratic unless conditions are very carefully controlled as to the purity of the water used, precipitation, size of spray, etc. In general, the selection of the proper strings involves a determination of the worst electrical conditions likely to be met on the line and the selection from characteristic curves of the insulator of a string that will give the desired safety factor under these worst conditions. The curve 3 of Fig. 9 is very interesting as a measure of protection afforded to disturbance of lightning frequency. In Fig. 10 some rather interesting data are given, that is too often ignored in the selection of insulators for a transmission line, especially when it is remembered that an increase of 45 deg. cent. (110 deg. fahr.) in temperature is equivalent to an elevation of 3000 ft. (914.4 m.) of the line. After a preliminary selection of a string has been made, a study should be made of the duty on the conductor end unit to determine whether or not from the characteristics of the insulator this unit is working within safe limits. If not, the string should be readjusted to operate this unit under proper conditions, and then the results examined on the basis of the margin of safety afforded on the failure of one unit. The readjusted values of the voltage on the different units and the resulting safety factors will give a very good idea of the advisability of further insurance against trouble by the addition of end units. This question is, of course, an economic one, and the amount of money that it is permissible to pay for such protection is a question that each engineer must decide for himself.

Future Progress

The insulator situation today is in a state of constant development and considerable progress may be expected in the near future. Certain recent investigations indicate[3] that piezo-electric effects may be of

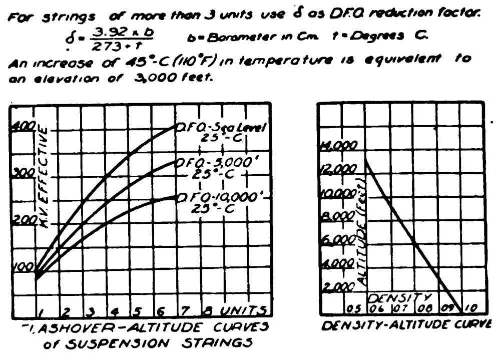

Fig. 10

considerable influence in porcelain depreciation and recent developments indicate that this situation will soon be met in a very satisfactory manner. Also some rather interesting work is being done at present on the solubility of porcelain in water under the conditions existing in the capillary passages connecting the voids of porous porcelain. Investigations are under way using pressures around 10,000 lb. per sq. in. with very

3. W. D. A. Peaslee, "High-Tension Insulator Porcelain," A. I. E. E. White Sulphur Springs, June 29, 1920.

high and very low temperatures to accelerate this action and, by means of the microscope, determine from samples of porous porcelain that have depreciated in the field compared with the porcelain subjected to accelerated tests in this manner, to what extent this solubility may be responsible for increasing porosity. The problem of very high-voltage transmission systems is being studied and some new types of insulators made up of rather special porcelain bodies are being developed that will meet this situation without difficulty and by the time there is money available to build any of the large projected extremely high-voltage lines, insulator manufacturers will be ready to meet the problem.

Carbon and Commutator Wear[1]

BY R. E. HELLMUND

Engineering Dept., Westinghouse Electric & Mfg. Co.

WITH most theories on commutation the sparking voltage between commutator segments or the average voltage across the brush is used as the principal criterion for the commutation. More recently the idea has been advanced that the problem of commutation is very much the same in d-c. and a-c. machines as long as in both types of machines the sparking voltage is properly taken into account. It has also been shown by extensive data collected under practical operation that certain sparking voltages will have very similar effect in both a-c. and d-c. machines if other conditions are kept alike.[2] This should not be construed, however, to mean that the sparking voltage is the only important factor which enters into the commutating problem, especially into the wear of the carbons and the commutator. In other words, while it is true that the sparking voltages are of the same brand no matter whether they are induced in an a-c. or d-c. machine, the same sparking voltage may give widely different results under different conditions in either type of machine. The fact that very often the comparative data obtained with the same sparking voltage give rather consistent results for the carbon wear with different types of machinery is simply due to the fact that a good many factors, as for instance, current density, temperatures, commutator speeds, etc., are similar in a great many practical machines regardless as to whether they are a-c., d-c., or whether they are for industrial or traction purposes. Nevertheless it seems to the writer that the importance of these various factors upon the commutating problem should not be overlooked and that a detailed knowledge of the various factors as affecting brush wear is of utmost importance. If it is considered how important the brush and commutator wear is in connection with all kinds of commutating machinery it seems surprising how little investigation has been made along this line. While there are quite a number of tests available giving brush friction and contact resistance, practically nothing is known as to how sparking voltages, current densities, peripheral speeds, etc., affect the brush and commutator wear. It might, therefore, be in place to give here a few tests along this line with which the writer happens to be familiar.

One test which the writer has in mind was made with rather soft graphite brushes on slip rings for the purpose of investigating the effect of sparking as often caused by mechanical vibration. The vibrations were obtained by connecting the carbons to a little mechanical device vibrated by means of an alternating current magnet. It was thus possible to produce arcs as they are at times experienced on slip rings under severe mechanical vibrations. It was found that while with very low densities in the carbon quite appreciable arcing was produced, no measurable carbon wear was found over an extended period of test. On the other hand, it was found that with very large current density but without arcing it was also impossible to measure any carbon wear. While again, when arcing was combined with an appreciable current density the carbon wear was quite rapid. This simply brings out the fact that with machines having some arcing on the brushes, the current density has an appreciable influence upon the practical results obtained. It was also interesting in connection with this test that the arcing with low densities, giving practically no wear, looked nearly as bad as the arcing with high current densities, which shows that visible commutation does not always give a measure of the wear of the carbons and the commutator.

Some other interesting facts were brought out by a series of very careful tests carried on at the writer's suggestion by Mr. H. H. Wentworth. In these tests an alternating-current railway motor was run with the brushes on the commutator but without any load current in the armature, while at the same time the fields were excited by alternating currents. In this manner it was possible to determine exactly the sparking voltages in the armature coils by simply measuring the field voltages. In so far as the test was intended for

1. This material was given in a discussion of the paper by Mr. G. B. Lamme on A-C. Commutator Motors, presented before the Schenectady Section of the A. I. E. E., April 2, 1920, see A. I. E. E. JOURNAL, March 1920. Since the writer has been repeatedly requested to publish the material given there, it has been written here in the form of a short article.)

2. B. G. Lamme loc. cit.

getting information on railway work, the excitation of the fields, and therefore the sparking voltage, was arranged to be on only half of the time in order to get the effect of coasting without sparking voltage. The field excitation was on for 30 seconds and off for 30 seconds. Furthermore, the motor was reversed in its direction of rotation every hour. Fig. 1 shows the carbon wear per 1000 miles of commutator travel as dependent upon the sparking voltage between segments. All tests were made with uniform carbon pressure and a commutator speed of about 3000 ft. per

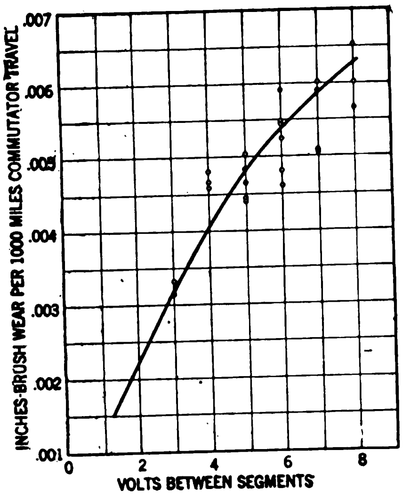

FIG. 1

min. Since the carbon covered about 1.8 segments the average voltage across the carbon is about 1.8 times the values given in the curve. It is at once surprising how small the carbon wear is as found from this test in spite of the high sparking voltages, which were as high as 8 volts between segments and 14.3 volts across the brush. This wear was only about one-fifth to one-tenth of what is obtained with the motor in actual operation with high current densities in the carbon but appreciably lower sparking voltages. This again bears out the fact that the current density has an appreciable influence on the current wear. It is, however, not altogether safe to conclude from these tests that the load current densities have directly as much influence as might be supposed from casual inspection of the tests. It was noticed on an inspection of the carbons on this test that they showed a very bright surface near both edges over small distances b and c, Fig. 2, while the center portion marked d showed plenty of evidence of arcing. This condition was obtained on account of the tilting of the carbon in the holder, although the clearance was kept down to a practical minimum the tilting was found to be unavoidable. The natural consequence is that the carbon instead of actually short-circuiting 14.3 volts covered only a distance c of the commutator and this short circuited a very much smaller average voltage. The relatively small short-circuit currents formed over the distance c, had plenty of time to be interrupted over the distance d, burning it slightly, but apparently never reached the portion b, as otherwise they would have taken off the polish from this part of the surface during the hour run in the same direction. In other words, the small carbon wear in the tests cited is largely due to the fact that the actual short-circuited voltage was not nearly as high as indicated by the curves. While running light, as in these tests, the wear of the portion c would be kept very small simply because the short-circuited currents and the local densities were small. It is probable, however, that as soon as the load current is sent through the brush the densities in the small portion c will be so excessive that the surface would quickly disintegrate and cause a rapid wear, thereby bringing at the same time a larger portion of the brush into contact with the commutator which indirectly increases the short-circuited volts and the short-circuited currents; thus the presence of the load current not only raises the density directly but indirectly raises the sparking voltages across the effective brush contact and consequently the densities caused by the short-circuited currents. In other words, we have a cumulative effect, causing the very much increased brush wear.

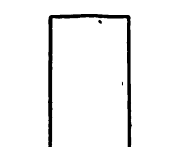

FIG. 2

Another interesting fact developed in connection with this test, namely, that the carbon wear without any sparking voltage was considerably higher than the wear with moderate sparking voltages. For this reason the curve in Fig. 1 is not carried to the zero point. This fact is first somewhat surprising but may be explained by the fact that the friction of carbons usually is lower with currents than without. It seems that the flow of any current affects the carbon so that the small graphite particles are loosened, and serve as lubricant, thus reducing the friction, and therefore, the carbon wear. It was further surprising to find that with the tests referred to, which were carried on with no sparking voltage for half the wear obtained with no sparking voltage at all. It was later found, however, that while the friction went down as soon as the sparking voltage was put on, it would take some time before the friction would increase after the sparking voltage was interrupted. This is undoubtedly due to the fact that the graphite particles caused by the flow of the short-circuited currents continue to adhere to the commutator for some time after the effect of the current had stopped. This brings out the interesting fact that while a short coasting period in railway motors may have a beneficial influence all around it may be found that a long coasting period is not very advantageous with respect to carbon wear. This, of course, does not mean that a long coast is not beneficial insofar as it cleans the commutator. On the contrary the higher friction during coasting, causing increased wear

for both carbons and commutator is often essential in giving successful operation. This is especially true with non-undercut commutators, but also to some extent with undercut commutators to which these tests apply.

Fig. 3 shows some further interesting curves obtained with the same motor. They show the dependency of the brush wear upon the commutator speed for various sparking voltages. It will be seen that the wear for low speeds is comparatively higher, that it subsequently decreases for higher speeds, but then increases again for still higher speeds. The high wear at low speeds is easily explained because with such low

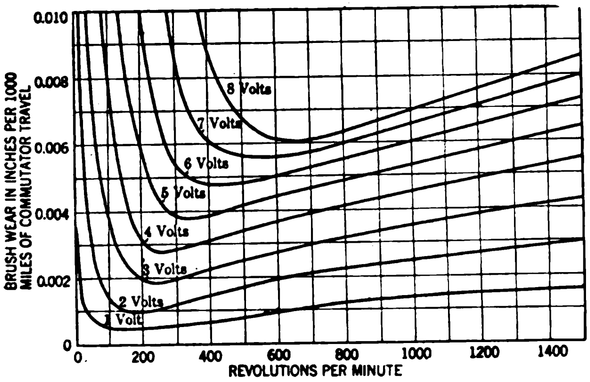

FIG. 3

speeds the carbons are in intimate contact with the commutator and each coil is short circuited long enough to permit the short-circuited currents to fully establish themselves, and furthermore, in opening the short circuits a long arc can be drawn out having plenty of time to bring about considerable burning effect. It is also natural with increasing speed that the inductive effect of each armature coil does not permit the short-circuited currents to build up to the full value and the time for the arc to burn off particles is materially reduced. It is somewhat more difficult, however, to explain why the wear again increases with the higher speeds. It may be that the vibrations set up with the higher speeds cause the carbon to jump up and down on the commutator thereby causing an arc under all portions of the carbon, thus causing greater wear. This supposition is somewhat supported by the fact that in the tests made there was an appreciable carbon breakage with the higher test speeds. It seemed that around 1400 rev. per min. a natural period was approached which caused sufficient vibration to bring about carbon breakage. This incidentally explains the carbon breakage experienced with some railway motors in operation in a good many cases where previously gear vibrations or other mechanical shocks experienced in railway work were supposed to be the cause of the carbon breakage.

An attempt was made to explain the higher carbon wear by higher losses in the contact surface. For this reason the short-circuit losses were determined and found as shown in Fig. 4. It is at once seen that the large wear at low speeds coincides well with high losses at the same speeds. On the other hand the loss curves show no increase for high speed corresponding to the rise of carbon wear for these speeds.

Possibly the higher carbon wear at the higher speeds might be explained by the theory that the lubricating graphite particles are thrown off the commutator by the centrifugal forces to a larger extent. This would, of course, result in increased friction and consequently in increased wear.

Another possible cause for the higher carbon wear at the higher speeds might be the fact that the high speed of interrupting the current causes sufficient self inductive voltage to maintain the arc longer, thus causing additional carbon wear. This leads to a point which has been given too little attention in all commutating theories. In machines having low sparking voltages and therefore no arcing at all, this point is, of course, of little importance, but in any case where appreciable short-circuited currents can form, the self induction of the armature coil will, of course, materially increase any sparking voltage at the moment the short-circuited current is quickly interrupted while one of the segments leaves the carbon. The fact that this self-inductive kick has an appreciable influence on the commutator wear was brought out very noticeably in some alternating-current motors under extreme operating conditions. It was found that certain commutator bars burned more than others. The reason for

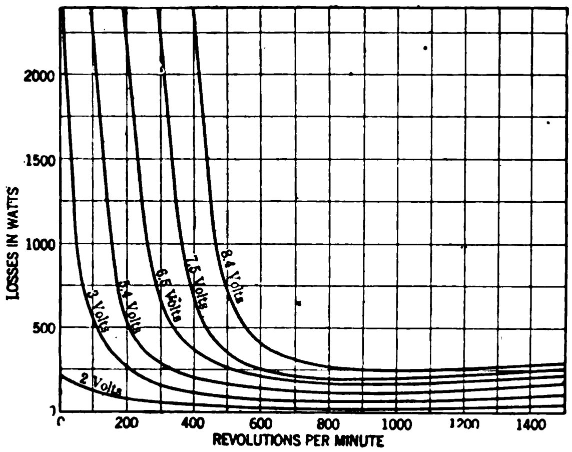

FIG. 4

this can be very readily explained in combination with Figs. 5 and 6. Let us assume, for instance, that the coil 1 is short-circuited and segment *a* is about to leave the carbon while at the same time coil 2 is being short-circuited on account of the segment *c* coming under the carbon. This means that the short-circuit current in coil 1 is decreasing while that in coil 2 is increasing, consequently the sum of the two-short circuited currents remains about the same and the flux surrounding the coils, as indicated by the dotted line does not need to change while the short-circuit currents

are transferred from coil 1 to coil 2. This in turn means that there will be no inductive kick when the segment 2 leaves the carbon, and therefore, there is no burning on segment *a*. The same holds true when the short circuit is transferred from coil 2 to 3 and from 3 to 4, meaning that there will be no burning on segments *b* or *c* either. The conditions change, however, materially when the short-circuited current of coil 4 is interrupted. In this case the flux around this slot disappears and a new flux forms around the next slot. Therefore, we will have an appreciable inductive kick when the segment *d* leaves the carbon, and this is the reason why this segment burns appreciably. A marked improvement was obtained in the case under consideration by adopting a coil with split throw, as shown in Fig. 7, with which only one coil side loses its flux at a time. Therefore, the inductive kick is cut to half its former value. In fact it can be shown that with such a winding and the motor rotating in both directions of rotation the burning is uniformly distributes over all the bars, thereby giving uniform wear of the commutator and avoiding the cumulative burning of the segements which will always be experienced when the wear is not uniform.

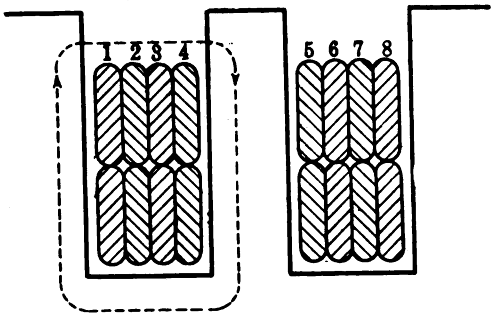

Fig. 5

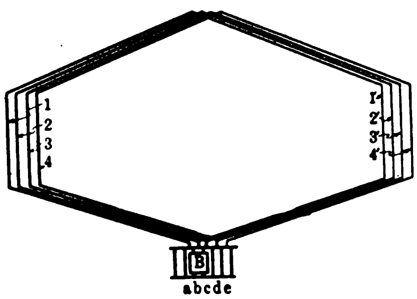

Fig. 6

While as previously brought out, a certain sparking voltage will have the same effect under otherwise equal conditions no matter whether it appears in an a-c. or d-c. machine, attention might here be called to one difference in conditions existing between a-c. and d-c. machines. In a d-c. machine the current density as well as the sparking voltage is more or less uniform for a given load current and both exist at the same time.

In other words, the short-circuit currents caused by the sparking voltage are uniformly superimposed upon the load current densities in the carbon. In a-c. machines this is not true with regard to all of the sparking voltages. While there is also one sparking voltage which is caused by the rotation of the conductors in the fields set up by the armature magnetic motive force which is in phase with the load currents, there are other sparking voltages in a-c. machines which are out of phase with the load current. The fluctuations of the main field in the single-phase series machine for instance, induces a sparking voltage which is 90 deg. out of phase with the load current. Therefore, the short-circuit currents set up by this voltage are out of phase with the load current. It is quite possible that with the two current densities being out of phase the commutator and carbon wear will be found different than that obtained when the load current density and the short-circuit current density are in phase with each other. In fact practical experience indicates that any sparking voltage being out of phase with the load current density causes smaller carbon wear than a sparking voltage which is in phase with the load current.

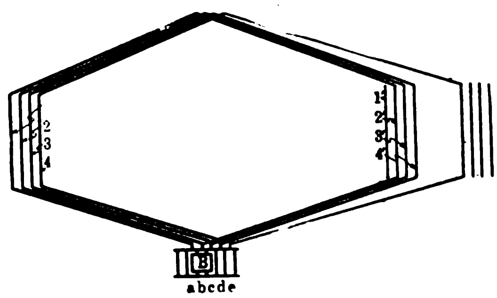

Fig. 7

The above tests and facts are merely cited in order to stimulate some interest in this problem as a whole and in order to indicate how the brush and commutator wear is appreciably influenced by various factors. The tests given here are too incomplete to allow any safe conclusions or to fully support some of the ideas advanced in the discussion. It would, therefore, seem very desirable that similar investigations determining the influence of current density, temperature, speed, etc., be carried on in the future, and it is believed that by acquiring, in this manner, full knowledge of the various phenomena it will be possible to extend considerably the practical working limits of all commutating machinery.

A Direct Recording Method of Measuring Magnetic Flux Distribution

BY F. S. DELLENBAUGH, JR.

Instructor & Research Assistant, Massachusetts Institute of Technology.

General Problem

IN undertaking an investigation in some of the more elusive refinements of dynamo-electric machinery design it became necessary to measure and analyze such a multitude of curves of flux distribution, that the labor and time required by existing methods practically prohibited the investigation. After some experimentation the method described was developed, which has the advantages of speed, accuracy and minimum effort in producing results.

This apparatus represents merely one detail of the means toward an end, and is rough in construction, being assembled from materials at hand, but the results are so satisfactory that it was thought advisable to describe the method in order that others might avail themselves of its simplicity.

Principle of Apparatus

The most common method of measuring flux distribution involves a search coil and ballistic galvanometer. Those who have worked with this method will readily appreciate the time involved in making a detailed survey of a magnetic field of any extent. Other methods such as the Grassot fluxmeter, change in resistance of bismuth wire, integrating volt-second meter etc. were investigated, but for one reason or another did not lend themselves aptly to the particular problem.

A revolving search coil fitted with a collecting device and operating at a high and constant speed was then thought of. The only objection seemed to be possibility of contact trouble at the brushes. The principles involved are the same as in any rotating generating machinery, the particular form of the parts being extreme. There appears to be no record of its having been previously tried, in spite of its simplicity of idea and somewhat obvious application.

In brief the apparatus consists of a search coil of very small diameter, and length approximately equal to the surface across which the flux distribution is to be examined, wound with a closed-coil winding and fitted with a commutator. The coil is rotated by a small storage battery motor, fitted with a governor to control the speed, and a magneto to indicate the speed. The voltage generated in the coil will then be proportional to the flux density of the field in which it rotates, other factors being constructed or maintained constant.

This voltage may then be read on an indicating meter or better, projected upon a photographic recording device by a reflecting instrument. The commutator was chosen rather than slip rings, first, because the component density in a definite plane may thus be determined, and second, because of the greater sensitivity and simpler technique obtained with direct-current instruments.

Details of Construction

Fig. 1 shows a drawing of the search coil. The "armature core" is constructed of bakelite to avoid eddy currents, 0.22 inches in diameter, about four in. long, and has four slots 0.05 inch wide by 0.07 inch deep. On each end a brass cup is attached, the small one on the left being merely a bearing to steady the coil, and the long extension on the right carrying the commutator and extension for attachment to the driving motor.

A four-part commutator is used, as a compromise between too greatly fluctuating voltage with two parts,

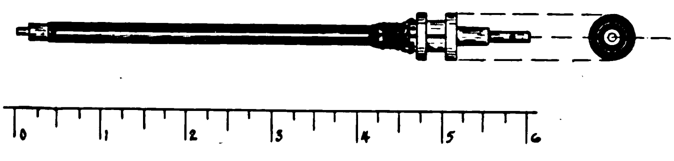

Fig. 1—Search Coil. Bakelite Core, Four Slots, Four Bar Commutator.

and two great construction difficulties with a greater number of parts. The bars are made of gold, mounted upon a hard rubber sleeve and held in place by hard rubber "shrink rings" reinforced with brass. The dimensions of the commutator are 0.25 in. diameter by 0.15 in. face.

The winding consists of five turns per coil of No. 38 d. s. c. copper wire, connected in the usual closed coil manner, with the bars placed so that a line drawn through the commutating points is in the same plane as the magnetic field generating the voltage, and the brushes therefore at right angles to the field, tangential type being used. This allows the coil to be approached close to the magnetic surface being explored. The brushes themselves consist of laminated strips of thin phosphor bronze tipped with silver, and are mounted so that they may be rotated around the commutator through 180 deg.

The coil is driven by a small motor, in this case a six-volt "Klaxon" horn motor being used. It is considerably larger than necessary but it was the smallest available. Fig. 2 shows the complete assembly of coil

motor, and governor. The magneto was not attached at the time the photograph was made. The second rod projecting from the bottom of the motor is a steady-rest for the end of the coil, as otherwise it will not run

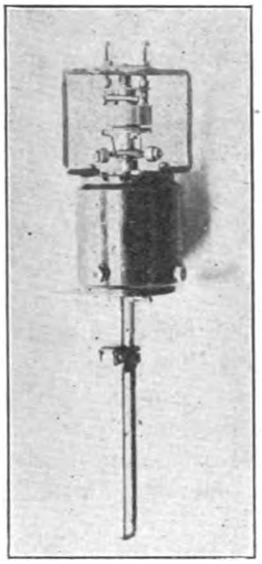

FIG. 2—SEARCH COIL AND DRIVING MOTOR SHOWING COIL AND STEADY REST, WITH GOVERNOR ON TOP OF MOTOR

entirely true due to slight unbalance and slight warp in the bakelite.

SPEED CONTROL

As the speed control is very important, Fig. 3 shows a drawing of the governor, which is a combined centri-

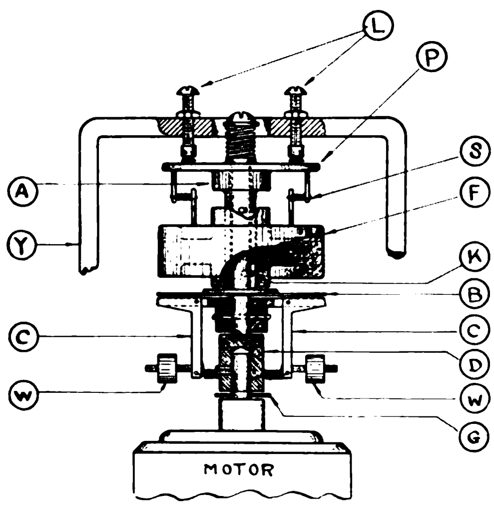

FIG. 3—GOVERNOR. COMBINED INERTIA-CENTRIFUGAL TYPE FOR CONTROLLING SPEED

fugal and inertia type. The collar *D* carries a shaft which runs up through the whole device. It also has fixed to it a plate which carries the three centrifugal weights *W* at the ends of the bell-crank arms *C*. These weights are threaded upon their carrying pins in order to balance for running speed. When these weights fly out they push up on the plate *B* which lifts both the flywheel *F* and the friction plate *P*, and forces the latter against the leather friction rubbers *L*. So far it is similar in action to the well-known phonograph governor. It was found, however, that this type alone allowed small instantaneous fluctations or jumps in speed, which would occur before the centrifugal weights

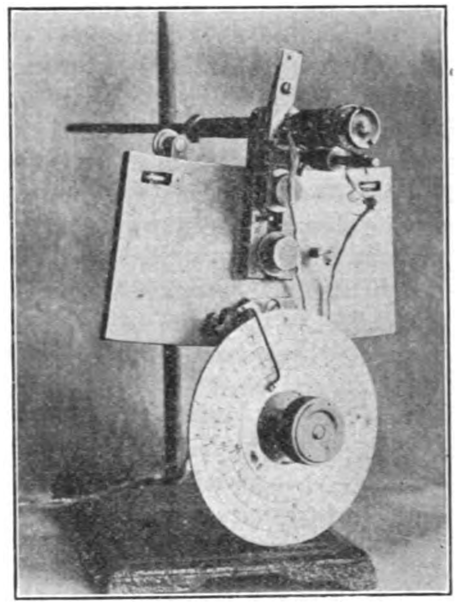

FIG. 4—CARRIAGE FOR SEARCH COIL. IN THIS CASE WITH TYPE OF COIL USED WITH BALLISTIC GALVANOMETER. MOTOR DRIVEN COIL REPLACES PART MOUNTED ON SLOTTED BRACKET

had time to act, and introduced breaks and inequalities in the recorded results. Therefore the flywheel *F* was added. This runs loose upon the sleeve *K*, which sleeve carries the friction plate, and is keyed to the shaft so that it can rise and fall, but must turn with the

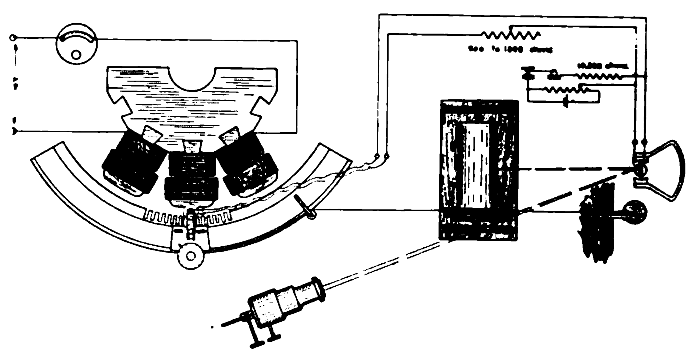

FIG. 5—GENERAL ARRANGEMENT OF TEST APPARATUS. SHOWING TEST COIL CARRIAGE, SECTION OF ALTERNATOR PUNCHINGS BEING EXAMINED, REVOLVING DRUM, REFLECTING METER, AND ARC LIGHT

motor. Therefore the flywheel running loose upon this sleeve will tend to run ahead or behind as the motor is retarded or accelerated. The upper end of the flywheel has two sloping notches in which rest pins attached to the friction plate sleeve. Thus rotation of the flywheel with respect to the sleeve tends to raise the friction plate when in one direction, and allows it to fall when in the other direction. Thus very small fluctuations in speed are immediately corrected by the

flwheel shifting its position with respect to the sleeve and increasing or decreasing the pressure upon the friction rubbers independently of the centrifugal weights. Very light springs S locate the normal position of the flywheel so that the pressure upon the friction plate is always carried through the pins and sloping notches.

Speed. Measurement

A small magneto, not shown, is attached to the top of the whole assembly and is calibrated to read speed

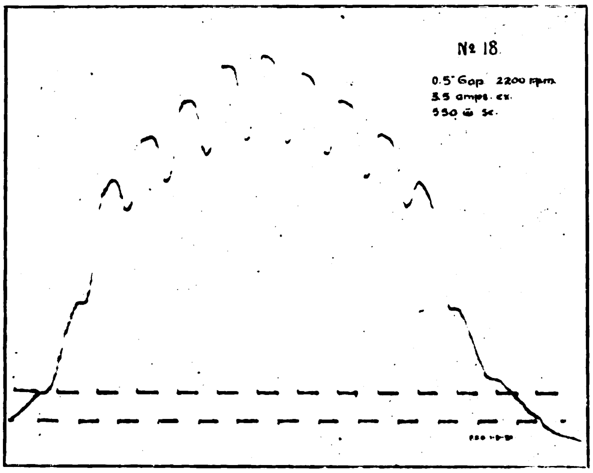

Fig. 6—Flux Distribution in Air Gap. 0.5-in. Air-Gap, Coil Moved Along Core Face. Position of Teeth Shown at Bottom

with an indicating millivoltmeter. This consists of a shuttle type armature 0.35-in. diameter wound with 200 turns No. 40 d. s. c. wire connected to a two-part commutator, and excited by a permanent magnet from a small voltmeter, the magnet being circular and about 2.5 in. in diameter. The voltage generated is about 100 millivolts at 2000 rev. per min. and as the peripheral speed of the commutator is only 80 feet per minute, no trouble with commutation has been found.

Recording Device

Some difficulty was experienced in obtaining a reflecting instrument that would follow quickly and truly the variation in voltage generated in the search coil. Galvanometers were too sluggish when critically damped, and would overshoot when not damped. The ordinary standard millivoltmeter has too low resistance and required enough current to cause commutating troubles, as well as large errors due to drop in coil. Vibration galvanometers or oscillograph elements either required too much current, or would pick up the frequency of commutation and vibrate continuously. Therefore a Weston ammeter was rewound with No. 40 d. s. c. wire, enough being wound on the moving coil to give 144.6 ohms resistance. The needle was bent back over the suspension, and a mirror fastened upon it centrally over bearings. This was found to give excellent results. It is very nearly critically damped and follows any change in voltage with great rapidity. Its sensitivity is quite high, giving a deflection of one cm. at one meter with 2.14 millivolts across its terminals, or 0.0148 milliamperes through the coil. This is about ten times the sensitivity of the standard millivoltmeter.

Arrangements of Apparatus

For the immediate problem in hand a section of a 12-pole alternator is set up horizontally on a table, the field coils excited, and the core being bare. A carriage running on a wooden track concentric with the core face carries the search coil assembly. Fig. 5 shows the arrangement schematically. A curved rack on the wooden track meshes with a gear on the carriage, and the gear carries a micrometer head graduated so that the position of the coil can be read to 0.05 tooth pitch. The search coil is mounted upon a slotted bracket so that it can be moved through any given plane in the air gap. Fig. 4 shows the carriage with an old type of search coil in place, which was rotated by a spring through 180 deg. when released by a trigger to obtain readings with a ballistic galvanometer. This is replaced directly by the present device, the remainder of the carriage remaining the same.

The reflecting meter is mounted upon the extreme right, and light from a small arc lamp, shown in lower center, is reflected upon a large drum. A small wire connects the drum pulley to the search coil carriage, and thus rotation of the drum is a function of the search coil position. The wire is arranged by means of pulleys so that it follows the arc of the wooden track, and after going once around the drum pulley, is attached to a counterweight.

The reflecting meter is connected to the search coil and also to a second circuit in parallel operated by a key. This is used to locate definite points on the curve by giving a small deflection when the contact is closed.

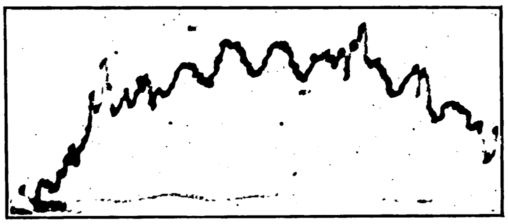

Fig. 7—Curve Obtained Without Governor and Commutator Improvements. Same Conditions as Fig. 6

Results Obtained

Fig. 6 shows the curve of flux distribution in the air gap along the armature core face. The positions of the teeth are shown at the bottom, being put in by means of the hand-operated key after the other curve had been made. The lines representing the bottoms of the slots are also the zero line of the curve. The depth of the slots is not to scale, but the width of the teeth and slots is accurate to 0.05 tooth pitch. The small wiggles in the curve at some places appear to be due to irregularities in the surface of the wooden track, as they are duplicated in the same spot with all curves.

Fig. 7 shows one of the first curves made before the motor was governed, and when there was also some

vibration in the brushes. It is included here for contrast and to indicate how successfully it is possible to eliminate the various sources of error.

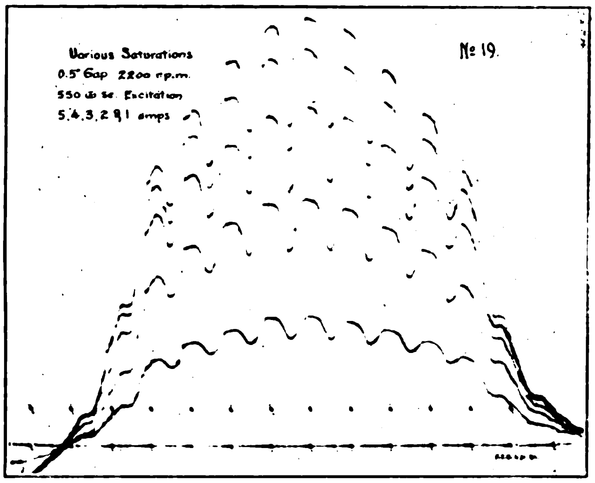

Fig. 8—Flux Distribution for Various Saturations. Points Above Zero Line Indicate Centers of Teeth

Fig. 8 shows a series of curves made at various saturations with the search coil close to armature core face. The saturation did not reach a high enough value to obtain noticeable change in the "tooth tufting". The maximum value of density was in the neighborhood of

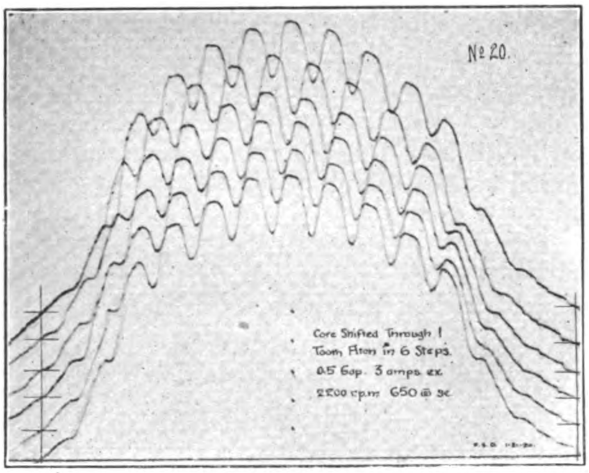

Fig. 9—Flux Distribution for Various Relations of Teeth to Pole. Core Moved a Little Around Pole for Each Curve. Total Movement from First to Last Curve One Tooth Pitch. Zero Line of Each Curve Displaced from Preceding One to Avoid Confusion

8000 gausses in the air gap. The zero line was put in by a second rotation of the drum with the search coil disconnected, and the dots above it represent the centers of the teeth, put in by means of the second circuit and key.

Fig. 9 shows the distribution of flux for the same saturation, but with the core shifted slightly with respect to the pole for each curve. The total shift between the top and bottom curves was just one tooth pitch, but the intermediate positions were not even fractions of the tooth pitch, although it was attempted to get them close to 1/6 pitch each, in order to obtain a smooth series. The zero point of each curve was displaced in order to avoid over-lapping and too much confusion.

The air gap in all the above curves was normal, 0.5 inch. In Fig. 10 the gap was increased to 1⅛ inches in order to exaggerate the results. Curves were then made for various positions of search coil from close to core face to close to pole face. The zero lines were displaced as before to avoid overlapping. The unbalance noticeable in the curve along pole face is due to the fact that only three poles are present, the distribution being investigated under the middle one, and slight differences in reluctance of either side pole unbalances the flux.

These curves are all made directly on photographic paper, size eight by ten inches, and have a base of

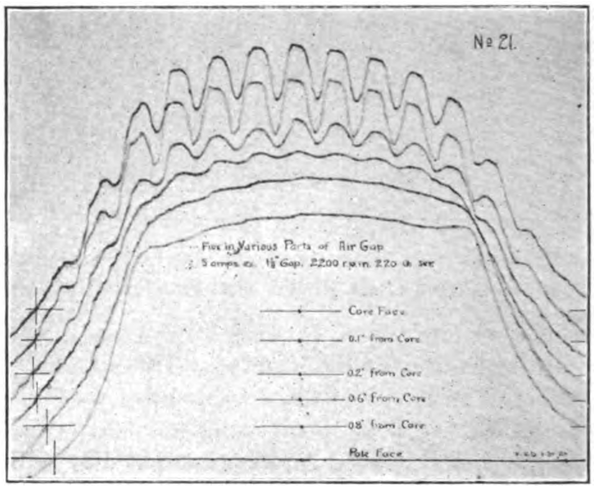

Fig. 10—Flux Distribution at Various Points in Air Gap Between Core Face and Pole Face. Air Gap Increased to 1 1/8 in. Zero Line of Each Curve Displaced from Preceding One to Avoid Confusion

about nine inches by maximum ordinate of about seven inches. This is convenient size, both for further treatment, and because they will file easily in standard letter file. The convenience of using paper instead of films eliminates a good deal of bother owing to a dark-room being unnecessary. All curves shown were made in an ordinary room in day time with the shades pulled down and black muslin hung up where the light was too intense. An old carbon incandescent lamp was used for local illumination to determine the setting etc. and is perfectly safe with most "gaslight" papers. The search coil is moved through the gap at a speed of about two feet per minute, and so gives ample time for exposure. It can be operated at about twice this speed without distorting the curves, and can be operated slower if longer exposure is necessary. Any "gaslight" paper may be used, these particular curves being made on AZO Hard-X developed in letol-Hydroquinone developer deficient in sodium carbonate, and well loaded with potassium bromide and potassium iodide

to give as much contrast as possible and cut down the small amount of fog present.

Accuracy

Enough work has not as yet been done with this apparatus to determine definitely the accuracy to be expected, but it seems to be quite high. The speed control holds to within 0.1 per cent for short periods, and within 1 to 2 per cent for periods of an hour or so. The speed can be read by the magneto to within 0.5 per cent easily, and the larger variation corrected before making a curve.

The contact resistance at the brushes of the search coil varies somewhat, but is very small percentage of the total resistance in circuit. The resistance of the search coil and brushes measured under conditions of speed varying from standstill to 3600 rev. per min. and current varying from normal to several hundred times normal, gave extremes of 1.23 ohms and 1.57 ohms. In actual use from 500 to 1000 ohms is used in series with the coil and reflecting meter, and 144.6 ohms in the meter circuit, makes a total minimum of about 646 ohms. The total variation in resistance of the coil is only 0.34 or 0.0525 per cent and so entirely negligible.

Under normal conditions the distance of drum to mirror is 24 in. and maximum ordinate 7 in., which requires a current in the meter coil of 0.434 milliampere. This gives an error of only 0.46 per cent if we neglect the resistance of coil and leads entirely. Its distortional effect upon the field being measured appears to be entirely negligible.

The accuracy of converting coil voltage to flux density depends upon the accuracy with which we can determine the area of the cross-section of the windings on the coil. By the ordinary theory of generating machines we find that the flux density is determined by the formula:

$$B = \frac{E \times 60 \times 10^8}{2.548 \times \pi \times \text{rev. per min.} \times n \times A}$$ for four-coil winding

where: B = Flux density in which coil operates.
E = Voltage coil generates.
n = Turns per coil in winding of search coil = 5.
A = Area of one coil of winding on search coil.

Thus the value of A is the only one indeterminate. In the present case this is about 0.06 square inch. It has also been found that the best operating speed is from 1800 to 2500 rev. per min. Below these limits uncontrolled friction is too great a part of motor load and the speed varies, and for higher values it does not run sufficiently well in balance to avoid vibration and difficulty with commutation. All the curves shown were made at a speed of 2200 rev. per min. It will be seen that the generated voltage has a magnitude of from 200 to 500 millivolts for normal air gap densities. Probably the most accurate way of determining the relation between voltage and flux density would be by calibration against a definite smooth magnetic field set up by a special magnet, and measured by ballistic galvanometer methods. This is a little roundabout, but by many trials and different conditions should lead to an accuracy of 1 per cent.

Therefore in general we should expect a combined accuracy of well within 2 per cent, and possibly within 1 per cent. It is believed that this compares favorably with other methods of obtaining similar results.

Speed of Obtaining Results

The time necessary to obtain one curve such as Fig. 6 by means of a ballistic galvanometer and point by point plotting method was at least an hour and a half and usually two hours. The time to make Fig. 6 was five minutes including all adjustments and developments.

Fig. 8 took ten minutes, for although having five curves, the majority of the time is required for setting up the various parts and making preliminary adjustments.

Fig. 9 took twenty minutes, since the adjustments between curves were more laborious.

A total of 31 curves was made easily in three hours, which works out at about six minutes per curve for an average, including adjustments of all kinds, and the usual details connected with any tests of this sort.

In an investigation such as the one under consideration where at least a thousand of such curves must be made, the time for making them by ballistic galvanometer method would be something of the order of two years, on the part time basis covering this investigation and is reduced to approximately five weeks by the above described device.

Further Developments

It is probable that a silver commutator and silver brushes similar to those used on d-c. integrating wattmeters would give more satisfactory results than the combination of gold and silver. The latter needs occasional lubrication with a trace of graphite. The motor could be reduced considerably in size and probably some form of synchronism motor would eliminate speed troubles. It is hoped shortly to reconstruct the device, so that the search coil will be still smaller in diameter, fully enclosed, so that it may be moved by hand against surfaces investigated and not require a track and carriage, and the driving mechanism all enclosed in a handle. In this form the whole thing will be light and portable. A small governed motor-generator set will probably provide a desirable form of power, machines the size of 8-in. fan motors probably being large enough, and operated from a six-volt storage battery. The recording device can be made much less bulky and arranged to fold like a camera, so that it becomes easily protable. A tungsten lamp would probably give enough light for drawing the curves, and the apparatus can be loaded in a dark corner or under a blanket and does not require a dark-room and safe lights. When these improvements have been made it will be possible to carry it to a machine anywhere and investigate flux distribution in detail with convenience and dispatch.

A Note on the Design of Insulating Bushings

BY F. M. DENTON

Northampton Polytechnic Institute, Clerkenwell, London.

THE break-down of an insulator usually sets in at the spot where the density of the electrostatic flux due to the conductor it is intended to insulate, is a maximum; for, as is well-known, this density is a measure of the volts per centimeter acting at that point upon the insulating medium. Observation of the discharges from an electrostatic machine shows that the atmosphere around a highly charged conductor breaks down most readily at points and sharp corners, while both theory and experiment show the advantage, if corona is to be avoided, of using, for a high-voltage transmission line, conductors of large diameter.

When, therefore, an insulating bushing has to be designed, for bringing the leads of a transformer or of an oil switch or lighting arrester through the metal case containing the apparatus, it is common practise to pass the actual conductor—a wire of small diameter—through a brass tube one or more inches in diameter forming the core of the insulating bushing. The electrostatic flux density at the surface of this tube—to which the high-voltage conductor is electrically connected—will be less than the density which would exist at the surface of the thin conductor if this were passed unsheathed through the bushing.

So far as the writer is aware it is customary to use as sheath a metal tube of as large a diameter, $2\,r$, as space will conveniently permit, and then, assuming a figure for the volts per centimeter $(d\,v/d\,r)$ to which the insulating substance may safely be subjected, to find the minimum allowable value for the external diameter $2\,R$ of the bushing from the equation.

$$\left(\frac{d\,v}{d\,r}\right) = \frac{V}{\{r \log_e (R/r)\}} \qquad (1)$$

in which V is the maximum instantaneous value of the test voltage that will be applied to the apparatus. This equation, though applicable, strictly, only to long co-axial cylinders, is found to give satisfactory results for transformer bushings and the like provided the edges of the metal sleeve through which the bushing passes are well rounded off.

The object of this note is to point out that the method of design which starts from an arbitrarily assumed value either of r or R is apt to lead to a larger and more costly bushing than the working conditions actually call for, and to show how, by the application of two simple rules, the most economical design can readily be worked out.

In conclusion a few published designs will be analyzed and compared with the most economical designs to which the rules given would have led.

It must, of course, be understood that, strictly, the rules are applicable, in their simple form, only to bushings built up of homogeneous material, and that they have no bearing at all upon condenser-type bushings.

1. *To Find the best Value of r for a Given Value of R.* The idea that when the external diameter $2\,R$ of the bushing is fixed the best design will be the one in which r is greatest, is misleading. There is, for each given value of R a best value of r, and whether the sheath diameter be made less or greater than the value thus indicated, the stress in the insulation will be increased. This best value of r is given by, $r = R/2.72$, an equation obtained by writing down the condition that $(d\,v/d\,r)$ shall be a minimum. The equation (1) given above shows that $(d\,v/d\,r)$ will be a minimum when

$$\{r \log_e (R/r)\}$$

is a maximum, that is to say, for that value of r which makes $d\,\{r \log_e (R/r)\}\,/\,d\,r = 0$

The solution of this equation is the formula just given,

$$r = R/2.72 \qquad (2)$$

It tells the best value for r when R is given, but it must not be supposed that when r is given this formula tells the best value for R—since, clearly, in this case the value for R which ensures the minimum stress in the insulation is the greatest allowable value.

2. *To Find the Minimum Allowable Value of R when V and (d v/d r) are Given.* This is the form in which the problem usually is presented to the designer.

In equation (1) we now set $(R/r) = 2.72$ and get,

$$\left(\frac{d\,v}{d\,r}\right) = \frac{V}{r \log_e 2.72},$$

and since $\log_e 2.72 = 1$ (because, strictly, the 2.72 should be 2.71828 . . . or "e", the base of the Napierian logarithms) this becomes $(d\,v/d\,r) = (V/r)$, or, calling $d\,v/d\,r$, the voltage gradient at the surface of the sheath, g, the rule becomes

$$r = V/g = R/2.72$$

or

$$R = 2.72\,(V/g)$$

and

$$r = R/2.72 = V/g,$$

For g the designer puts what he considers a safe working value of volts per centimeter for the material of the bushing.

The following is an analysis of published data of bushings; they are not selected but have been taken at random from reputable sources, and in each case it appears that considerable saving in the thickness of the bushing might have been made by decreasing R and increasing r without subjecting the insulation to any greater strain than that which must occur in the bushing actually used.

Material of bushing	Test voltage, volts	As used		Best values	
		R cm.	r cm.	R cm.	r cm.
Oil-filled	177,000	9.5	2.9	9.4	3.45

Reactors for Electric Furnace Circuits

BY HARRY A. WINNE

Power & Mining Engineering Dept., General Electric Co., Schenectady, N. Y.

IN any alternating-current circuit supplying power to an electric arc furnace, the reactance of the circuit is depended upon to stabilize the arc, and to limit the maximum current which will flow through the circuit in case the arc becomes short-circuited, due to the electrodes coming into direct contact with each other or with the furnace charge. The resistance of the buses, electrodes and charge will help to limit the maximum current, but its effect is small in comparison with that of the reactance.

It is the purpose of this paper to discuss briefly the various methods of introducing reactance into furnace circuits, but not to attempt to determine what the amount of this reactance should be. This value will vary widely in different installations, and depends upon the limit which must be placed on the maximum current surges in the circuit, always taking into consideration the fact that as the reactance is increased the power factor of the load will decrease.

As a matter of interest is included the curve in Fig. 1 illustrating graphically the relation between reactance and power factor in a circuit. As abscissas are plotted reactance voltages in percentage of the supply voltage, while the ordinates represent the power factor of the circuit in per cent. It might be noted that maximum current can be limited to twice normal value, by using 50 per cent reactance, with a normal load power factor of 86.6 per cent, which is higher than the overall power factor of the load drawn by the average induction motor-driven manufacturing plant. A power factor as high as 95 per cent at normal load can be obtained with an amount of reactance which will limit the maximum current to only slightly more than three times normal.

Incidentally, the ordinates of this curve also indicate the voltage drop due to resistance in the circuit, or, neglecting the resistance in the transformer and furnace leads, the actual voltage which is obtained across the furnace electrodes in per cent of the supply voltage.

In the following discussion the electrical circuit of the installation, or briefly the furnace circuit, is considered as beginning at the circuit breaker which connects the furnace transformer to the power supply line. The total reactance of this circuit is made up of several components namely the reactance of the transformer, of reactance coils if such are used, of the heavy current leads from the transformer to the furnace, including the electrodes, and of the charge itself.

The reactance of the transformer can be varied within limits, as can that of the leads and buses by changing the spacing between and the arrangement of the conductors, but practically there is a minimum value for any given installation below which the reactance cannot be diminished.

This minimum limit increases with increasing current-carrying capacity of the installation, and may actually become a serious handicap on very large furnaces.

However, there are numerous cases in which it is desirable to have a reactance even higher than what may be termed the "normal" value for the circuit. Such conditions may arise with furnaces of small capacity, on steel or other metal melting furnaces in which a high voltage is used for melting and a lower for refining, or when it is necessary to limit the maximum current surges to a very low value. In such instances it becomes necessary to adopt some means for inserting reactance into the circuit.

The means available for this purpose are: to make the transformer of high reactance; to so arrange the heavy current conductors as to obtain the desired effect; or to use external reactance coils on either the high-voltage or low-voltage side of the transformer.

High-Reactance Transformers

The ordinary power transformer has an inherent reactance of from 2 per cent to 6 per cent. This value can usually be increased to a maximum of about 20 per cent without excessively increasing the cost or decreasing the efficiency of the transformer. Consequently, if a reactance of not over 14 per cent to 18 per cent in addition to the normal value is desired *permanently* in the circuit, the transformer manufacturer can usually incorporate it in the transformer.

This method of obtaining additional reactance is only satisfactory if the high reactance is desired under all conditions of furnace operation, and should not be used when it is advantageous to vary the reactance during the operating cycle. Neither is it ordinarily satisfactory on melting furnace installations using different voltages during different portions of the operating cycle, as with the usual system of tapping the transformer high-voltage winding to obtain variable low voltages, the percentage reactance of the transformer is higher for the low-voltage connection than for the high. That is, a transformer designed to give voltages of 120 and 80, and have a reactance of say 10 per cent on the 120-volt connection, might have a reactance of 15 per cent on the 80-volt connection. The effect of this circumstance is decidedly disadvantageous, as the percentage reactance of the buses and cables is greater at the lower voltage,—assuming the same current,—than at the higher voltage, whereas a lower total reactance at the lower voltage would be advantageous.

*Presented at the Boston Meeting of the A. I. E. E., April 9, 1920

Additional Reactance Obtained by Arrangement of Conductors

Another method of obtaining additional reactance, when the same is desired in the circuit continuously, is to arrange the heavy current leads from the transformer to the furnace with a comparatively wide space between those of different phases.

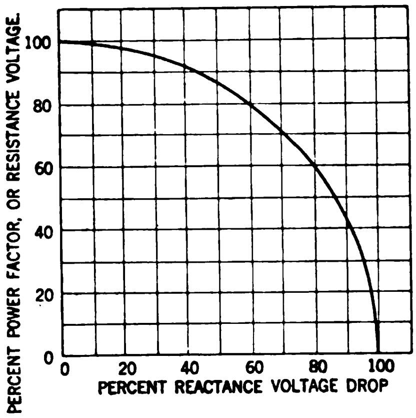

Fig. 1—Relation Between Reactance and Power Factor of a Circuit at Normal Kv-a. Load

Where the current per phase is high and the frequency 60 cycles, a considerable amount of reactance can be obtained in this way. As a matter of fact on furnaces of large capacity it is usually necessary to place the leads very close together, and sometimes interlace them, in order to prevent too high a reactance in the circuit.

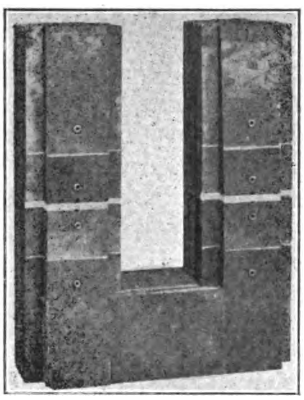

Fig. 2—Core of Iron-Core Reactor
Light Shaded Sections Represent Air Gap

As a consequence it is usually only on smaller furnaces, or furnaces using a high voltage during a portion of their cycle, that special provision for obtaining high reactance is necessary.

External-Reactance Coils

In many electric furnaces melting and refining steel and other metals a higher voltage is used during the melting than during the refining period. Owing to the higher voltage, and to the fact that conditions in the furnace during the melting portion of the cycle are such as to cause frequent current surges, reactance coils are often inserted in the circuit while the higher voltage is being used. These coils may be of either the iron-core or air-core type, and may be connected either in the high-tension supply circuit to the transformer, or between the transformer and the furnace.

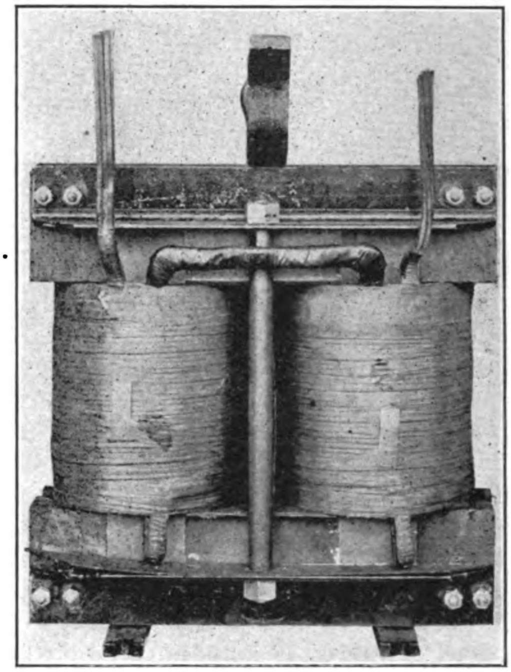

Fig. 3—Iron-Core Reactor Ready for Assembly in Tank

Iron-Core Reactors

The iron-core reactor consists simply of a number of turns of insulated conductor, wound upon a laminated iron core of magnetic structure very similar to a transformer core, except that it usually does not form an ab-

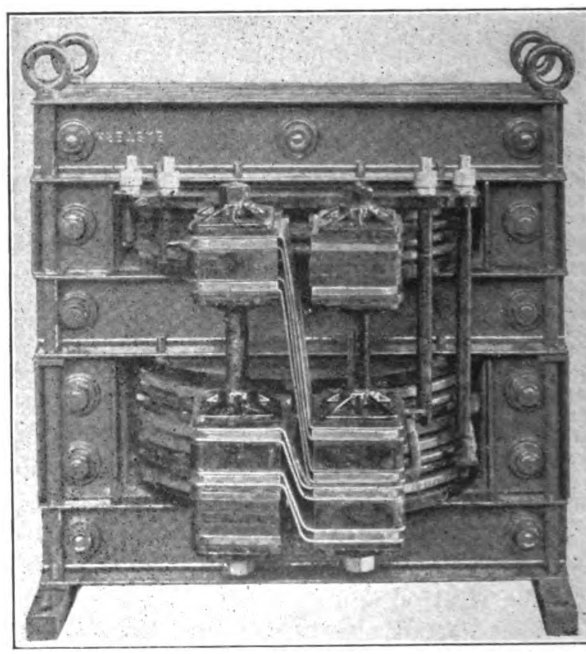

Fig. 4—Special Iron-Core Reactor with Auxiliary Short-Circuiting Winding

solutely closed magnetic circuit, but has a considerable air gap. The air gap improves the operating characteristics of the reactor, helping to reduce the magnetic saturation of the core through the current range for which the reactor is designed. This type of reactor may be air or oil insulated, and is usually self-cooled.

In the design of iron-core reactors which are depended upon to limit the current in a circuit, care must be exercised to insure that the iron core will not be over saturated at the maximum value of current which can

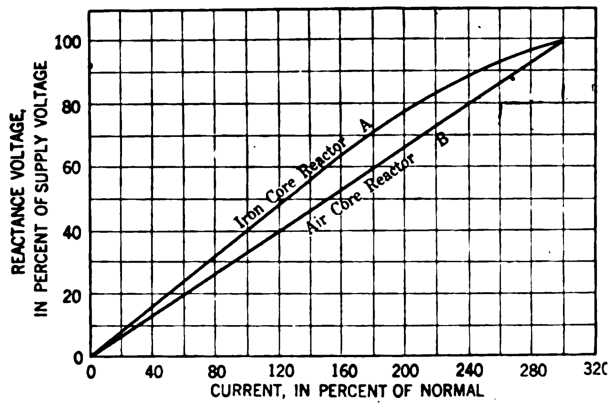

Fig. 5—Characteristic Curves of Iron- and Air-Core Reactors

be forced through the circuit. Otherwise, the effective reactance of the coil will decrease greatly just when its full effect is most needed. A characteristic curve for an iron-core reactor is shown in Fig. 5 curve A. While this coil has a reactance voltage of 40.5 per cent at normal current, it gives only 100 per cent reactance voltage at 300 per cent normal current. That is, while the current has increased to three times normal, the reactance voltage has increased to only 2.47 times normal. Obviously, for current-limiting purposes the iron-core reactor should be designed so that its entire working range will fall below the "knee" of the curve.

The effect of the hysteresis in the iron core is to cause a distortion of the wave of the reactance voltage which is practically equivalent to a time-lag, thereby reducing the effectiveness of the reactor in maintaining the arc as the supply voltage approaches the zero value of its cycle.

The iron-core reactor is chiefly used in circuits carrying currents of less than about 50 amperes, when a reactance of more than 4 or 5 per cent is required. Under such conditions an air-core reactor would require a very large number of turns to give the desired reactance, and the iron-core design is considerably more economical.

A rather unusual iron-core reactor is illustrated in Fig. 4. This particular coil was designed for an installation in which two separate arcs were to be supplied from two separate low-voltage coils on a single transformer. Consequently it was necessary to place the reactor in the low-voltage circuit, the normal current in which was 4000 amperes. Furthermore, it was desired to be able to cut the reactor in and out of the circuit by push button control. As electrically operated circuit breakers of the current capacity required were quite expensive, an auxiliary coil of a large number of turns was wound on the reactor core. Short-circuiting this auxiliary coil had the same effect in the main circuit as short-circuiting the reactor; owing to the turn ratio, the current flowing in the auxiliary coil, when short-circuited, was less than 200 amperes, and an inexpensive contactor could be used.

Air-Core Reactors

Air-core reactors, as the name implies, are coils with no iron or other magnetic material in their flux paths. Two typical methods of instruction of air-core reactors are illustrated. Fig. 6 shows what is termed the "disk-coil" type. This construction is used when a large number of turns are required to give the desired reactance, as in a low-current high-voltage circuit. A number of flat disk-coils of insulated conductors are assembled in a vertical stack and clamped between alloy spiders by means of insulators. The coils are spaced from each other by porcelain insulators, which support them at an angle of about 30 degrees to the horizontal, thus allowing good ventilation and cooling.

A "cast-in-concrete" reactor is illustrated in Fig. 7. In this reactor the conductor, of bare copper cable either solid or stranded, is solidly imbedded in specially

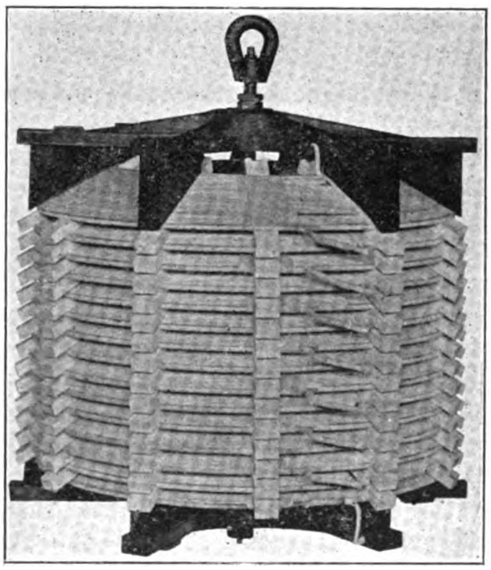

Fig. 6—Air-Core Reactor, Disk-Coil Type, Before Impregnation of Coils

treated concrete supports. The concrete is actually cast in place about the conductor, and is then cured in high-pressure steam, a process which secures a mechanical and electrical strength obtainable in no other way. The conductor and concrete are in very intimate mechanical contact, forming a strong rigid unit.

The vertical supporting members are mounted on a reinforced concrete base, which is in turn supported on

porcelain posts when the circuit voltage is above 1000.

The layers of conductors lie at an angle to the horizontal, alternate layers being dished in opposite directions, so that the space between conductors in adjacent layers increases with the number of included turns, and consequently the voltage, between the conductors.

There is no organic material whatever used in the construction of the cast-in-concrete reactor, consequently it is fire-proof and practically indestructible, except by actual melting of the conductor.

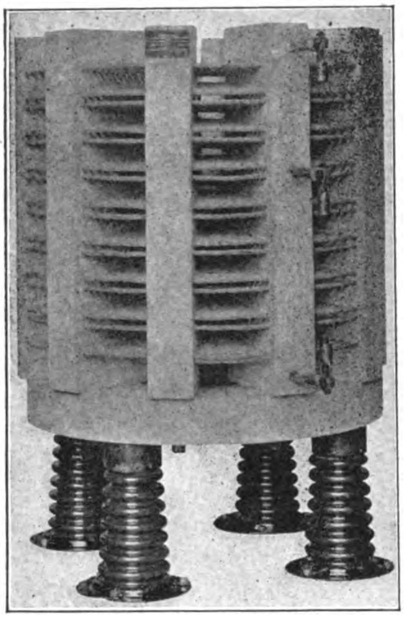

Fig. 7—Air-Core Reactor, Cast-in Concrete Type

The method of construction of the cast-in-concrete reactor does not lend itself readily to a design involving a very large number of turns. Consequently for circuits carrying very low currents the disk-coil air-core or the iron-core reactor is more economical.

There being no iron present in the magnetic circuit of the air-core reactor, its characteristic curve is a straight line; that is, its reactance voltage increases in exact proportion to the current, regardless of the value of the same. Furthermore, as there is no hysteresis, the flux does not lag behind the current but is always exactly proportional to it, and the full value of the reactive effect is realized.

Position of Reactor in Circuit

Reactors may be connected in either the high-tension supply circuit or between the transformer and furnace. Usually, if the current in the low-voltage circuit is of the order of 1500 amperes or higher, it is more economical, considering the cost of reactors, switches and connections, to put the reactors in the high-voltage circuit. This will also depend, however, on the voltage of the circuit and the amount of reactance required. No absolutely general rule can be given.

Conclusions

When reactance in addition to the normal value is required in an electric furnace circuit it may be obtained by increasing the reactance of the transformer, by suitably arranging the conductors, or by inserting reactance coils. The amount of reactance that can be obtained by the first two methods is limited, and they should only be used when the reactance is desired cotinuously in the circuit.

When varying values of reactance are required during different portions of the operating cycle, reactance coils should be utilized. As the reactance is desired principally as a current limit, air-core reactors should be used wherever possible. Obviously, it would be advantageous if the reactance of the coil increased for current values above normal, as it would then be possible to have a fairly high power factor at normal load and still limit the maximum short-circuit current to a low value. The reactance voltage of the air-core reactor increases in direct proportion to the current flowing, while that of the iron-core type increases at a lower rate than the current. Obviously, the air-core reactor is preferable for furnace work.

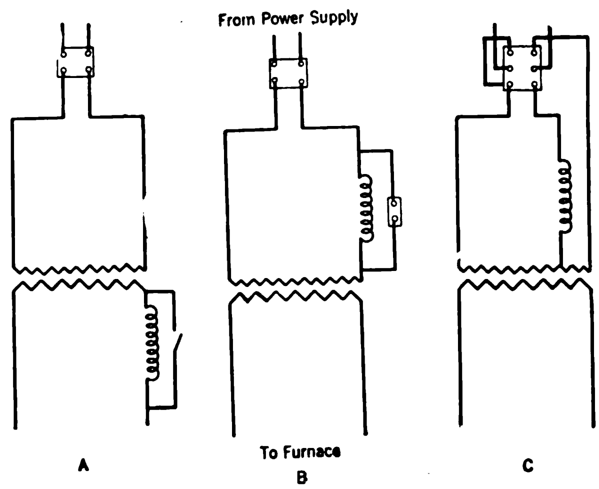

Fig. 8—Various Arrangements of Reactors in Electric Furnace Circuits

In view of the considerations stated above, the cast-in-concrete air-core reactor, being substantial, efficient, and fire-proof, is in the opinion of the writer, the most suitable reactor for electric furnace circuits.

A NEW FUEL FLUID

Jerome Alexander, in a paper read before the American Chemical Society at St. Louis, April 15, announced the discovery of a new fuel fluid, greater in heat value than either coal or present fuel oils. He asserted that the fluid would prove valuable to navigation, permitting a wider cruising radius, and could be used for smoke screens. The new fuel utilizes coal waste and cheap tars, mixed by a secret process.

Automatic Control of Arc Furnace Electrodes

BY J. A. SEEDE

Engineer, General Electric Co., Schenectady, N. Y.

ALL electric furnaces with the exception of a certain special type of resistance furnace, the induction furnace, require electrodes for conducting current to the active zone. These electrodes are either fixed or movable and, with very few exceptions, are made of carbon or graphite.

In those furnaces using fixed electrodes, as in a graphitizing furnace, or in certain smelting furnaces, where the electrodes are moved only at long intervals as in an iron smelting furnace, the power input is controlled by varying the voltage applied to the electrodes by one of several available methods.

The most important class, at least from the standpoint of numbers, comprises those furnaces of the arc type in which control of the power input is obtained by moving the electrodes up and down, or in and out, as the case may be. These may be divided into two classes; the first embracing furnaces operating on a continuous cycle and normally of comparatively large capacity, such as calcium carbide and various ferro alloy furnaces; the second comprising furnaces for melting steel and other metals which operates on an intermittent cycle and range normally in capacity from 4500 kw. to 75 kw. and smaller.

The power input of furnaces of the first class may easily be kept within 1 per cent either side of the average while several times this value must be allowed furnaces of the second class, especially in the case of steel melting.

The various electric furnaces for melting and refining may be grouped in the following divisions:

Case 1—One Movable Electrode—One Arc

For the control of one electrode all that is required is a single contact-making current relay with auxiliary contactors, relays, etc. On circuits with excessive voltage fluctuations or where furnace troubles are experienced from careless operators and poor scrap, additional protection may be desirable, such as may be obtained by addition of a balanced voltage relay. In this division may be grouped single electrode furnaces for various smelting applications, the single-phase Girod and Snyder steel melting furnaces and the Booth, Detroit, and Weeks brass melting furnaces.

Case 2—Single-phase Two Movable Electrodes—Two Arcs In Series

With this arrangement current control of both electrodes might quickly result in one arc absorbing all the voltage and forcing the other electrode into the charge, destroying the heat balance and radiating too much heat to the wall. To prevent this we control one electrode by current in that electrode and the other electrode by the voltage drop across the arc. The first control virtually adjusts the total length of both arcs while the second control maintains constant the length of the second arc. In case of variable voltage control another feature is required to maintain the arc voltage constant at one-half total voltage, that is a balanced voltage relay.

This division comprises single-phase, two-electrode smelting furnaces and the single-phase Heroult furnace.

Case 3—Two-Phase—Two Movable Electrodes—Two Arcs

This is the well known connection of using two-phase, three wires, or its electrical equivalent, the bottom being the neutral. This arrangement uses practically the same control as two single-phase furnaces, each having one movable electrode, in one shell and therefore requiring two current relays.

In this division are the Snyder, Greene, Gronwall-Dixon, Vom Baur, Rennerfelt and Greaves-Etchells melting furnaces.

Case 4—Two-Phase—Four Movable Electrodes—Two Arcs In Series Per Phase

This arrangement is electrically the same as Case 2, having two groups in one shell. The Stobie steel melting furnace is practically the only representative of this class.

Case 5—Three-Phase—Three Movable Electrodes—All Arcs In Series

As all electrodes are above the charge equal current will give balanced voltage and power, three current relays being sufficient. In this division are almost all three-phase smelting furnaces and the three-phase Heroult and Stassano furnaces.

Case 6—Three-Phase—Three Movable Electrodes—With Bottom Connections

In this case control will be obtained by having three elements of case 1, that is, practically three single-phase furnaces in one shell. This connection is almost wholly limited to the three-phase Girod melting furnace and special smelting furnaces.

While close control of the power input is desirable, there are other factors to be considered, such as furnace maintenance, electrode consumption, quality of product and unecessary labor charges, in addition to strains on generating and transforming apparatus, all of these being improved by using automatic electrode control. It is admitted that attempts have been and will be made to control furnaces by hand, but a brief consideration of some of the inherent disadvantages of hand control should convince any operator of the false econ-

Presented at the Boston Meeting of the A. I. E. E., April 9, 1920.

omy of such arrangement. These factors might be listed as follows:

1. Power Input.
2. Furnace Maintenance.
3. Electrode Consumption.
4. Labor Charges.
5. Quality of Product.
6. Upkeep of Transformers.

All of these items successfully combined have bu one meaning that is, continuous operation with a minimum of interruptions and accordingly, minimum operating costs.

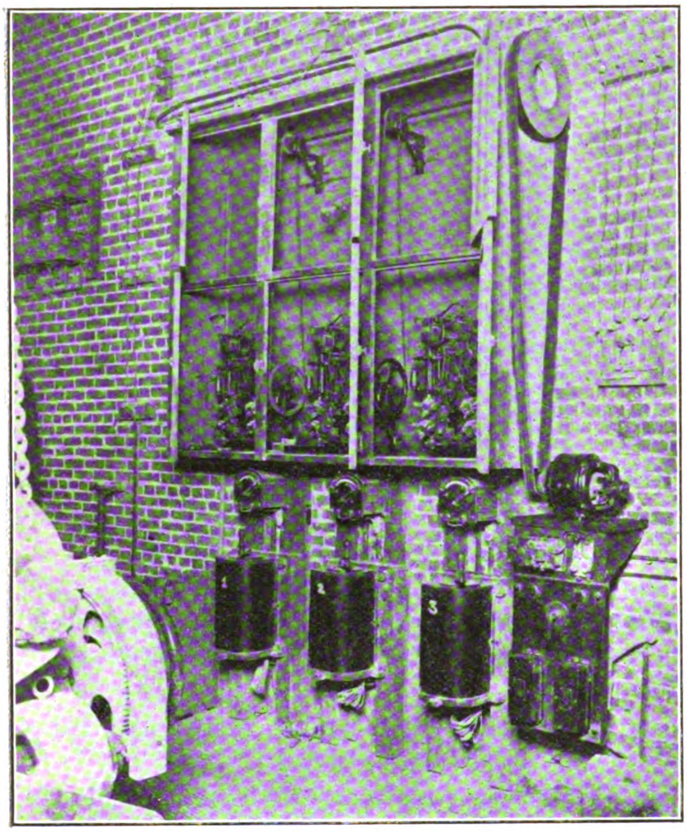

Fig. 1—Three-Phase Thury Regulator

1. *Power Input.* In operating an electric furnace it is desirable to keep all surges, momentary and sustained, within the closest reasonable limits, as in practically all cases these surges have a definite bearing on the cost of power and, even when this effect is a minimum, undue surges affect other power consumers on the same line and frequently result in complaints which tend to cause prejudice against electric furnaces in general. These surges also affect other items such as, furnace maintenance, electrode consumption, quality of product and upkeep of apparatus, all of which are of sufficient importance to warrant systematic efforts to reduce this evil to a minimum. The momentary surges are limited by the electrical characteristics of the circuit while the duration of the sustained surge is determined by the operation of the automatic control.

In those power contracts where power is purchased at a fixed price, the importance of keeping the load factor close to 100 per cent need not be emphasized and this has a direct bearing on the production that can be obtained from a given equipment. In any installation, there are a number of fixed charges and the higher the load factor the lower will be the amount of these charges per unit of material produced.

2. *Furnace Maintenance.* The effect of sustained surges is to carry the current density far above the designed carrying capacity of the electrode holders and conductors. As the heating varies directly with the square of the current, a current increase of 50 per cent will increase the heating 125 per cent above normal and shorten the life of any current-carrying contact surface. The heat that is radiated directly from the arc to the roof and side walls when the electrodes are raised, unnecessarily shortens the already brief existence of those important furnace parts.

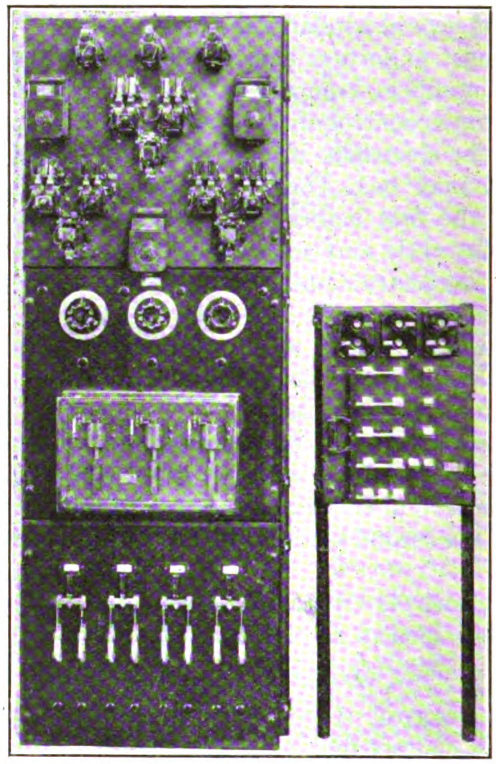

Fig. 2—Three-Phase General Electric Regulator

3. *Electrode Consumption.* There seems to be little question that electrode consumption is increased when the power is permitted to vary over wide ranges. Excessive or long continued surges tend to cause overheating at the weak spots in the electrode with consequent spalling and cracking.

4. *Labor Charges.* In these times when all labor is scarce and high-priced, the practise of paying a man 50 cents an hour to sit on a stool watching one or more meters and manipulating controlling devices in an attempt to keep the power input within reasonable limits is an economic waste that can have no reasonable defense. No matter how sincere the worker may be

in his attempt to meet conditions imposed, he is, after all, only human and his will soon becomes deadened by the tiring effect of watching a meter needle in constant motion.

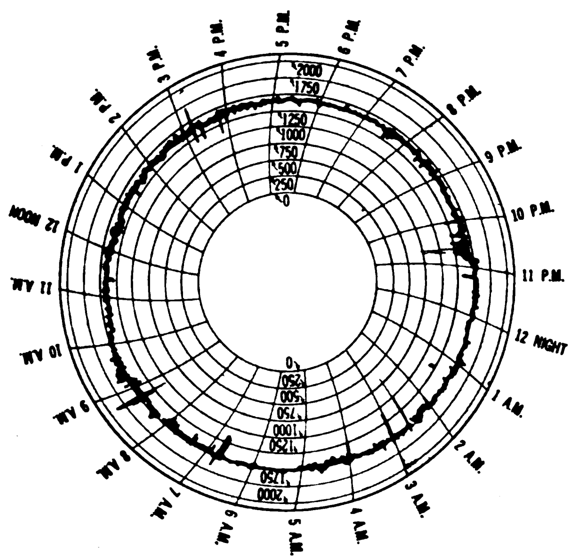

Fig. 3—Twenty-four Hour Chart of Three-phase, 1500 kw. Ferro-Chromium Furnace Controlled by General Electric Regulator

Assume that he can keep his eyes fixed continuously on the needle (which is hardly possible) and there is a sudden change in the furnace. The eye conveys the message to the brain, the brain sends an impulse to the hand, the hand turns a wheel or throws a switch and

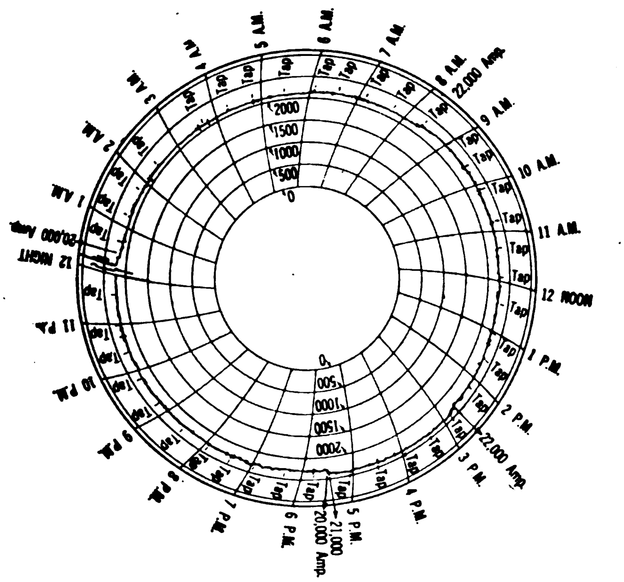

Fig. 4—Twenty-four Hour Chart of Three-phase, 3000. kw. Calcium Carbide Furnace Controlled by General Electric Regulator

the electrode position is regulated, all of which takes appreciable time and if he happens to be sleepy or looking in some other direction, the adjustment is accordingly delayed.

With the contact-making meter following the impulses continuously, the automatic regulator throws the switch as soon as the change takes place and the electrode is moved almost instantly. Assuming that an operator can manage two or more electrodes (which is true only in unusual cases), with continuous operation, at 50 cents per hour there will be a labor charge at the end of the year over $4000, an amount that will pay for several automatic electrode regulators.

5. *Quality of Product.* The effect on the quality of the product will vary with different processes but in certain cases, such as steel melting, it would only require plunging the end of the electrode in the bath several times to add enough carbon to upset the analysis and cause considerable delay in bringing it back to the desired point. Also if the electrodes contained certain impurities these could be transferred to the steel and cause additional trouble.

In addition the long flaring arc that exists when the electrode is raised too high will volatilize part of the slag which will condense on the roof and side walls and assist in their destruction by fluxing.

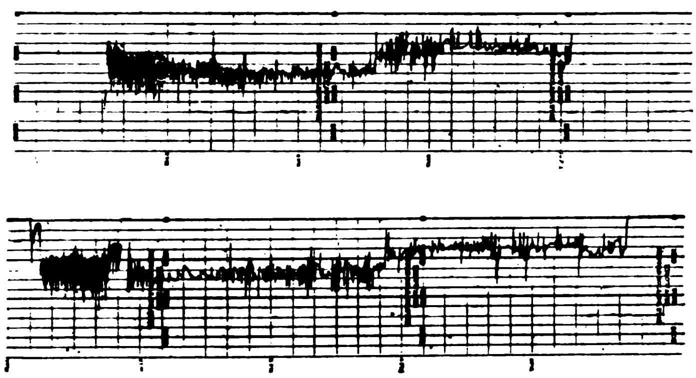

Fig. 5—Two Charts of Heats in 1500-kw. Three-phase. Steel-Melting Furnace Starting with Cold Charges

6. *Upkeep of Transformers.* While the average transformer stands considerable abuse it has its limitations and will be in better shape to meet emergency conditions if it has not been subjected to the strains and overheating of a large number of surges.

General

The problem of maintaining the position of an electrode with its supporting mechanism and flexible conductors is not a simple one even against another stable electrode, be it the surface of a molten charge or another carbon or graphite electrode, and when the second electrode is the surface of a heap of various pieces of solid metal, continually changing under the action of the arc, the difficulties are considerably increased.

There is considerable difference whether or not the metal is molten or solid. From the surface of molten metal there is a continuous spray of small metallic particles which make it a simple matter to establish the arc sometime before the electrode touches the metal, but with solid metal the electrode must practically

touch the charge before the arc is struck and then the electrode must be drawn away quickly so as to minimize the surge that invariably follows. This is the condition met in the first part of melting down a charge of steel scrap and is a trying time to all parts of the equipment, but is also the time when the automatic control pays for itself many times.

To accomplish these results and keep the power input within set limits means an apparatus that will move

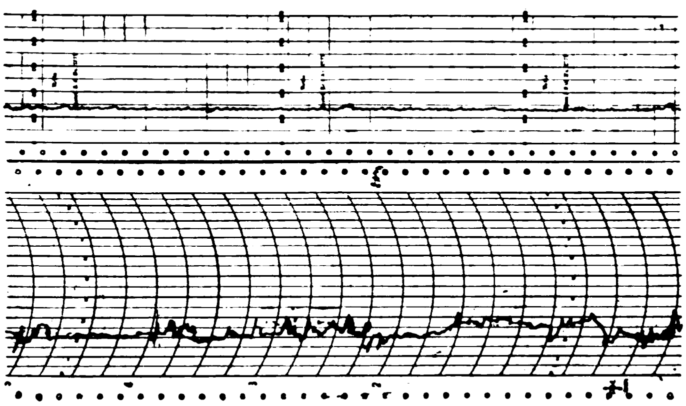

Fig. 6—Comparative Charts of Similar Furnaces, the Lower One, Using Hand Control and the Upper One Automatic Control, Furnace Quiet

the electrode quickly from the old position to the new one and then manitain the new position without overrunning. To do this without extraordinary stresses on the apparatus means average electrode speeds of approximately 12 in. per minute, or less. This is considered normal automatic operation but abnormal or emergency operation, such as changing a broken electrode during a heat, a hand-operating speed of three to ten times this figure is desirable, if not absolutely necessary.

There are two methods of electrode regulation, the intermittent, in which the electrode is moved by a series of small movements, and the continuous, in which the electrode is adjusted in one continuous motion and then stopped. The Thury regulator belongs to the intermittent type while the General Electric regulator is of the continuous type, and both types have attained considerable success in the automatic control of arc furnace electrodes.

The apparatus used consists substantially of the following:

For each electrode there is provided a balanced relay, with adjustable damping, which is responsive to electrical changes in the furnace and controls, mechanically or electrically, the circuits of the motor having that electrode. The successful functioning of the control depends initially on a balanced relay, usually responsive to amperes but often to volts and occasionally to watts. This relay is provided with a dash pot which can be adjusted to vary the damping as may be required in different applications.

In the Thury regulator this relay engages a mechanical device for controlling the circuits of the electrode motor.

In the General Electric regulator this relay is provided with contacts, which control solenoid operated switches which in turn control the electrode motor circuits.

Safety devices giving additional protection against exterior disturbances are desirable, and one arrangement consists of shunt relays, excited by the voltage drop between electrodes and so arranged that upon failure of the furnace power supply the automatic control will be rendered ineffective and prevented from forcing the electrodes into the charge and causing damage to the apparatus.

This is done because the power supply to the electrodes and to the motor-generator sets supplying direct-current power are usually separate, and with the failure of the power supplied the electrodes, the automatic control would necessarily force the electrodes into the charge. By a simple connection this feature is rendered ineffective when the hand control is used so that the electrodes can be moved at will, regardless of the condition of the power circuit supplying the electrodes.

As stated before, the electrode movement must be positive, especially as to stopping, and this is preferably done by dynamic braking for which purpose a shunt-wound motor is preferred. It is understood that alter-

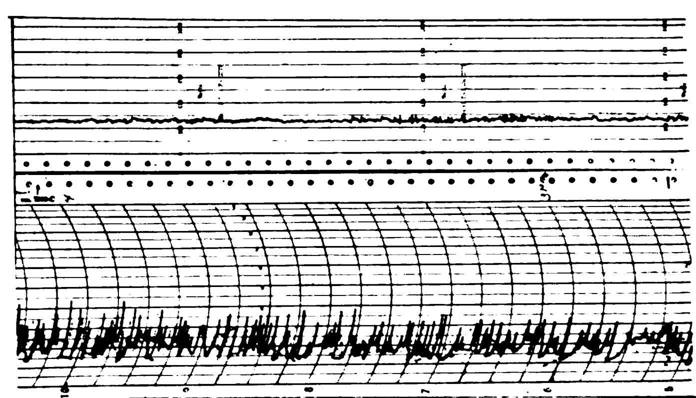

Fig. 7—Comparative Charts of Similar Furnaces, the Lower One Using Hand Control and the Upper One Automatic Control, Furnace Active

nating-current motors have been used for the successful control of electrodes, but this means solenoid brakes, and with all due respect to the perfection attained in those devices it is an additional feature that requires upkeep and is therefore opposed to the minimum simplicity.

The direct-current motor requires a source of d-c. power which may mean the added complexity of an added motor-generator set, but this is a small matter and usually direct-current power is available from a crane circuit.

The suggestion has been made that the furnace equipment would be simplified by operating alternating-current electrode motors from furnace circuits,

but this is not feasible for many reasons, such as drop in voltage with surges, rendering the motor weakest when needed, requiring voltage to be on electrodes when making electrode changes, etc.

With a reversing three-phase motor there would be required five wires per motor and the wiring for the brake solenoids, while with the d-c. motor four wires are required and no brake wiring.

The automatic control of the electrode is affected somewhat by power factor and occasionally references are made to furnaces operating with a power factor of 95 per cent. The normal furnace load is so much better than what is expected of industrial apparatus in general that we may reasonably protest against expecting such high figures and refer to the better results that will be obtained by arranging for approximately 90 per cent power factor. Many power companies are now penalizing power factors below 70 per cent, but such low power factors are not desirable for ordinary furnace work.

With 95 per cent power factor the reactance component is 31.2 per cent which gives a short-circuit current of 320 per cent. With 96 per cent power factor these figures are 43.6 per cent and 229 per cent respectively, while with 85 per cent power factor the corresponding figures are 52.7 per cent and 190 per cent. This means that the surges are 40 per cent higher on 95 per cent power factor over 90 per cent power factor and 20 per cent higher on 90 per cent as compared to 85 per cent power factor. From this it can be seen that 90 per cent power factor gives results that are a good compromise on surges and reactive component and it is recommended that this figure be kept in mind on all furnace installations, especially in small capacities.

The automatic electrode regulator has been used commercially in Europe for 25 years, and in this country about 15 years. Almost invariably it demonstrates to the user its value in effecting unforseen savings and bettering conditions, not the least being the maintaining of co-operation with the power company. With constantly increasing demands for power and increasing difficulty in meeting these demands, limitations must be maintained on power users and accordingly, with furnace users, the automatic electrode regulator will become more and more, a factor of first importance in the great field of electric arc furnace applications.

"REPRODUCTION NEW" MEANS HIGHER RATES

Possibility of rate increases of nearly 100 per cent for all public utility operators is seen in the decision of the United States Supreme Court upholding the "reproduction new" as the valuation basis for fixing railroad rates. The decision was made in the case of the Kansas City Southern Railroad against the Interstate Commerce Commission. According to press dispatches from Washington, the Supreme Court held the present value of physical property of the railroad should be accepted as the basis for determining rates. In most cases physical property of railroads, street car, telephone, electric light and power and gas companies of the country would cost nearly double their original values if reproduced today. Property value is the largest item considered in rate fixing. Other items are operating cost and percentage of profit. From the valuation must be deducted the amount of depreciation.

In fixing the new schedule of rates for Bell telephone companies operating in Indiana the public service commission recently refused to accept the "reproduction new" basis offered by the company, but based the new rates on the reproduction values of companies' various physical properties throughout a period of five years. Many other rate cases have been decided by the commission on the same basis.

Conditions similar to those created in Indiana by the basis established by the Supreme Court exist in various other states. Little doubt is entertained by rate experts that the railroad decision will be so far-reaching as to affect every form of industry over which a government institution possesses rate-making authority.

Value of rolling stock of the Kansas City Southern Railroad was not offered for consideration by the Supreme Court, according to dispatches, but the court found for the appellant on its present-day cost of right-of-way and terminals contention.

The Indiana commission has followed the rule established in several other states of basing valuation estimates on an average of production costs throughout a period of five years. In the case of the Bell telephone companies the commission took an average of production costs in the years from 1913 to 1918. Present-day material prices were held by the commission to be abnormal, and, therefore, not suitable to the formation of a sound rate-fixing estimate.

It is difficult to foresee the results of the establishment of the new basis of valuations. As far as rates are concerned it is quite clear that the "reproduction new" values of nearly all utilities would make rates nearly double present rates if a profit margin of 7 per cent is maintained.

If a telephone company's property cost $100,000 five years ago, it is worth today $200,000 in a fair round figures estimate, it is asserted. That is, it would cost that much to reproduce it today. Without confusing the figures with depreciation expense, rates for that company, based on the original valuation, would amount to 7 per cent of $100,000, plus the cost of operation. That would mean upward of $7,000. The same percentage of profit on a $200,000 valuation would mean about $14,000, plus the cost of operation, which would be the same under either valuation. Thus it is seen that the new valuation as against the old system would mean rate increases of more than 95 per cent. Even in cases where the five-year-period valuation basis is used, the new valuation would mean rate increases of more than 75 per cent, experts say.—*Telephone Engineer*.

THIRTY-SIXTH ANNUAL CONVENTION

The Thirty-Sixth Annual Convention of the American Institute of Electrical Engineers will be held at "The Greenbrier," White Sulphur Springs, West Virginia, June 29 to July 2, 1920.

In both the selection of the convention headquarters and in the program proposed the Convention Committee feels that the Annual Convention for 1920 should prove a fitting climax to an Institute year of unprecedented activity and advancement. Seven technical sessions are scheduled at which subjects of particular interest in many phases of present day practise will be presented through the medium of a most comprehensive collection of papers. Ample opportunity has also been provided for recreation and entertainment by leaving the afternoons open for the many entertainment features which are being arranged by the Convention Committee, including dancing, teas, card parties and other special functions for the ladies, and the usual golf and tennis tournaments, baseball and other special events.

Location

The selection of White Sulphur Springs as the convention meeting place is a most happy one. It is located equally distant in an air line from New York, Toronto, Chicago, St. Louis and Atlanta. Amid a peculiarly attractive environment on the slope of the Greenbrier Mountains, 2000 feet above sea-level, where it is never hot even in mid-summer, is situated "The Greenbrier," a new and magnificent hotel of modern steel construction, absolutely fireproof and equipped with every convenience. Every room is connected with a private bath. For those desiring quiet, there are 60 small cottages surrounding the hotel. In close proximity to the hotel there is an 18-hole golf course, 6250 yards long, one of the finest in the country, and an equally good nine-hole course. The new clay tennis courts are famed the country over. The new bath establishment is luxurious and complete. Every facility is offered guests to enjoy the same kind of baths as are given at European resorts. There is a fully equipped swimming pool, 50 by 100 feet. Over 100 miles of well-built track winding in and out through the mountain ridges lead those interested in horses and riding through some of the most beautiful scenery in the State. A fine stable is maintained, with thoroughbred hunters, jumpers, and horses for all occasions and there is a pack of hounds for drag hunts. Those interested in motoring will find the roads leading through White Sulphur Springs in excellent condition and motoring from New York, Philadelphia and Washington is steadily increasing.

Convention Sessions

A tentative program has been arranged which calls for the opening of the Convention on Tuesday morning, June 29, with the Annual Presidential Address, by President Calvert Townley, followed by the introduction of the President-elect. The remainder of the session will be devoted to the presentation and discussion of the Annual Reports of the Technical Committees. Six sessions for the presentation of papers under the auspices of various technical committees have been mapped out as indicated in the program of sessions.

TENTATIVE PROGRAM OF TECHNICAL SESSIONS

Tuesday, June 29—Opening Session:

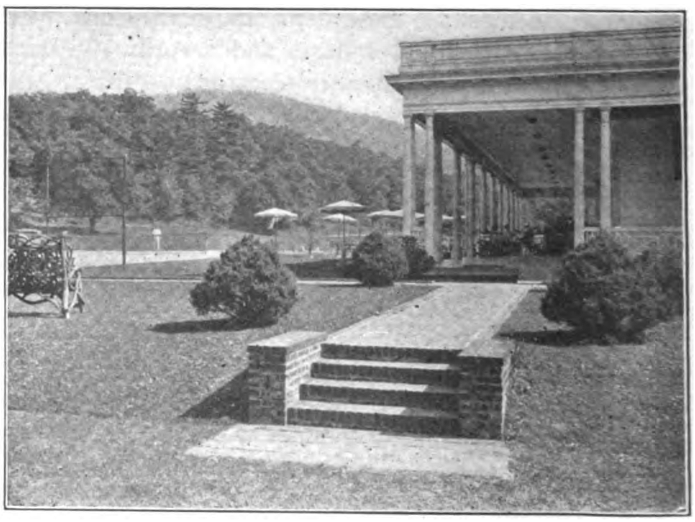
1. *President's Address*, by Calvert Townley.
2. *Report of Technical Committees.*

Wednesday, June 30—Electrical Machinery Session:

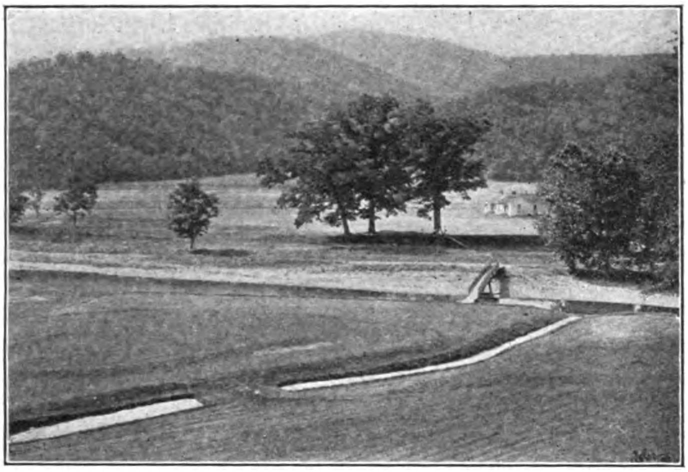
3. *Classification of Large Steam Turbo Generator Failures* by Philip Torchio.
4. *Ventilation and Temperature Problems in Large Turbo Generators* by B. G. Lamme.
5. *Temperatures in Large A-C. Generators* by W. G. Foster.
6. *Some Practical Experience with Embedded Temperature Detectors in Large Generators* by C. J. Fechheimer and F. D. Newbury.
7. *Eddy Current Losses in Armature Conductors* by R.E.Gilman.

Miscellaneous Session:

8. *The Corona Voltmeter and the Electric Strength of Air* by J. B. Whitehead and T. Isshiki.
9. *Reactive Power and Magnetic Energy* by Joseph Slepian.
10. *Theory of Speed and Power Factor Control of Large Induction Motors by Neutralized Polyphase Alternating-Current Commutator Machines* by John I. Hull.
11. *High-Tension Insulator Porcelain* by W. D. A. Peaslee.



TENNIS COURTS AND CLUB HOUSE AT "THE GREENBRIER"



On the Links at "the Greenbrier"

Thursday, July 1—Protective Devices Session:

12. *The Use of Reactors on Large Central Station Systems* by R. F. Schuchardt.
13. *Stability of High-Power Generating Stations* by C. P. Steinmetz.
14. *Voltage Stresses in Reactors in Service* by F. H. Kierstead and Royal Meeker.
15. *Calculation of Magnetic Force on Disconnecting Switches* by H. B. Dwight.
16. *Stresses in Conductors Carrying Heavy Currents* by I. W. Gross.

Electric Welding Session:

17. *Design of Constant-Current Generators for Arc Welding* by K. L. Hansen.
18. *Automatic Arc Welding Apparatus* by S. R. Bergman and H. L. Unland.
19. *Arc Welding Machines of the Wilson Welder and Metals Company* by Alex. Churchward.
20. *Characteristics and Performance of Arc Welding Machinery* by A. M. Candy.
21. *Arc Welding Machinery of the U. S. Light and Heat Corporation* by W. H. Turbayne.
22. *Recent Developments in Electro-Percussive Welding* by D. F. Miner.

Power Factor Session:

23. *Report of Joint Committee.*
24. *Polyphase Power Factor* by F. C. Holtz.
25. *Power Factor Improvement Dependent upon Adequate Metering* by Will Brown.
26. *Power Factor in Polyphase Systems* by F. B. Silsbee.
27. *Power Factor and Unbalance on a Polyphase System* by C. J. Fechheimer.
28. *Polyphase Power Factor* by H. L. Wallau.
29. *Polyphase Power Factor* by P. M. Lincoln.
30. *Polyphase Power Representation by Means of Symmetrical Coordinates* by C. L. Fortescue.
31. *Measurement of Power Factor on Unbalanced Polyphase Circuits* by R. D. Evans.
32. *Polyphase Power Factors and Unbalanced Loads* by Philip Torchio.
33. *Power Factor in Polyphase Circuits* by W. H. Pratt.

Friday, July 2—Excitation Session:

34. *Considerations Which Determine the Selection and General Design of an Exciter System* by J. T. Barron and A. E. Bauhan.
35. *Factors in Excitation Systems of Large Central Station Steam Plants* by A. A. Meyer and J. W. Parker.
36. *Exciters and Systems of Excitation* by H. R. Summerhayes.
37. *The Application of D-C. Generators to Exciter Service* by C. A. Boddie and F. L. Moon.
38. *Exciter Practise in the Northwest* by J. D. Ross.
39. *Generator Excitation Practise in the Hydroelectric Plants of the Southern California Edison Company* by H. H. Cox and H. Michener.

Abstracts of most of the Convention papers appear elsewhere in this issue of the Journal. Papers scheduled for the Miscellaneous session were printed in full in the May Journal.

Advance copies of complete papers may be obtained as soon as available by applying at Institute headquarters.

Transportation

While the following daily schedule is now in effect and will probably remain so until after the Convention, members are advised to consult their local ticket agents relative to trains and fares to and from White Sulphur Springs. Particular emphasis is placed upon the necessity for engaging Parlor Car and Sleeping Car accommodations at the earliest possible date.

New York	$14.22	$25.60
Chicago	19.15	32.30
Cincinnati	10.60	17.18
Pittsburgh	13.15	23.67
St. Louis	19.92	35.86
*Atlanta	17.79	34.14
Detroit	14.80	26.64
Washington	7.37	14.40

These fares do not include War Tax.

Sleeper and Parlor Car charges are additional.

*Via Lynchburg.

Rates at "The Greenbrier"

American Plan

Single Rooms	Two or More sharing bath	Two or More in Room without bath
$10.00 per day	$9.00 per day	$7.00 per day

Reservation of Accommodations

Accommodations at "The Greenbrier" should be reserved as early as possible, by writing or telegraphing directly to the hotel. All communications should be addressed to: "The Greenbrier," White Sulphur Springs, W. Va.

PACIFIC COAST CONVENTION

The Ninth Annual Pacific Coast Convention of the A. I. E. E. will be held in Portland, Oregon, July 21-24, 1920, under the auspices of the Portland Section. Headquarters at the Multnomah Hotel.

A tentative program has been arranged as follows:

Wednesday, July 21

9:30 A. M.

1. *Address* by President Calvert Townley.
2. *Factors Controlling the Design and Selection of Suspension Insulators*, by W. D. A. Peaslee, Electrical Engineer, Jeffery-Dewitt Insulator Company.

2:00 P.M.

3. *Unit Voltage Duties in Long Suspension Insulator Strings*, by Professor Harris J. Ryan and H. H. Henline of Leland Stanford Jr. University.
4. *Electrical Characteristics of the Suspension Insulator at the Higher Voltages*, by F. W. Peek, Jr., Consulting Engineer, General Electric Company, Pittsfield, Mass.

7:30 P.M.

Automobile tour over scenic boulevards of the city.

Thursday, July 22

9:30 A.M.

5. *Electrification of Railroads*, by Reinier Beeuwkes, Electrical Engineer, C. M. & St. P. Railroad.
6. *Bridge Methods for Alternating-Current Measurements*, by D. I. Cone, Engineering Dept., Pacific Telephone and Telegraph Company.

2:00 P. M.

7. *Sawmill Refuse, Fuel Oil and Pulverized Coal*, by Darrah Corbet, Chas. C. Moore and Company.

7.30 P. M.

General discussion on Institute Welfare.

Friday, July 23

9:30 A. M.

8. *Power Factor Correction on Distribution Systems*, by D. M. Jones, General Electric Company, Schenectady, N. Y.
9. *Use of Special Steels in Pressed Steel Transmission Line Fittings*, by L. R. O'Neill, Chief Engineer, Maryland Pressed Steel Company.

In addition to the presentation of the papers scheduled above the Convention Committee has arranged for various entertainment features including a Golf Tournament for the John B. Fisken Cup to start at 1 p.m. on Friday, a trip over Columbia River Highway starting at 2 p.m. on the same day and followed by a banquet at the Crown Point Chalet at 7. p.m.

Saturday, July 24

Tours of inspection to the steam and hydroelectric plants of the Portland Railway, Light and Power Company and the Northwestern Electric Company and to other points of interest in and around Portland are arranged for Saturday July 24.

Special entertainment will be provided for the visiting ladies.

ANNUAL MEETING AND EDISON MEDAL PRESENTATION

The annual meeting of the A. I. E. E. was held at Engineering Societies Building, New York, on Friday evening, May 21, 1920, President Calvert Townley presiding.

The annual report of the Board of Directors was presented in abstract by Secretary Hutchinson. Pamphlet copies of this report had been printed in advance and are available to any member upon application to the Secretary of the Institute.

The report of the Committee of Tellers on the election of officers was then presented and in accordance therewith President Townley announced the election of the following officers, whose terms will begin August 1, 1920: *President*, Arthur W. Berresford, Milwaukee; *Vice Presidents*, E. H. Martindale, Cleveland, Charles Robbins, Pittsburgh, C. S. Ruffner, New York, C. E. Magnusson, Seattle, C. S. McDowell, U. S. Navy, L. T. Robinson, Schenectady; *Managers*, E. B. Craft, New York, Harold B. Smith, Worcester, James F. Lincoln, Cleveland; *Treasurer*, George A. Hamilton, Elizabeth. These officers, together with the eleven holdover members, will constitute the Board of Directors for the year beginning August 1st.

The report of the Committee of Tellers upon the ballots cast by the membership on the proposed constitutional amendments was then presented. These proposed amendments provided that the membership be grouped into geographical districts and that one Vice President be elected from each district for a term of two years.

The report shows that 3936 ballots were cast in favor of the amendments and 36 in opposition. President Townley thereupon declared the amendments adopted. Accordingly, they will become effective in connection with the election in the spring of 1921.

The Edison Medal presentation ceremonies followed immediately after. The program consisted of a statement regarding the origin and history of the Edison Medal by Dr. Carl Hering, Chairman of the Edison Medal Committe, an address relating to the achievements of Mr. W. L. R. Emmet, the medalist, by Past-President H. W. Buck, the presentation of the medal by President Townley and the response of Mr. Emmet. A more detailed report will be published later.

REPORT OF COMMITTEE OF TELLERS ON ELECTION OF OFFICERS

To the President,

American Institute of Electrical Engineers.

DEAR SIR:

This committee has carefully canvassed the ballots cast for officers for the year 1920–1921. The result is as follows:

Total number of ballot envelopes received		4064
Rejected on account of bearing no identifying name on outer envelope, according to Art. VI, Sec. 34, of Constitution	74	
Rejected on account of voter being in arrears for dues on May 1, 1920, as provided in the Constitution and By-laws	88	
Rejected on account of ballot not being enclosed in inner envelope, or being improperly marked, or on account of inner envelope bearing an indentifying name, according to Art. VI, Sec. 34, of the Constitution	11	
Rejected on account of having reached the Secretary's office after May 1, according to Art. VI. Sec. 34, of the Constitution	39	
		212
Leaving as valid ballots		3852

These 3852 valid ballots were counted, and the result is shown as follows:

For President

A. W. Berresford	3007
C. E. Skinner	479
William McClellan	87
A. M. Schoen	84
N. A. Carle	82
J. B. Fisken	18
Blank	95

For Vice-Presidents

E. H. Martindale	3536
Charles Robbins	3512
C. S. Ruffner	3462
C. E. Magnusson	3433
C. S. McDowell	3352
L. T. Robinson	3307
J. B. Whitehead	519
Philip Torchio	376
H. P. Liversidge	295
W. S. Lee	290
*Robert Sibley	70
Blank	960

*Candidate withdrew prior to printing of ballots.

For Managers

E. B. Craft	3715
Harold B. Smith	3710
James F. Lincoln	3698
Blank	433

For Treasurer

George A. Hamilton	3724
Blank	128

Respectfully submitted,

(*Signed*) EDW. J. K. MASON
Chairman

WILLIAM P. ABENDROTH
CHAS. M. FULK
P. C. PAQUETTE
PHILANDER NORTON

REPORT OF COMMITTEE OF TELLERS ON AMENDMENTS TO THE CONSTITUTION

To the Board of Directors,
American Institute of Electrical Engineers.

GENTLEMEN:

This committee has canvassed the ballots cast on the amendments to the Constitution submitted to the membership in a circular letter dated March 15, 1920, and the result is as follows:

Total number of envelopes received		4508
Of these the following were rejected in accordance with the Constitution and By-laws for the reasons given below:		
No identifying name on envelope	380	
In arrears for dues on May 1, 1920	76	
Received after May 14, 1920	1	
Blank ballots	7	
Ballots rejected because of improper marking, etc.	72	
Total invalid ballots	536	
Leaving as valid ballots		3972

These valid ballots were counted and the result is as follows:

In favor of adoption of amendments	3936
Against adoption of amendments	36

Respectfully submitted,

Committee of Tellers.

(*Signed*) EDW. J. K. MASON,
Chairman

WILLIAM P. ABENDROTH
CHAS. M. FULK
PHILANDER NORTON
P. C. PAQUETTE

JOHN FRITZ MEDAL PRESENTED TO ORVILLE WRIGHT

The presentation of the John Fritz Medal to Orville Wright took place at a meeting in the Auditorium of the Engineering Societies Building, May 7th, 1920. Mr. Charles F. Rand presided and, after calling the meeting to order, announced the award of the John Fritz medal to Mr. Orville Wright for his achievement in the development of the airplane. Mr. Rand explained the origin and establishment of the medal in 1902 in honor of John Fritz of Bethlehem, Pa., and read the list of distinguished men to whom this medal had been previously awarded.

The medal is awarded annually by a Board appointed by four National Engineering Societies,—the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers and the American Institute of Electrical Engineers.

Mr. Rand introduced Major-General George O. Squire, who described Mr. Wright's early works in connection with the test and purchase of the first Wright airplane by the United States Government. Colonel Edward A. Deeds, the next speaker, described the early life of the Wright brothers and the many struggles and discouragements which they experienced before producing a practical airplane.

Prof. C. A. Adams then presented Mr. Wright with the medal and diploma, on which is inscribed the record of the award with the signatures of all the members of the Board of Award. Mr. Wright responded briefly, expressing his appreciation of the honor conferred upon him and acknowledging the help and inspiration he had received from many of his predecessors in aeronautics.

MEMORIAL MEETING FOR ANDREW CARNEGIE

On Sunday afternoon, April 25, at 3:30 p. m., a meeting was held in memory of the life and work of Andrew Carnegie at the Engineering Societies Building, 29 West Thirty-ninth Street, New York. The meeting was under the auspices of the Author's Club, the New York Public Library, the Oratorio Society, Saint Andrew's Society and the United Engineering Society. The meeting was opened by an invocation by the Rev. William Pierson Merrill.

Mr. J. Vipond Davies, Presiding Officer, after some introductory remarks read letters of tribute from Ex-president Taft, Viscount Morley, Viscount Brice and Sir Oliver Lodge, after which Dr. John H. Finley delivered an address, in which he told of many incidents in the life and work of Andrew Carnegie. Dr. Finley's address was followed by a selection, "Peace Hymn of the Republic", rendered by the Oratorio Society.

Mr. Elihu Root gave an address in which he traced the course of Mr. Carnegie's benefactions. The meeting concluded with the "Hallelujah Chorus", rendered by the Oratorio Society.

The memorial services were under the auspices of a Committee of Arrangements, which included Walter Damrosch, J. Vipond Davies, Cleveland H. Dodge, John Erskine, Alex. C. Humphreys, Rossiter Johnson, George F. Kunz, Lewis Cass Ledyard, Henry Moir, Charles F. Rand, Calvin W. Rice, Charles M. Schwab.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

AMERICAN DELEGATES ATTEND MEETING OF ADVISORY COMMITTEES IN BRUSSELS

Meetings of the Advisory Technical Committees of the International Electrotechnical Commission were held in Brussels March 27th to April 1st. The meetings were attended by delegates from eight national committees—Belgium, France, Great Britain, Holland, Italy, Spain, Switzerland, and the United States. There were about 40 delegates in all.

Although official decisions of the Commission are made only in plenary meetings, much of the work of the Commission is accomplished in the meetings of the Advisory Committees. Four of the Committees met at Brussels, namely: Rating, Definitions, Graphical Symbols, and Standard Voltages.

The meetings were attended by six American delegates—Messrs. C. O. Mailloux, C. E. Skinner, H. M. Hobart, A. H. Moore, L. W. Chubb, and P. G. Agnew. Dr. Mailloux is President both of the International Electrotechnical Commission and of the United States National Committee.

Rating. The Advisory Committee on Rating was presided over by Mr. Guido Semenza of Italy. The principal results of the meeting of this committee were the acceptance of:

1. The hot-spot principle as a basis of standardization. It was agreed, however, that the *working* rules should contain only

values of limiting observable temperature and temperature rise, and not the actual hot-spot values.

2. The classification of insulating materials. This classification is the same as the present A. I. E. E. rules with the addition of a new class, to be known as class "O", of unimpregnated cotton and similar materials.

3. The classification of methods of measurement, is the which same as that of the A. I. E. E. rules.

At the request of the American delegates the question of the terminal marking for transformers was deferred with the understanding that the American committee would submit a scheme sufficiently comprehensive to include all classes of apparatus and machinery.

Definitions. This committee held joint sessions with the committee on Symbols, under the presidency of Professor Janet of France. Definitions of about 60 terms were approved. These are terms which have been before the national committees for several years. There was considerable discussion as to advisability of attempting the preparation of a fairly complete International Electrotechnical vocabulary. Such vocabularies have been prepared by the national committees of France, Holland, and Italy. It was decided that these might serve as a basis of an international vocabulary, and a special committee was authorized for actively undertaking the work of its preparation. It is planned that this special committee shall hold its first meeting in Zurich.

Objection was received to the use of the word "gauss" as the unit of both magnetic force and magnetic induction. The question of the name for the unit of magnetic force was referred to the national committees.

A resolution was unanimously passed requesting the national committees to use their influence to prevent the formulation and introduction into use of electrotechnical terms which might ultimately present serious obstacles to international agreement.

Symbols. The Italian graphical symbols which had been formally submitted by the Italian National Committee at a previous meeting, were taken as a basis for discussion. The comprehensive list prepared by the British Engineering Standards Association, and Mr. Cheney's paper in the JOURNAL of the A. I. E. E., for February, 1920, which embodied the work of an A. I. E. E. sub-committee, were used as supplementary documents. Agreement was reached upon a list of about 100 symbols.

Standard Voltages. Owing to variety of circumstances, a great many voltages are now in use in Europe, and in the absence of standardization work, other voltages are being added. The European delegates felt strongly that immediate work should be done on two subjects—the standardization of voltages up to about 50,000, and the standardization of specifications for pin insulators. Some tentative proposals were formulated for the consideration of the various national committees. In informal conversations it was urged upon the American delegates that it would be very desirable for a comprehensive statement of American practise, accompanied by proposals, to be prepared and forwarded for the consideration of the other national committees.

As the meeting was not a plenary one, the actions of the advisory committees are not official decisions of the International Electrotechnical Commission. They are now before the national committees for study before official action is taken in a future plenary meeting.

The success of the meeting owes much to the very fine arrangements which were made by the Belgian committee, not only for the efficiency of the meeting but for the convenience and comfort of the visiting delegates. The President of the Belgian committee is Professor de Bast, and the Secretary is Mr. M. E. Uytborck. On Sunday, the delegates were conducted over the Yser battlefields by Capt. Leon Gerard, a member of the Belgian committee, and a great many of the devastated areas, including Courtrai, Nieuport, Dixmude and Ypres, were visited.

ENGINEERING SOCIETIES CALL NATIONAL ORGANIZATION CONFERENCE FOR JUNE 3-4, 1920

A call has been issued to the Engineering organizations of the United States for a conference on June 3rd and 4th, in Washington, D. C., for the consideration of the recommendations of the Joint Conference Committee of the Development Committees of the Founder Societies, relating to the formation of an affiliation of national and local engineering societies.

These plans call for the bringing into existence of a comprehensive organization or federation of the entire engineering profession; to place in the hands of a democratic body of engineers from existing engineering organizations of every kind all over the United States the authority and responsibility to speak for the engineering profession and to take united action on matters of common concern.

This movement is in harmony with a recommendation in the report of the Development Committee of the Institute, which was approved by the Board of Directors in August, 1919. The Board authorized the Development Committee to appoint delegates to a joint conference on this subject with the other Founder Societies. The Joint Committee submitted a report to the Board in October, 1919, which was published in the November PROCEEDINGS. In November the Board approved in principle the recommendations in this report and authorized the Institute's representatives to join with the conferees of such other societies as approved the report, in putting into effect the plan outlined.

The following has been adopted as a basis of representation at the Organizing Conference: Each national organization will be entitled to one delegate for 100 to 1000 members and an additional delegate for each additional 1000 members or major fraction thereof. Under this plan the Institute with a membership of over 11,000 would be entitled to eleven delegates.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

The Sixth National Exposition of Chemical Industries will be held in Grand Central Palace, New York, during the week September 20th to 25th inclusive. This will be the largest distinctly industrial exposition ever held, surpassing its own predecessors by one-third. It is to be divided into three special sections, one, the Electric Furnace Section, another the Fuel Economy Section, and the third a Materials Handling Section. The first will as its name implies be one of electric furnace exhibits; the fuel economy section will consist of exhibits of machinery and apparatus, furnaces, producers, stokers and all devices for the economic utilization or more efficient combustion of fuel. The possible exhaustion of our fuel reserves in the not far distant future and the present high cost of fuel makes this section one of much interest to all industrial plants. The Materials Handling Section will be a series of exhibits of machinery and equipment for the handling of material such as: conveying, transporting, elevating, included in this will be weighing, measuring and power transmission equipment. So important have these mechanical features become for all industrial plants due to the shortage and high-wage for man-power that an unusual interest is expected in this new Section.

The program for the exposition will have sessions on subjects the phases of which will be developed in the exhibits of these latter two sections. There will be sessions on chemical engineering for which an elaborate program is planned. Motion pictures which will have a keen interest for technical men will form part of the program, and there will be popular public addresses as well.

ARTHUR W. BERRESFORD

President Elect of A. I. E. E.

Mr. Arthur W. Berresford has been elected President of the American Institute of Electrical Engineers for the year beginning August 1, 1920, as announced in the report of the annual meeting published elsewhere in this issue.

Mr. Berresford was graduated from the Brooklyn Polytechnic Institute, 1892, and from Cornell University, 1893. He was actively engaged in electrical engineering work with operating and manufacturing companies until 1900, when he became identified with the Engineering Department of the Cutler-Hammer Manufacturing Company, and has remained continuously with that company, of which he is now Vice-President and General Manager.

Mr. Berresford became an Associate of the Institute in 1894 and was transferred to the grade of Fellow in 1914. He has been active and enthusiastic in promoting the welfare of the Institute having served as a member of many important committees and as chairman of several. He was a Manager 1909-12 and a Vice-President 1912-14. Mr. Berresford is eminently qualified for the presidency by engineering experience, executive ability, and service to the Institute.

ARTHUR W. BERRESFORD
President Elect of A. I. E. E.

ENGINEERING FOUNDATION

SEEKING LARGE ENDOWMENT

Based on the generous gifts and high purpose of Ambrose Swasey, Engineering Foundation has since 1915, maintained a liaison between engineers, as represented by the Founder and other societies, and scientific workers, as represented in National Research Council. Practical means for cooperation in research have been set up so that engineers in the numerous branches of the Profession may join with physicists, chemists, geologists, geographers, psychologists, doctors, biologists, educators and anthropologists, in the attack upon problems of common interest and in the exchange of knowledge.

Potential benefits for the whole Nation are very great, but these benefits cannot be gained without expenditure of effort and materials. Research workers must be supported. Equipment, materials, working places and traveling facilities must be provided. Since the benefits accrue to the professions, the industries and the public in general, support in large measure should come from general funds, such as those provided by endowments. Although engineers, like other professional men as a class, are not wealthy, some individual engineers have large means. Engineering foundation seeks to build up its endowment to dimensions worthy of the Profession. Engineers connected with industrial and financial organizations having great resources can aid by convincing proper officials of corporations that the continued prosperity of our industries depends upon continued progress of research. Since the commercial and industrial establishments of the country reap the larger proportions of the financial profits arising from scientific and technological work these establishments should contribute liberally to the support of research.

Scientists are more largely concerned in research in pure

science, the search for undiscovered knowledge for its own sake, the usefulness of which may not become apparent in some instances for many years. Between this most advanced line and the development of specific industrial devices or processes, lies the large field of research in applied science and the industries which especially concerns technologists. In this broad field there is scarcely an item of work in which the engineer in some branch of his practise is not directly concerned. Sooner or later the engineer uses all the results of research in science and the industries.

There are many problems relating to the materials and forces of engineering on which further knowledge is needed. Progress will be made approximately in proportion to the funds made available. But there are other kinds of problems which concern the engineer. No longer may one declare, as did Professor J. B. Johnson, a generation ago, that "Engineering differs from all other learned professions in this, that its learning has to do only with the inanimate world, the world of dead matter and force." Many acute social and economic questions of our day need the dispassionate, impartial, patient study of scientists and technologists. To these questions must now be applied the scientific method of collecting facts by thorough study, and the engineer's capacity for planning and performing, instead of ill-considered "reforms."

Engineering works, public, corporate and private, frequently involve studies of special problems or in themselves constitute full-sized experiments, which could be made to yield important data for general technical use. Sometimes the engineers in charge do not perceive the opportunity, not having been trained in research work. More often the possibilities are realized, but means, men and time are not available because of the urgency for completing the project with a minimum expenditure in the shortest practicable time.

Occasionally experimental work is undertaken in accordance with a well conceived plan as a necessary or desirable adjunct to the main operation. In such cases the exigencies of the main operation sooner or later interrupt the experimental work; or the men who have it in hand leave the force; or the information is gained, but never written up; or the statement is buried in some report of limited circulation; or greater familiarity with research methods and a broader conception of the problem could, with small additional expense, have secured much more valuable results and have made them more generally useful.

Again, many construction or manufacturing operations might be made to yield useful data of greater value than those obtained from small-scale laboratory experiments, if only trained observers with suitable instruments were provided. Often the expense would be slight. Sometimes for lack of trained observers occurrences of scientific significance pass unnoted.

The services described in the foregoing paragraphs, and many others, could be performed by Engineering Foundation, if adequate funds could be placed at its disposal. The Foundation does not plan to build laboratories and conduct research work directly but rather to stimulate coordinate and support research work in existing scientific and industrial laboratories cooperating, insofar as may prove advantageous, with the, National Research Council.

Mr. Charles F. Rand, of 71 Broadway, New York, Past-President of United Engineering Society, and of the American Institute of Mining and Metallurgical Engineers, was elected chairman of Engineering Foundation March 19, to succeed Dr. W. F. M. Goss, resigned. With the collaboration of Mr. Swasey, Mr. Rand is actively seeking additions to the endowment fund which will swell the total to at least a million dollars in the near future. Mr. Swasey's gifts amount to $300,000.

The office of Engineering Foundation is in Engineering Societies Building, 29 West 39th Street, New York. Further information may be had by addressing this office or Chairman. A booklet giving an account of the Engineering Foundation and its work will be mailed upon request.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

COMMITTEE ON COOPERATION WITH AMERICAN INSTITUTE OF ARCHITECTS

The Committee on Cooperation with the American Institute of Architects met in Washington on May 4. A general discussion on the bill for licensing engineers as submitted by the License Committee of Engineering Council was held. The similarity of the functions of engineers and architects was also discussed. It was the unanimous recommendation of the Committee that in their judgment it was desirable for the American Institute of Architects to become members of Engineering Council and that the members of the Committee belonging to the American Institute of Architects submit it to them for their consideration. It was further agreed that cooperation of architects and engineers was desirable in formulating basic laws involving the registration or licensing of architects and engineers.

The afternoon session was devoted to a discussion regarding the design and construction of certain bridges. The Committee also touched upon the subject of unionization of draftsmen, and it was unanimously agreed that Engineering Council should be requested to appoint a Committee to consider the desirability of the unionization of draftsmen and other subordinate employees.

PREPARATION OF LEGAL PAPERS BY ENGINEERS

The New York Court of Appeals recently handed down an opinion which seemed to restrict the drawing of legal documents to persons possessing the right to practise law. This raised question in the minds of some engineers as to whether engineers and architects could continue in New York State to prepare contracts and certain other legal or semi-legal documents as has been their practise hitherto. Such a request was referred by the American Society of Mechanical Engineers to Engineering Council. The letter below contains an answer by an eminent legal authority.

Law Offices of
PARKER & AARON
New York

April 15, 1920

Alfred D. Flinn, Esq., Secretary,
Engineering Council.

We have your inquiry of March 16th calling our attention to the decision recently rendered by the Court of Appeals, Judge Crane writing the opinion. The decision referred to is that of People vs. Alfani, 227 N. Y., p. 334. In that case there was evidence, as the chief Judge said, "consisting of defendant's

sign and repeated acts which permitted the trial court to find that the defendant held himself out to the public as being entitled to and did practise law." Defendant had a sign up advertising himself as a Notary Public and as a person drawing "all legal papers." The evidence showed that he did draw a bill of sale and chattel mortgage and advised as to the necessity of filing the mortgage in the County Clerk's Office and that he charged and received $4.00 therefor. When the client was leaving he inquired of the defendant, "In case I have any trouble of any kind and I need any legal advice, can I come back to you?" to which the defendant replied "Yes."

In People vs. Title Guarantee & Trust Co., 227 N. Y., p. 366, a similar question arose in the prosecution against the Title Guarantee & Trust Company for drawing deeds and similar instruments in connection with their business of insuring titles to real estate, and the court held that such action did not violate the statute. The Court says:

"We know that in cities constantly men engaged in the real estate business and banks have prepared for their customers such instruments without doubt or criticism.

The Legislature when it enacted not only section 280 of the Penal Law, which we have been considering, but also section 270 relating to the practise of law by an individual without being admitted and registered, was charged with the same knowledge of prevailing customs and practises with which we are chargeable. Its members knew, oftentimes doubtless by practical and personal observation and experience, that laymen throughout the state were rendering such services as are here involved. Not only by practise and custom but by inherent privilege they had the right to do this unless forbidden by statute, and if the legislature intended to prohibit a widespread practise and establish a new rule it was its duty to say so clearly and unmistakably in the statute relating to the practise of law and rendition of legal services by individuals. It did not say so and in my opinion there is not to be found in that section of the Penal Law any provision against the rendition of such services by an individual. We think the same idea is emphasized as in section 280 that an individual who is not admitted to practise must not assume the character of an attorney at law. He is forbidden to practise or appear 'as an attorney at law or as an attorney and counselor at law' or to make it a business to practise 'as an attorney at law or an attorney and counselor at law' or to hold himself out to the public as being entitled 'to practise law as aforesaid or in any other manner' or 'to assume to be an attorney or counselor at law'. But there is nothing which can fairly be regarded as indicating an intention to abolish an existing and widespread practise and to prevent a layman as such and without any simulation of or pretense to the character of an attorney from drawing a simple instrument as instructed by his customer and not involving or predicated upon any legal advice then given."

Engineers having special knowledge of the engineering work required and the professional skill enabling them to express it, are not precluded as an incident in the practise of their profession from preparing "contracts for engineering work as has been the common practise for years". By so doing they are not holding themselves out as practising law and are not practising law.

Very truly yours.

(signed) PARKER & AARON.

CURRENT ENGINEERING TOPICS

ARMY REORGANIZATION BILL

The Lenroot Amendment to strike out the section of the Army Reorganization Bill which provides a separate construction service was defeated in the Senate by a vote of 18 to 38. When the House was considering the Army Reorganization Bill it had first voted to maintain the Construction Division as a separate service and later reversed its vote by the very small margin of 168 to 158. This is the most vital thing in the Army Reorganization Bill from the civilian engineer's standpoint; and it is distinctly a compliment to the manner in which civilian engineers handled the construction service during the last emergency.

PROVISIONS OF ENGINEERING INTEREST IN LEGISLATIVE, EXECUTIVE AND JUDICIAL APPROPRIATION BILL

This bill is finally passed by Congress provides $60,000 for enforcing the wireless communication laws; $30,000 is provided for investigation and standardization of methods and instruments employed in radio communication. The work is to be done at the Bureau of Standards.

The sum of $25,000 was provided for the continuation of the present investigations on the production of optical glass; $25,000 is allowed for metallurgical research; $30,000 for testing chemicals, etc., and $10,000 for the development of color standards and color measurements.

The structual materials investigation which has been carried on at the Bureau of Standards is provided with an additional $125,000. This investigation pertains largely to cement. $25,000 was appropriated for investigation of fire resisting properties of building materials and conditions under which they may be most efficiently used.

For the further investigation of standards of practise and methods of measurement of public utilities, such as gas, electric light and power, water, telephone, central station heating, and electric railway service, there was appropriated $85,000.

Forty thousand dollars were authorized to be used in the standardization and testing of gages, screw-threads, and standards required in manufacturing. $15,000 additional is to be used for developments of methods of testing and standardizing machines, motors, tools, measuring instruments, and other apparatus and devices used in mechanical, hydraulic and aeronautic engineering.

CIVILIAN ENGINEERING TRAINING FOR ARMY AIR OFFICERS

Not more than twenty-five officers of the Army are to be detailed to pursue courses of aeronautical engineering at colleges and universities throughout the states that are fitted to give such instruction, according to the provisions of a bill which has just passed the Senate.

The bill authorizes the Secretary of War to detail these officers and to make choice of colleges and universities to which they are to be assigned.

U. S. CHAMBER OF COMMERCE ELECTS DIRECTORS

The Chamber of Commerce, U. S. A., at its annual meeting in Atlantic City, April 26 to 29, elected two engineers as Directors of the Chamber. Mr. Howard Elliott, Member, American Society of Civil Engineers; Chairman Board, Northern Pacific R. R., New York City. Mr. L. B. Stillwell, Past-President, American Institute of Consulting Engineers and of American Society of Electrical Engineers; Member, American Society of Civil Engineers; Consulting Engineer, New York City.

DR. C. O. MAILLOUX ELECTED HONORARY MEMBER OF THE FRENCH SOCIETY OF ELECTRICIANS

Shortly after the election of Dr. C. O. Mailloux (Past President of the A. I. E. E.) to the Presidency of the International Electrotechnical Commission, last October, he was proposed, by Prof. Blondel, and other prominent French electrical men, for honorary membership in the Societe Francaise des Electriciens. Dr. Mailloux had been advised unofficially of this election, but

had not received the official announcement thereof, which came during his absence abroad in a letter from the President of the Society informing him that he had been elected unanimously at a special general meeting held December 22, 1919.

The official *Journal* (Bulletin) of the Society for December, 1919 (No. 84), the publication of which was delayed several months by the printers' strike, and which has only recently arrived here, contains the official announcement of the election. The General Secretary of the Society, in moving the resolution, at the request of the President, recalled "the valued services of all kinds rendered to the cause of France by Dr. Mailloux who, by reason of his election to the Presidency of the International Electrotechnical Commission, was entitled to a place among the Honorary members of the Societe Francais des Electriciens." The vote was unanimous. Dr. Mailloux, while in Europe, received many congratulations upon this new and high honor.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

GRADUATE ENGINEER, for part time work in correspondence courses in Dynamo Electric Machinery. Practical operation experience necessary; power experience preferred to industrial. Teaching experience not required. Location New York City. Z-1291.

INSTRUCTION IN ELECTRICAL ENGINEERING. Duties beginning Sept. 1st, in New England College mainly instruction in Electrical Engineering laboratory. Graduate of one or two years experience desired.

ENGINEER for research and investigation on cable insulations. Must be able to conduct investigation on own initiative and report progress of company. Location Hastings, N. Y. Z-1227.

ELECTRICAL OR MECHANICAL ENGINEERS, technically trained, with selling experience on electrical or power plant installations to go to Columbia or Venezuela. Prefer men who have been through the General Electric Company's test. Age between 25 and 35. Z-1275.

ELECTRICAL ENGINEER experienced in small house lighting systems. Engineer experienced in control apparatus desirable. Location New York City. Z-1248.

GRADUATE ELECTRICAL ENGINEER for mining company in Mexico. Some electrical testing and construction experience essential and must be able to keep the present plant in working order. Spanish desirable but not essential. Location Mexico. Z-1249.

ELECTRICAL ENGINEER familiar with the theory and design of Chadburn, Cory, Evershed Ford, Sperry and Vickers systems of fire control instruments and ability to make necessary adjustments and check accuracy of completed installation also to give instructions as to care and use of such apparatus. For further information see U. S. Civil Service or book on file in this office. Z-1254.

ILLUMINATING ENGINEER to prepare correspondence course in Electric Lighting and also to correct papers. Teaching experience desirable, but the ability to explain in writing is essential. Must be located near New York City. Z-1235.

ASSISTANT ENGINEER in general municipal practise, but particularly waterworks, electric light and sewer construction. Prefer man between the ages of 28 and 35 possessing good health, good address, and a reasonably pleasing personality. He must be of unquestioned integrity and veracity, energetic and competent. Location Tennessee. Z-1259.

RESIDENT ENGINEERS for general municipal practise, but particulary water works, electric light and sewer construction. Prefer man between the ages of 28-35 possessing good health, good address, and a reasonably pleasing personality. He must be of unquestioned integrity and veracity, energetic and competent. Location Tennessee. Z-1240.

GRADUATE MECHANICAL AND ELECTRICAL ENGINEER experience in car shop work. Competent to keep in first class condition of maintenance sub-surface-contract, electric, street railway cars, and to develop a repair shop for that work, selecting and placing the proper tools and take charge of such operations when effected. Location New York City. Z-1211.

INSTRUCTOR for technical school in electrical laboratory and class room work. Duties will include responsibility for an elementary electrical course, and assistance in a more advanced course. Must be engineering school graduate with few years practical experience. Previous teaching experience desirable. Apply by letter stating age, education and experience and enclose recent photograph if available. Location Brooklyn, New York. Z-1214.

GRADUATE ELECTRICAL ENGINEER experienced in electrical machinery for export office. Spanish desirable. Location New York City. Z-1175.

ELECTRICAL AND MECHANICAL ENGINEER for 3000 H. P. hydro electric plant in Bolivia. Must be able to improve, efficient and take charge of plant. Z-1150.

HEATING AND VENTILATION DRAFTSMAN in connection with construction work. Position involves board work on heating and ventilating systems exclusively. We prefer a graduate engineer who has had three or four years of practical experience in this work. Salary is not fixed but is commensurate with the man's ability. Permanent position with excellent opportunity for advancement. Location Ohio. Z-1133.

YOUNG ELECTRICAL DRAFTSMAN for illumination work. A man who has had two years technical training and who is able and willing to do drafting may be able to fill our requirements in this case. Permanent position with excellent opportunities for advancement. Location Ohio. Z-1134.

DRAFTSMAN to lay out wiring for lighting and power work for various types of buildings. Must have had experience with some electrical contractors. State experience, age and salary desired. Location New York City. Z-1138.

ELECTRICAL ENGINEER for drafting and layout work also work in field. This is for railroad company in New York City. Z-1142.

YOUNG MAN for engineering research and manufacturing departments of concern making grafonolas, records and dictaphone. Technical education essential with from one to eight years experience. Only men of caliber and ability considered. Location Connecticut. Z-1121.

ELECTRICAL ENGINEER for research work on obtaining Helium from natural gas, also draftsman for same work. Location Texas. Z-1125.

INSTRUCTORS. An examination will be held in Sampson Hall U. S. Naval Academy, Annapolis, Maryland, beginning at 9:00 a. m. Tuesday, June 15, 1920, for the selection of five instructors in the Department of Electrical Engineering and Physics. A bill now before Congress increases these salaries about 30%. Candidates must demonstrate a thorough knowledge of one of the subjects of Physics, Chemistry or Electrical engineering, and a sufficient grounding in the others to enable them to teach if necessary. Blank forms forwarded on request. Location Maryland. Z-1064.

TRAFFIC ENGINEERS for fruit cargo vessels. Technical training essential and practical experience and some knowledge of refrigeration fans, motors, etc., required. Work will be on board steamers which carry refrigerated banana cargoes and possibly some time spent in port occasionally. Regular schedule of boats gives about five days in New York each four weeks. Work will consist of investigation of transportation problems and supervision of care of fruit, etc., and should be pleasant as most of boats are large, well fitted carry good class of passengers. Z-1112.

EXECUTIVE ENGINEER to erect and operate an electric plant for the manufacture of ferro-vanadium. Actual experience of one of the existing plants now making this product essential. Must be entirely familiar with the technique of the electric process and be able to tell whether an ore is suitable for such process. Location either New Jersey or Colorado. Z-1117.

ELECTRICAL ENGINEER (A) with 3 or more years teaching experience desiring to make changes to electrical machine design work wanted to take up interesting line of alternating current development. Splendid opportunity for man of ability and energy to make permanent connection. ENGINEER (B) with technical training, experienced in design of alternating current motors to take up development of adjustable and varying speed alternating current equipment. Permanent position with good opportunities for growth. TECHNICALLY TRAINED ENGINEER (C) with railway operating experience, desiring to make change to design work, wanted for development work connected with railway electrification. Permanent position for man of ability. Z-1093 A-B-C.

ASSISTANT SUPERINTENDENT OF ELECTRICAL DEPARTMENT. Technical graduate with some experience in electrical construction works. Duties would consist of drafting, office work and outside construction supervision. Must also be able to assist in systematizing department employing about 30 men. Z-1079.

LUBRICATION ENGINEER for the Philippines; must be able to speak Spanish fluently and must be experienced as there is no time for instruction. Salary $3000 and traveling expenses. Location, Philippines. Z-901.

LABORATORY INSTRUCTOR IN ELECTRICAL ENGINEERING at a midwestern State College. Position open September 1st 1920. Z-1292.

MEN AVAILABLE

ELECTRICAL ENGINEER, technical education with 16 years experience in installations of all standard power house and substation equipments up to 110,000 volts. Have also electric furnace operation experience and maintenance of power house and substation equipment rebuilding of generators and transformers. Married, 36 years, salary depends on location. E-2199.

TELEGRAPH ENGINEER, small electrical apparatus all kinds. Twenty years experience including four years abroad. Sales and foreign trade understood, also foreign telegraph systems. Desire position anywhere abroad on salary, or will accept commission if good proposition. E-2200.

RAILWAY ENGINEER, technical graduate, eight years of vigorous experience in this branch with large manufacturing company. Steam road electrification work preferred although will consider any engineering work pertaining to electric traction. Married Age 32. E-2201.

EXECUTIVE, GRADUATE ELECTRICAL ENGINEER of broad mechanical and electrical experience with well known corporations, in production and design of electrical applicances, and in the steel and elevator industries. Factory manager familiar with modern production methods. Now engineer executive with large company. Location New York. Salary $6000. E-2202.

ELECTRICAL ENGINEER with twenty years varied experience in electrical field, viz. construction, estimating, contracting, jobbers salesman etc. including several years as teacher of electrical applications in a nationally known vocational school. Will consider position in any of the general lines indicated above. Last years salary bonus and commissions over $5000. E-2203.

ELECTRICAL MECHANICAL ENGINEER, Age 33, Three and half years technical training, nine years practical engineering experience, in design, construction, operation and maintenance of large electric powerplants, high tension systems, transformer, switching and rotary converter sub-stations, familiar with sugar house electrification and industrial plant installations, efficient with large steam turbine, reciprocating engine and internal combustion engine driven power plants, erection and installations of boilers and condensing systems. Good organizer, speaks Spanish fluently. Familiar with all kinds of Labor found in Latin Americas. Salary $5000 per year to start, traveling expenses, will go to any part of the world. Available after May 15th, Address Engineer, Apartado 2593, Havana, Cuba. E-2204

ELECTRICAL ENGINEER; age 27, married, technical graduate Three years teaching experience in electrical engineering, one year in Physics. Now in latter position. Considerable knowledge of radio. Desires position in teaching or commercial work. Available June 15th. E-2205.

GRADUATE ELECTRICAL ENGINEER B. S. Degree, wishes position as Assistant to engineer. Have had a varied experienced in testing and maintenance electrical machinery and equipment. Location preferably in east, but not essential. Minimum Salary 1800. E-2206.

GRADUATE ELECTRICAL ENGINEER (1911) married, age 31, desires position of greater responsibility in consulting and sales work. Has had factory and office experience also erection repair and executive experience with Westinghouse and General Electric. Capable of handling construction erection work also sales engineer. Location middle west. Salary $3300. Available soon. E-2207.

INDUSTRIAL ENGINEER, technical graduate, Assoc. Member A. I. E. E. Assoc. Member A. S. C. E. Twelve years practical experience, surveys, designs, and construction supervision, millbuildings and equipment, structural steel, reinforced concrete designs and details, plant inventory, valuations, and inspection of construction materials, recently established in private practice at 50 Bromfield street, Boston Mass. Engineering service available on hourly basis. E-2208.

MECHANICAL & ELECTRICAL ENGINEER, college graduate, twenty years varied experiences, electrical mechanical, steam and selling, public service lighting and power, telephone and industrial companies in field and office, design, construction, maintenance, operation; good manager. Age 45; Available on reasonable notice. E-2209.

ELECTRICAL AND HYDRAULIC ENGINEER, twenty years experience as executive in design, construction, maintenance, and operation of large hydroelectric plant of 200,000 h. p. capacity. Experience includes heavy overhead and underground transmission and distribution systems. Has had much experience in power measurement and in preparing power contracts. Is ready to undertake general supervision of electrical development work of any size or act as technical adviser to investment syndicate. Reason for seeking new connection: merger. E-2210.

RESEARCH ENGINEER, graduate E. E. experienced in research and development of electrical appliances thoroughly familiar with patents and patent law, about to be registered as patent attorney, can handle laboratory of small concern, or assist in management of large one, available 30 days. Salary $2000. E-2211.

ELECTRICAL ENGINEER; age 30; 1916 Univ. graduate; 2 years Westinghouse test, trouble, and construction work. Considerable construction and layout experience before and after University work. Experienced teacher. Desires position as electrical engineer in power, electric railway or industrial service. Location preferred. Middle West. E-2212.

ELECTRICAL SUPERINTENDENT, graduate E. E., seven years industrial engineering, maintenance and construction; four years experience in manufacture and testing of wires and cables, desires to connect with a concern who can appreciate results. Correspondence and interviews solicited. H. Murray, 29 Gage Ave. So. Hamilton. Ontario, Canada. E-2213.

ELECTRICAL CONSTRUCTION ENGINEER or Chief Electrician for large plant. Seven years experience in installations of electrical machinery, repairs and design. Technical and Practical education. Age 25, Location anywhere. Available June 15. E-2214.

ELECTRICAL ENGINEER, thirty three, technical graduate, fourteen years electrical and mechanical design and construction; experienced in industrial plants, power houses and substation desires position of responsibility, with consulting or contracting engineers. Salary $3600. E-2215.

Electrical and Mechanical 18 years practical training technical education several years in charge of men, good on production and systematic. Wishes position as Superintendent of electrical department Works Engineer or Safety Engineer. What have you. Age 34, Married. Salary $2700. E-2216.

Plant or Works Engineer for large concerns to assume supervision of mechanics, draftsmen, electricians and general plant maintenance and construction, also generation and distribution of power heat and air. E-2217.

Power Sales Engineer—Graduate electrical engineer with five years experience in industrial power work, both with industrial concerns and public utilities. Desires permanent connection with an aggressive new business department of a public utility. E-2218.

Stenographers and Typists experienced, for part time work, afternoons, evenings, or Saturday all day. Work done at at home also. 40 Irving Place. Telephone Stuyvesant 5524.

Engineer, experienced in steam electric power and electric railway work; expert research man, especially in combustion and other technical investigations. Age 40, married, E.E. and M. S. Salary asked $4000. Permanent Position desired. E-2219.

Technical Electrical Graduate, Age 30, Married; 4 years power experience, desires a position with an Electrical establishment where there are good opportunities for advancement in the engineering field. Available on 30 days notice. E-2220.

Electrical Engineering Graduate, 1919; B.S. Age 23, Single desires position in engineering department of concern manufacturing electrical machinery or power supply company. Two years testing experience on D. C. Machinery. Salary $1500. E-2221.

Associate Professorship in Electrical and Telephone Engineering desired. Technical graduate, M. E. Six years combined teaching and consulting experience. Three years in Plant and Engineering Departments of Bell Telephone Company; two years in Electrical Distribution and Power Plant work; one and a half years training in Research work; will consider commercial position also. E-2222.

Foreman of Construction, 18 years experience in line construction of all classes conduit cable and motor installations, meters, etc. Married, 35 years old. E-2223.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal authorities, is given below, together with the addresses as they now appear, on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Arthur J. Hall, 634 East End Avenue, Pittsburgh, Pa.
2.—Lincoln Nissley, 1213 Pioneer Bldg., St. Paul, Minn.
3.—Lieut. W. J. Strieby, 34 Simpson Road, Ardmore, Pa.
4.—Charles P. Wood, Metuchen, N. J.

PERSONAL

Ludwig Hommel will continue to be in charge of the Pittsburgh office of the Wagner Electric Manufacturing Company, which has been moved to 530–534 Fernando Street.

Frederick G. Cottrell, Chief Metallurgist, Bureau of Mines, was nominated May 5 by President Wilson to be Director of Bureau, succeeding Dr. Van H. Manning, whose resignation will take effect June 1.

J. G. Carroll, chairman of the Pittsburg Section of the Institute, has left the service of the Westinghouse Electric & Manufacturing Company, at East Pittsburgh, and on May 1 became chief engineer of the Walker Vehicle Company, Chicago.

C. B. Daniels, Secretary of the Colorado Society of Engineers, announces the opening of a new office in the Cooper Building, Denver, Colo. Attention is invited to the free engineering employment service in cooperation with the U. S. Government free employment bureau, the Engineering Societies employment bureau, the Colorado free employment office, and other technical and welfare organizations.

Walter A. Hall, chairman of the Sections Committee of the Institute, has left the service of the General Electric Company, at West Lynn, and on April 15 became Vice-president and general manager of the Murray & Tregurtha Corporation, Atlantic, Mass., manufacturers of marine engines. This company, originating in 1889, has recently reorganized and is extending its activity in both marine and commercial fields.

W. S. Finlay, Jr., has resigned as Superintendent of Motive Power of the Interborough Rapid Transit Company to accept the position of a vice-president of the American Water Works & Electric Company. Mr. Finlay's early work in the I. R. T. Co. was identified with the construction of the 59th Street Power Station. In 1909 he left the Company, but returned in 1915 to take charge of the installation of turbines and auxiliary mechanical equipment necessitated by the extensions to the subway and elevated systems; and upon the death of Mr. H. G. Stott was appointed his successor as Superintendent of Motive Power.

Mr. Ira Cushing, formerly consulting engineer with The General Electric Company, has taken a position as electrical engineering salesman with Mr. James C. Barr, Manufacturers' Agent, 84 State St., Boston, Mass. specializing in the products of the Electrical Engineers Equipment Company of Chicago. and the Locke Insulator Corporation of Victor, N. Y., for which Mr. Barr is district representative in New England. Mr. Cushing entered the employ of The General Electric Company at Schenectady in December, 1901, and in 1906 he was transferred to the Boston Office of the company. He served for several years as Secretary-Treasurer of the Boston Section of the A. I. E. E. and in 1918 he was elected Chairman of the Section.

OBITUARY

John Bogart, civil engineer, died of pneumonia on April 26, 1920, at his home, 640 Madison Ave., New York, after an illness of eleven days. Mr. Bogart, a descendent of a Dutch family which settled in Albany in 1639, was associated during his early career with the development of Central Park. During the Civil War he worked on the fortification of Fort Monroe and other points. Subsequently he became chief engineer of the Park Department of New York, New York State engineer, constructing engineer of the Washington Bridge, New York, and chief engineer of the Rapid Transit Commission. Mr. Bogart was one of the foster fathers of the Institute, as it was during his term as secretary of the A. S. C. E. back in the pioneer days of Institute history, 1885 to 1887, that the Institute was granted permission to use the rooms of the A. S. C. E. on Twenty-third Street as a meeting place and home.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (APRIL 1-30, 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

AIRCRAFT YEAR BOOK

Issued by Manufacturers Aircraft Association, Inc. 1920. Publ. by Doubleday, Page and Company, N. Y., illus., cloth, 9 x 6, 333 pp. $2.

The first issue of this annual review of the industry appeared in 1919. The present issue, the second of the series, reviews the progress up to date in various fields of aeronautical activity. Aircraft in commerce and in warfare, technical developments between 1914 and 1919, and cross country flying are discussed, and a detailed story of the recent achievements of the firms composing the Association is given. The book also contains the text of the convention relating to international air navigation, the report of the American Aviation Commission, a chronology of the events of 1919 and appendices giving information on governmental activities.

THE ALDRICH MARINE COMPANY.

N. Y., Aldrich Publishing Co., 1920. 246 pp., 8 x 4 in., flexible cloth, $5.

The third edition of this useful directory contains the list of concerns which build and repair vessels in the United States, and also of steamship, steamboat and other vessel owners operating ships under the American flag. The lists are divided geographically, the main sections covering the Atlantic Coast, the Pacific Coast, the Great Lakes and the Mississippi Valley. The shipbuilders' list comprises over 400 shipbuilding or repair yards and about 400 drydocks and marine railways. Particulars of Government-owned or controlled ships are not included. The volume is thoroughly indexed.

COURS DE MECANIQUE RATIONNELLE avec de Nombreuses Applications al'Usage des Ingénieurs—Cinématique—Statique—Dynamique.

By L. Legrand. 1920, Paris and Liége, ch. Beranger, 364 figures, 618 pp., cloth, 10 x 6 in., 48 fr.

The author of this textbook believes that there is need for a work which will present the subject in strictly scientific manner, but which will draw its illustrations from the realm of industrial mechanics, rather than from celestial mechanics, as is usually done in theoretical treatises, and presents the present book for this purpose. He has attempted to supply a complete course in which an engineer will find the theory illustrated by problems which arise in the practise of applied mechanics in various industries.

ECONOMIC DEMOCRACY.

By C. H. Douglas. N. Y., Harcourt, Brace and Howe, 1920, 5 x 8, 140 pp., cloth, $1.60.

This book, based on the cost of investigations of the author while assistant superintendent of the Royal Aircraft Factory of England, and written for the most part under the pressure of war conditions, is an attempt to disentangle from a mass of superficial features such as profiteering and alleged scarcity of commodities, a sufficient portion of the skeleton of the structure we call Society as will serve to suggest sound reasons for the decay with which it is now attacked, and afterwards to indicate the probable direction of sound and vital reconstruction. Democracy, the author believes to be not so much a matter of elective administration as of distributed economic power, the attainment of which is a question of the establishment of the just price and the control of the policy of industry through the mechanism of the credit system.

ELEMENTS OF STEAM AND GAS POWER ENGINEERING.

By Andrew A. Potter and James P. Calderwood. 1st edit. N. Y. and Lond., McGraw-Hill Book Company, 1920, 8 x 5, cloth, 297 pp., illus. $2.50.

The object of this treatise is to provide a clear, concrete statement of the principles underlying the construction and operation of steam and gas power equipment, suited to familiarize students of engineering with power plant equipment before they take up the study of thermodynamics and design, and to those responsible for the operation of power plants.

GEOLOGY OF THE MID-CONTINENT OILFIELDS.

By T. O. Bosworth. N. Y., The Macmillan Co., 1920. 314 pp. illus., plates, charts, maps, 9 x 6 in., cloth, $3.

Contents: Introduction and Bibliography. Geographical and Geological Situation of the Mid Continent Oil Region. History of the Development of the Mid Continent Oil Region. Geological Structure of the Mid Continent Oilfield Region. Geological History of the Oil Bearing Deposits. Stratigraphy and the Oilfields. The Oil Accumulations and their Relation to Geological Structure. Character of the Oil. The Natural Gas. Production of Gasoline from Natural Gas. Salinity of Oilfield Waters. Some General Conclusions.

The present interest in the search for oil makes this book on the greatest of the world's developed oil territories particularly timely. The fields included in this region have not heretofore been regularly grouped together as a whole in oil literature but have been scattered under different titles according to location. The author has endeavored to deal with the Mid Continent Oil Region as a well defined unit with a natural geological boundary, and to that end has set forth and reviewed the facts which he has drawn from many sources, especially the United States and the State Geological Surveys.

HANDBOOK OF ORE DRESSING—Equipment and Practise.

By A. W. Allen. 1st edit., N. Y. and Lond., McGraw-Hill Book Co., 1920. 166 fig. and tables, 240 pp., flexible cloth, 7 x 5 in., $3.

This is an attempt to supply a handy, practical vade-mecum for millmen and engineers which will cover the various stages in the mechanical handling and preparation of an ore for metallurgical treatment. The volume includes a brief bibliography and is of convenient size for the pocket.

HOW TO MAKE AND USE GRAPHIC CHARTS.

By Allan C. Haskell, with an introduction by Richard T. Dana. 1st edit., N. Y., Codex Book Co., 1919. 540 pp., diagrams, 6 x 9, cloth, $5.

The object of this book is to call attention to the many functions which graphic methods can accomplish and to indicate the suitability of the various methods of charting for various purposes. After describing the theory and construction of the various types of charts, the author gives many examples of charts used to aid in organization and management, in analyzing costs and operating characteristics, in recording tests, in predicting trends and tendencies, in computing, designing and estimating. Bibliographies are given with most of the chapters.

OPPORTUNITIES IN ENGINEERING.

By Charles M. Horton. N. Y. and Lond., Harper and Brothers. 90pp., 8 x 5 in., paper. $1.

The tremendous power which engineers wield in world affairs has inspired the author to set forth in this book the opportunities for constructive work which lie before the men who selects engineering as his profession. He also describes the type which, being best fitted for the work, is most likely to succeed and gives some hints for the guidance of the student who is choosing his vocation, as well as some examples of what has been done by those already in the work.

PROSPECTOR'S FIELD-BOOK AND GUIDE.

In the Search for and the Easy Determination of Ores and Other Useful Minerals. By H. S. Osborn. 9th edition thoroughly revised and enlarged by M. W. von Bernewitz. N. Y., Henry Carey Baird & Co., Inc., 1920. 364 pp., illus., tables, 7 x 5 in., flexible cloth, $3.

Since 1910, when the eighth edition of the Guide was published, conditions and methods in the mining field have changed, necessitating the addition of much new material in order to bring the work up to date. Lists of suitable outfits, new field tests, notes on sampling, an explanation of the unit system of selling ores and an entirely new chapter on the alloy minerals are included in this revision, and the principal characteristics of certain ore deposits in various parts of the world are discussed. The book also contains a glossary of mining and mineralogical terms and an appendix of useful tables.

RETAINING WALLS. Their design and Construction.

By George Paaswell. 1st edit. N. Y., and Lond., McGraw-Hill Book Co., 1920, diagrams and illus., 275 pp., 9 x 6, cloth, $4.

This work differs from the usual treatise on the subject by being essentially a text on the design and construction of retaining walls, rather than an analytic study of the action of the retained earth masses. The failures of the walls are usually not due to weaknesses in the theory of pressures, but to faulty design and construction, in the author's opinion, and it is to these questions he directs his attention.

TRANSIENT ELECTRIC PHENOMENA AND OSCILLATIONS, THEORY AND CALCULATION OF.

By Charles Proteus Steinmetz. 3rd edit., revised and enlarged, N. Y. and Lond., McGraw-Hill Book Company, Inc., 1920. 9 x 6, cloth, 696 pp. $6.

This volume, which is to some extent a continuation of the author's Theory and Calculation of Alternating Current Phenomena, deals with the transient phenomena of the readjustment of stored electrical energy which is necessitated by a change in circuit conditions. The present edition has undergone extensive revision and expansion, and has practically been rewritten. A new section, entitled "Variation of circuit constants", has been added. The method of symbolic representation has been changed from the time diagram to the crank diagram.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Boston.—May 4, 1920, Engineers Club. Report from different committees and election of officers as follows: Chairman, W. I. Middleton; Vice-Chairman, L. W. Abbott; Secretary-Treasurer, Ira Cushing. Subject: "Notes on Electric Power Conditions in New England and on the Pacific Coast During the War." Speaker: George F. Sever. Attendance 60.

Chicago.—April 26, 1920, Auditorium, Western Society of Engineers. Paper: "The Principle of Electric Precipitation and Its Application to Cement Kiln Gases." Speaker: Mr. John H. Lendi, Electrical Engineer of the Universal Portland Cement Company. The talk was illustrated with lantern slides which showed the latest development of the process as applied to cement plants. Attendance 103.

Cleveland.—April 20, 1920, Hotel Statler. Subject: "The Sperry Gyroscope". Speaker: Mr. Robert B. Lea, Engineer Marine Department, The Sperry Gyroscope Company, Brooklyn, N. Y. Attendance 162.

Denver.—April 24, 1920, Kenmark Hotel. Joint meeting of the Colorado Scientific Society, Denver Section A.I.E.E., and the Teknik Club of Denver. Paper: "Radio Telephony." Speaker: Mr. Harry R. Kylie, U. S. Forest Service. The paper was illustrated by diagrams and radio telephone apparatus. Attendance 95.

Indianapolis-Lafayette.—April 16, 1920, Chamber of Commerce. Subject: "Central Station Rates as Affected by Load Factor and Power Factor." Speaker: Professor C. Francis Harding, Purdue University. Attendance 55.

Ithaca.—April 12, 1920, Sibley Auditorium, Cornell University. Joint meeting with Cornell Branch A. S. M. E. Subject: "Industrial Relations." Speaker: Mr. C. F. Hirshfeld, Chief of Research Department, Detroit Edison Co. A social hour was held after the meeting. Attendance 500.

April 23, 1920, Franklin Hall, Cornell University. Subject: "High Tension Insulators." Speaker: Mr. A. O. Austin, Chief Engineer, Ohio Insulator Co. Attendance 40.

Madison.—May 5, 1920, Engineering Building, University of Wisconsin. Subject: "Abstractive and Selective Properties of Radio Circuits." Speaker: Professor Edward Bennett, University of Wisconsin. Professor Bennett gave a brief discussion of some of the requirements of radio circuits to obtain least interference, and to obtain the greatest amount of power from the particular sending station one wished to listen in on. Attendance 25.

Philadelphia.—May 10, 1920 Engineers' Club. A dinner preceded the meeting. Subject: "Professional and Financial Aspect of Electrical Engineering." Speakers: C. W. Plass "Financial Possibilities of the Electrical Engineer," A. W. Hastings and J. W. Anderson "A Comparison of Engineering with other Professions;" F. G. Macarow "Americanization in Industry;" W. H. J. McIntyre "The Value of an Apprenticeship Course to the Apprentice and to the Employer." Attendance at meeting 126.

Pittsfield.—April 15, 1920, Park Club. Subject: "Theory of Vacuum Tubes." Speaker: Professor J. H. Morecroft, New York, N. Y. Attendance 105.

May 7, 1920, Park Club. Subject: "Motor Application in the Large Steel Industries." Speaker: Mr. M. A. Whiting, General Electric Company, Schenectady, N. Y. Attendance 36.

Portland.—April 13, 1920, University Club. Subject: "Preliminary Reconnaissance of the Skagit River Power Project

of the city of Seattle." Speaker: Mr. C. F. Uhden, Attendance 60.

St. Louis.—April 28, 1920, Union Electric Assembly. This was a social meeting, opened with the presentation of the five reel picture "The Cody Trail" and followed by another film "Through the Canadian Rockies." Dancing followed the showing of the pictures, and a buffet luncheon was served. Attendance 160.

Schenectady.—April 16, 1920, Edison Club Hall. Subject: "The Transmission of Telephone Currents." Speaker: Mr. O. B. Blackwell, A. T. & T. Co., New York. Mr. Blackwell illustrated his talk by means of lantern slides. Attendance 120.

April 21, 1920, Edison Club Hall. Subject: "Self-Interest in Electrical Development." Speaker: Mr. A. Emory Wishon, President of the Pacific Coast Section of the N. E. L. A. Attendance 73.

Seattle.—April 20, 1920, Arctic Club Assembly. Business meeting followed by presentation of three papers by men from the Seattle Municipal Light and Power System as follows: Mr. F. R. Nicholas "New Features of the Cedar Falls Pipe Line;" Mr. W. J. McKeen "New Features of Power House Design;" Mr. Glen H. Smith "A New Plan of Distribution" which has been adopted by the department. All the papers were illustrated with lantern slides. Attendance 95.

Toronto.—April 9, 1920, Engineers' Club. Paper: "Protection of Power Circuits under Short-Circuit Conditions." Speaker Mr. I. W. Gross. Attendance 87.

April 23, 1920, Engineers' Club. Annual Meeting. Annual report of the Chairman was read and adopted. Election of officers as follows: Chairman, Frank R. Ewart; Secretary, Perry A. Borden; Executive, O. V. Anderson, L. B. Chubbuck, W. P. Dobson, S. E. M. Henderson, Geo. D. Leacock and Walter F. Wright. The meeting was followed by an informal dinner to President Calvert Townley. Attendance 47.

Washington.—April 13, 1920, Cosmos Club. Illustrated address on "Design of a Super-power Station" by Mr. Harold Goodwin, Jr. Attendance 105.

May 11, 1920, Cosmos Club. Election of officers as follows: Chairman, Milton M. Flanders; Secretary, Ernest T. Walker. After the business meeting a moving picture was shown "Electrification of the Butte, Anaconda and Pacific Railroad." Attendance 40.

PAST BRANCH MEETINGS

University of Arkansas.—April 13, 1920, Engineering Hall. Subjects: "Daylight Saving" by Jack Thompson; "Carbon Arcs for Searchlights" by George Moore; "Effect of Ranges on Distribution Layouts" by Loy Barton; "Current Events" by Max Ware. Attendance 21.

Armour Institute of Technology.—April 20, 1920, Armour Lecture Room. Illustrated lecture accompanied by lantern slides. Subject: "Electricity the Wonder Worker" by Chairman Seyferlich and Secretary Stevers. Attendance 36.

Brooklyn Polytechnic Institute.—April 16, 1920, Potts Lecture Room. Students Paper by Mr. T. M. Feder (class 1920) on "Principles of Design of H. T. Insulators." Also Mr. Elmer J. Goodale, of the New York and Queens Electric Light & Power Co., on "Protective Relays, Design and Application." Attendance 25.

April 30, 1920, Potts Lecture Room. Subject: "Vacuum Tubes". Speaker: Mr. H. J. Van der Bijl, Research Physicist, Western Electric Co. Refreshments were served after the meeting. Attendance 58.

Carnegie Institute of Technology.—April 29, 1920, Machinery Hall. Paper: "The Development of Electric Controllers." Speaker: Mr. H. D. James, Control Division, W. E. & M. Co. The paper was illustrated with a large number of slides. Attendance 40.

University of Cincinnati.—April 20, 1920, Assembly Room. Business meeting. Attendance 66.

April 27, 1920, Assembly Room. Two student papers were presented as follows: "Some Control Circuits as Used at the American Rolling Mill Co.," by Paul H. Felton '20, and "An Electrical Method of Determining the Amount of River Water in Turbine Condensate at the Union Gas & Elec. Co." by T. R. Watts '22. Attendance 69.

May 4, 1920, Engineering Building. Subject: "Some Special Slide Rules gotten up for Valuation Work on the B. & O. R. R." Speaker: Mr. C. S. Meyer. Attendance 75.

May 11, 1920, Engineering Building. Subject: "Results of Tests on a Four Wheel Driven Tractor." Speaker: Mr. A. A. Van Pelt. Attendance 67.

Clarkson College of Technology.—April 26, 1920, Clarkson Chapel. Films were shown on Electrification of Railroads, followed by general discussion. Attendance 78.

Clemson Agricultural College.—April 6, 1920, E. E. Lecture Room. Subject: "Railway Signal Systems." Discussions by Messrs. Cullum and Bunch; "Life of Lamme" by A. G. Gower. "Current Events" by C. O. Durant. Attendance 49.

April 20, 1920 E. E. Lecture Room. Subject: "Rectification of Alternating Currents" by W. D. Banks and Professor S. R. Rhodes; "Lightning" by L. H. Childs; "Current Events" by W. W. Fowler. Attendance 33.

Drexel Institute.—April 29, 1920. Business meeting, followed by paper on "Voltage and Current Regulation on Automobile Generators" by Mr. C. E. Rorda, of Drexel Institute. Attendance 16.

Georgia School of Technology.—April 15, 1920, Physic Lecture Hall. Paper: "Lightning Arresters." Speaker: C. E. Bennett, of the Georgia Railway and Power Company. The paper was illustrated with slides and demonstrated by means of a miniature transmission line. Attendance 55.

May 13, 1920, Y. M. C. A. Auditorium. Subject: "The Hydroelectric Development at Tallulah Falls." Speaker: Mr. C. G. Adsit, of the Georgia Railway & Power Company. Slides and moving pictures were shown of the dams and reservoirs at Burton, Mathis, and Tallulah Falls. Attendance 110.

University of Maine.—April 6, 1920, Lord Hall. Business meeting. Attendance 28.

Michigan Agricultural College.—April 15, 1920. Paper: "Changing Insulators on Live and Dead High-Tension Lines." Speaker: Mr. H. J. Burton, of the Consumers Power Company. Attendance 43.

School of Engineering of Milwaukee.—April 23, 1920. Subject: "Elevator Controls." Speaker: Mr. Harrison P. Reed, Cutler Hammer Mfg. Co. Attendance 70.

North Carolina State College.—March 2, 1920, E. E. Class-Room. Professor McIntyre, of the Electrical Department, gave an interesting talk on the telephone organizations; Mr. E. P. Holmes of the H. L. Doherty Co., and an alumnus of the college, gave a talk on his work since he left school. Attendance 29.

March 9, 1920, E. E. Class-Room. Business meeting regarding electrical show. Attendance 27.

March 16, 1920, E. E. Class-Room. The program consisted of several extemporaneous speeches by various members of the class on humorous subjects. Attendance 23.

March 23, 1920, E. E. Class-Room. Meeting devoted to discussion and work on the electrical show. Attendance 20.

March 30, 1920, E. E. Class-Room. Meeting devoted to discussion and work on the electrical show, the date of which was set for April 10 and 12. Attendance 20.

April 10 and 12, 1920. Electrical show held by the Branch at Winston Hall. The show consisted mainly of exhibitions, demonstrations and stunts with the machinery and apparatus of the extensive laboratory of the electrical department. The attendance for both nights was large.

April 20, 1920, E. E. Class-Room. Business meeting and election of officers: President, D. A. Floyd; Vice President, E. E. Inscoe; Secretary-Treasurer, H. W. Allsbrook. Attendance 21.

University of Notre Dame.—March 14, 1920, Engineering Hall. Paper: "Engineering as a Profession." Speaker: W. J. Douglass. Attendance 22.

March 29, 1920 Engineering Hall. Following papers presented: "The Engineer as a Citizen" by J. G. Malone; "Report on Thesis" by R. G. Arends; "Outline of the Students Course at the Fort Wayne Branch of the General Electric Co." by W. J. Hockett, of the G. E. Co. Attendance 24.

April 23, 1920, Engineering Hall. Paper: "Essentials of Successful Engineering." Speaker: Mr. J. E. Kearns, of the G. E. Co. of Chicago. Attendance 35.

Ohio Northern University.—March 23, 1920, Lehr Auditorium. The following motion pictures were shown: "Telephone Inventors of today" and "Indies the Big Fence." Attendance 232.

April 14, 1920, Dukes Memorial. Subjects: "Electric Vehicles" by Paul Rice, and "An Auto-transformer Installation at Trenton, N. J." by F. Veverka. Attendance 22.

April 21, 1920. Dukes Memorial. Subjects: "Some New Applications of Electricity" by E. A. Erdman, and "Water Power" by D. M. Bockenek. Attendance 16.

April 28, 1920, Dukes Memorial. Subjects: "Steam vs. Electric Locomotives" by Professor J. A. Needy; "The Manufacture of China Ware" was discussed by Mr. Edward Salt. Attendance 27.

May 12, 1920, Dukes Memorial. The purpose of the meeting was to nominate candidates for the Branch officers for the coming year. Attendance 32.

May 13, 1920, K. of P. Hall. Election of officers as follows: Chairman, E. A. Erdman; Vice-Chairman, Paul Rice; Secretary, John W. Ulrey; Treasurer, F. Veverks. Following the election of officers the following program was given in an informal manner: Boxing and Wrestling Matches; Talks by members of the faculty present, smokes and eats; remarks by members of the senior class present. Attendance 48.

Ohio State University.—March 28, 1920. Business meeting. Attendance 37.

University of Oklahoma.—May 6, 1920, Engineering Building. Subject: "The Design and Construction of Transformers." Speaker: Professor E. R. Page. Attendance 29.

Oregon State Agricultural College.—April 15, 1920. Subject: "Power Rates and Distribution." Speaker: Mr. F. E. McKenna, of the Mountain States Power Company. After the speaker had finished the following motion pictures were shown: "King of the Rails" and the "Butte Anaconda and Pacific Railroad." Attendance 68.

April 28, 1920. Subject: "Testing a Hydroelectric Plant" Speaker: Mr. W. D. Proebstel, of the Portland Railway Light and Power Company. Attendance 110.

University of Pennsylvania.—May 3, 1920, Engineering Building. Election of officers as follows: Chairman, J. F. Haines; Vice-Chairman, Heidelbaugh; Secretary, N. R. Guilbert; Treasurer, Gallagher. Subject of the meeting: "The Development of the Storage Battery." Speaker: J. Jones. Attendance 21.

University of Pittsburgh.—April 13, 1920. Paper: "Electric Furnaces in the Steel Industry." Speaker: C. E. Mc Gann. The paper was illustrated with lantern slides. Attendance 32.

April 20, 1920. Paper: "Los Angeles Power Development." Speaker: W. J. Zehfuss. Attendance 25.

April 27, 1920. Paper: "Niagara Falls Electric Development vs. Scenic Development. Speaker: E. D. Rowbottom. Attendance 19.

May 4, 1920. Paper: "Mississippi River Power Development. Speaker: W. B. Jones. The paper was illustrated with slides. Attendance 27.

May 11, 1920. Paper: "The Design of a small Automatic Hydro-Electric Station." Speaker: W. F. Young. Attendance 27.

Stanford University.—April 14, 1920. Business meeting. Attendance 15.

University of Virginia.—May 6, 1920, Mechanical Laboratory. Election of officers as follows: Chairman, Clark Forrest; Secretary-Treasurer, James O'R. Coleman. Paper: "Railway Signaling." Mr. Charles Stephens, of the C. & O. R. R. Professor Rodman read the paper in the absence of Mr. Stephens. Attendance 22.

University of Washington.—April 13, 1920, Forestry Hall. Subjects: "Advantages of the G. E. test for Engineering Graduates," slides and two reels of moving pictures, W. M. Nelson, of the G. E. Company; "The Status of the College Graduate in the Mind of the Professional Electrical Engineer," S. C. Lindsay, P. S. P. & L. Co. Attendance 44.

Yale University.—May 6, 1920, Dunham Laboratory of E. E. Subject: "The Problem of Public Utility Regulation." Speaker: Dr. William McClellan. Attendance 30.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED MAY 21, 1920

ABBOTT, Royal W., Asst. Engineer, U. S. S. New Mexico; San Francisco, Cal.

APPEL, HENRY J., Erecting Engineer, Westinghouse Electric & Mfg. Co., 467, 10th Ave., New York; res., 52 Himrod St., Brooklyn, N. Y.

ASLAKSEN, EINAR, Draftsman, Lord Construction Co., 105 W. 40th St.; res., 142 W. 83rd St., New York, N. Y.

BAILY, BEN POWER, District Manager, Pacific Power & Light Co., 1st National Bank Building, Astoria, Ore.

*BALCH, CLEON F., Distribution & Engineering Div., T. M. E. R. & L. Co., Milwaukee; res., 830 Lake Ave., Racine, Wis.

BARKER, GUY A., Chief Engineer, Central Teresa Sugar Co., Ceiba Hueca, Oriente, Cuba.

BARNES, EDWIN H., Electrical Draftsman, Albert C. Wood, 1411 Walnut St.; res., 1318 N. Frazier St., Philadelphia, Pa,

BATT, CHARLES G., Chief Electrican, Utah Apex Mine, Bingham Canyon, Utah.

BEACOCK, VICTOR ALONZO, Electrical Engineer, Hydro-Electric Power Commission; res., 32 Dundonald St., Toronto, Ont.

BEMIS, EDWIN W., Instructor, Dept. of Electrical Engineering, Worcester Polytechnic Institute; res., 54 Fruit St., Worcester, Mass.

BENEDICT, ROY P., Manager, Chicopee Electric Light Department, Chicopee, Mass.

BINDLER, MICHAEL, Tester of Electrical Apparatus, British Thomson-Houston Co. Ltd.; res., 132 Murray Road, Rugby, England.

*Birkinbine, Olaf W., Asst. Engineer, Birkinbine Engineering Offices, Parkway Bldg., Broad & Cherry Sts., Philadelphia, Pa.

Bischoff, Louis G., Transmission & Protection Engineer, Central Union Telephone Co., 212 W. Washington St., Chicago, Ill.

Bissett, John W., Switchboard Operator, New York Edison Co., 122 Clinton St., New York; res., 39 Victor St., Yonkers, N. Y.

Bloch, Solly, Engineer, International General Electric Co.; res., 105 Seward Place, Schenectady, N. Y.

Bloomfield, Robert E., Consulting and Sales Engineer, Bagdad, Florida.

Bohmann, Robert B., Electrical Draftsman, Allis-Chalmers Mfg. Co., Milwaukee; res., 527 Beverly Road, Shorewood, Wis.

Bolen, Charles A., Plant Inspector, The Bell Tel. Company of Pa.; res., 308 Eicher Ave., Greensburg, Pa.

Bolton, Robert A., Asst. Professor of Drafting, Queen's University, Kingston, Ontario, Can.

Bordeaux, Ephriam P., Draftsman, Sanderson & Porter, 52 William St.; res., 204 W. 106th St., New York, N. Y.

Boss, Earle B., Leading Hand, Turbine Test, General Electric Co., W. Lynn; res., 1 Granite Road, Cliftondale, Mass.

Boutwell, Willard S., Service Engineer, Westinghouse Elec. & Mfg. Co.; res., 1729 Boylston Ave., Seattle, Wash.

Bowler, Willliam E., Sales Training Dept., Norton Company, Worcester; res., 4 Sampson St., Spencer, Mass.

Brodsky, Valdimir P., Electrical Draftsman, Switchboard Div., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Brown, Harrison G., Electrical Draftsman, U. S. Navy Yard, Portsmouth; res., West Rye, N. H.

Brown, Richard, Electrician, American Steel & Wire Co.; res., 217 Lincoln St., Worcester, Mass.

Bugbee, Ralph L., Electrical Designer, Lockwood, Greene & Co., Boston; res., 91 Lincoln St., Melrose, Mass.

Bundock, William A. W., Supervising Electrical Engineer, Dept. of Public Works; res., "Glenora", Henrietta St., Double Bay, Sydney, N. S. W., Aus.

Burman, Charles F., Engineering Dept., Wisconsin Telephone Co., 418 Broadway, Milwaukee, Wis.

Buxton, Vernon R., Sales Switchboard Engineer, Westinghouse Elec. & Mfg. Co., 10 High St., Boston Mass.

*Calligheris, John S., Mechanical Draftsman, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

Carpe, Allen, Student, Electrical Engineering, Columbia University; res., 321 W. 82nd St., New York, N. Y.

Church, Robert A., Service & Inspection Dept., Cutler-Hammer Mfg. Co., 50 Church St., New York, N. Y.

Cigrange, Joseph, Electrician, Electro Construction Co., 1222 St. Paul St., Baltimore, Md.

Clapp, Robert H., Development & Research Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

Creim, Benjamin W., Test Dept., Bureau of Power & Light; res., 2025 Allesandro St., Los Angeles, Cal.

Cross, Raymond J., 1st Asst. Electrician, U. S. S. Leviathan, Hoboken, N. J.

Daunt, Charles A., Electrician, U. S. Government, U. S. Army Base, S. Boston; res., 26 Caton St., Mattapan, Mass. 26

Davis, Carlos, Rail Bonding Foreman, Hudson Valley Railway Co.; res., 18 Washington St., Glens Falls, N. Y.

Debman, Eugene R., Test Engineer, Westinghouse Elec. & Mfg. Co., 467 10th Ave., New York, N. Y.; res., 82 N. 15th St., E. Orange, N. J.

Dee, Thomas C., Instructor in Electrical Engineering, Iowa State College, Ames, Iowa.

de Locht, Victor Lagasse, Chief Engineer, Societe Generale de Chemins de Fer Economiques, 36 rue Capouillet, Bruxelles, Belgium.

Denny, Robert Cary, Operating Engineer, San Joaquin Light & Power Corp., H. & Tulare Sts., Fresno, Cal.

Dewey, Stuart J., Asst. Signal Engineer, C. C. C. & St. L. R. R., Cincinnati, Ohio.

Duff, John E., Squad Man & Checker, Sargent & Lundy, 1412 Edison Bldg., Chicago. Ill.

Dunderdale, Alston, Metropolitan Vickers Electrical Co., Trafford Park, Manchester; res., 11 Springfield Road, Altrincham, Cheshire, Eng.

Dupré, Valentine H., Engineer of Mech. & Elec. Methods, Western Electric Co., Hawthorne Station; res., 4123 W. Monroe St., Chicago, Ill.

Eaton, Frederick W., Elec Engg. Dept., Goodyear Tire & Rubber Co.; res., 1228 W. Pond View Ave., Akron Ohio.

Edmonds, Montrose, Quotation Clerk, General Electric Co., 1000 Lexington Bldg., Baltimore, Md.

Elstun, William P., Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

Evans, James M., Salesman, Westinghouse Elec. & Mfg. Co.; res., 1277 Harrison Ave., Fresno, Cal.

Farmer, George L., Electrical Draftsman, Panama Canal, Balboa Heights, C. Z.

Fay, Carl J., Engineer, Westinghouse Electric Products Co., Mansfield, Ohio.

*Ferguson, Alan H., Power Plant Draftsman, Commonwealth Edison Co.; res., 5403 Prairie Ave., Chicago, Ill.

Fisher, Mordaunt J. M., Foreign Student Course, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Flaherty, Leonard T., Manager, Picton County Electric Co., Stellarton, N. S.

Ford, James E., Senior Testman, New England Tel. & Tel. Co.; res., 271 Powder House Blvd., Somerville, Mass.

Foss, Carl E., Salesman, Victor Electric Corp.; res., 4109 Washington Blvd., Chicago, Ill.

Fowler, Herman M., Electrical Engineer, Wesinghouse Elec. & Mfg. Co.; res., 5515 Brandon St., Seattle, Wash.

French, Ralph W., Salesman, Heavy Traction Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Frick, Clifford H., Supervisor of Operation, Hauto Steam Electric Generating Station, Hauto; res., 238 E. Broad St., Tamaqua, Pa,

Fry, Howard M., Asst. Professor, Physics Dept., Lehigh University; res., 726 Avenue H., Bethlehem, Pa.

*Fryburg, Warren, (Partner), Effandee Motor Trucking Exchange, 32 Union Square; res., 159 W. 77th St., New York, N. Y.

Geder, John J., Electrical Estimating Engineer, Allis-Chalmers Mfg. Co., West Allis, Wis.

Gemmill, Melvin E., Electrican, Bethlehem Shipbuilding Corp., Sparrow Point; res., 3522 E. Fairmount Ave., Baltimore, Md.

Ghosh, Jagabandhu, Pupil Engineer, Charing Cross, West End & City Electricity Supply Co., Stratford; res., 58 Redcliffe Road, London, S. W. 10, Eng.

Gieselberg, George H., Chief Engineer & Mechanical Supt., Gimbel Brothers, 6th Ave. & 33rd St., New York; res., 683 Briggs Ave., Richmond Hill, N. Y.

*Gilchrist, Frederick W., Sales Engineer, The Cutler-Hammer Mfg. Co.; res., 222 11th St., Milwaukee, Wis.

Grunfield, Maurice, 126 East 95th Street, New York, N. Y.

Grunsky, Clotilde, Associate Editor, *Journal of Electricity*, 531 Rialto Bldg., San Francisco, Cal.

Harris, Leonard F., Engineering Asst., New York Telephone Co., 195 Broadway; res., 300 E. 143rd St., New York, N. Y.

Harvey, Lloyd B., Electrical Worker, Instrument Dept., U. S. Navy Yard, Portsmouth; res., Greenland, N. H.

Hatz, Earl W., Engineering Div., Electrical Distribution Dept., Milwaukee Elec. Ry. & Light Co., Milwaukee, Wis.

Hecht, J. Bernard, General Construction Engineer, Tri-State Tel. & Tel. Co.; res., 1839 Ashland Ave., St. Paul, Minn.

Heckman, Chester L., Salesman, Westinghouse Electric & Mfg. Co., 1012 Park Bldg., Worcester, Mass.

*Heffner, Roy E., Instructor of Electrical Engineering Dept., Sibley College, Cornell University, Ithaca, N. Y.

Henritze, Richard James, Supervisor, Coil and Insulation, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Hodge, Thomas J., Inspector, Engineering Dept., Potomac Electric Power Co., Washington; res., 215 Buffalo Ave., Takoma Park, Washington, D. C.

*Hoey, William B., Research Work, Engg. Dept., Electric Service Supplies Co., 17th & Cambria Sts., Philadelphia, Pa.

Hollenbeck, Charles H., Special Apprentice, N. Y., N. H. & H. R. R., Van Nest & Matthews Ave.; res., 79 Mahlstedt Place, New Rochelle, N. Y.

*Howe, Harvey W., Manager, Engineering Dept., Beckett Electric Co., 206 Linz Bldg., Dallas, Texas.

HOWELL, GEORGE E., Electrical Worker, Meter Dept., U. S. Navy Yard; res., 226 Austin St., Portsmouth, N. H.

HUSTED, NORRIS C., Sales Engineer, Hubbard & Co., Granite Bldg., Pittsburgh, Pa.

ITHIER, GASTON P. P. J., Managing Director, Societe Generale de Chemins de Fer Economiques, 54 Rue de Namur, Bruxelles, Belgium.

JAMES, HERBERT M., Electrical Engineer, Hudson Coal Co.; res., 318 Taylor Ave., Scranton, Pa.

JOHNSON, EARL A., Junior Electrical Engineer, Transit Construction Commission, Electrical Laboratory, 49 Lafayette St., New York, N. Y.

KALAPESI, M. J., H. M. Government Electrican, The Residency, Tarshyne, Aden., Arabia.

KALMBACH, MAURICE F., Transmission & Protection Engineer, Wisconsin Telephone Co.; res., 354 37th St., Milwaukee, Wis.

KELLEY, THOMAS C., Testing Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 414 Montview Place, Wilkinsburg, Pa.

KEYSER, WILLIAM H., Sub-Foreman, Electric Construction, Puget Sound Traction, Light & Power Co.; res., 2426 W. 60th St., Seattle, Wash.

KHAN, M. ALI, Electrical Engineering, General Electric Co.; res., 21 Ferry St., Schenectady, N. Y.

KIDWELL, HERBERT W., Asst. Electrical Engineer, W. &. O. D. Railway, 3611 M St., Washington, D. C.

KILLAM, LAFAYETTE W., Foreman, Armature Winder, Westinhouse Elec. & Mfg. Co., New York; res., 1081 71st St., Brooklyn N. Y.

KING, EARL B., Electrolysis Engineer, Central Union Telephone Co.; res., 2934 N. Penn St., Indianapolis, Ind.

KIRBY, JOSEPH H., Electrical Contracting, H. B. Hustin & Son, Jackson, Tenn.

KNICKERBOCKER, WALTER G., Office Manager, H. F. Fleming Construction Co., Marysville, Mich.

LAUBER, CALVIN G., Engineer, National Board of Fire Underwriters, 76 William St., New York, N. Y.

LEITE, ARNALDO F., Electrical Engineer, Wilkinsburg, Pa.

LEWTHWAITE, FRED A., Substation Engineer, Public Works Dept., Addington Substation, Christchurch, N. Z.

*LIKELY, ROBERT D., Testing Dept., General Electric Co.; res., 33 N. Ferry St., Schenectady, N. Y.

LINDZEY, JOHN O., Tester, Diehl Manufacturing Co., Elizabethport; res., 423 Park Ave., Plainfield, N. J.

LONG, ORVILLE F., Electrical Engineer, Kelsey Wheel Co. Inc., Memphis, Tenn.

LOOS, ALDO H., Electrical Draftsman, Kansas City Light & Power Co.; res., 1829 E. 7th St., Kansas City, Mo.

LOSHING, CLEMENT K., Elec. Engg., Cleveland Electric Illuminating Co., 308 Illuminating Bldg., Cleveland, Ohio.

LOVETT, FREMONT L., Distribution Engineer, Worcester Electric Light Co., 66 Faraday St., Worcester, Mass.

*LOWELL, GLEN J., Electrical Engineer, General Electric Co.; res., 3 Swan St., Schenectady, N. Y.

LUICHINGER, MARTIN J., Field Engineer (Long Distance Lines), Central Union Tel. Co.; res., 615 W. 32nd St., Indianapolis, Ind.

MACDONALD, KENNETH V., Lock Operator (Electrical), New York State Barge Canal; res., 152 W. 3rd St., Fulton, N. Y.

MACDONALD, MARTIN W., System, Operator, Hagerstown & Frederick Co., & Operated Co's. Hagerstown, Md.

MACNELLEY, CHARLES J., Material Foreman, The Panama Canal, Balboa, C. Z.

MACPHERSON, KENNETH P., Lecturer, in Electrical Engineering, Queen's University, Kingston, Ont.

MAGEE, FRANK, L., Salesman, Aluminum Company of America; res., 196 Norton St., New Haven, Conn.

MAGNUSON, AXEL H., Chief Electrician, The Graton & Knight & Mfg. Co., 344 Franklin St.; res., 19 Altmont Ave., Worcester, Mass.

MAKOUS, LAWRENCE, Draftsman, Elec. Dept., Allis-Chalmers Mfg. Co., W. Allis, Wis.

MARQUIS, JAMES B., Managing, Telephone Company, Norwich, N. Y.

MARYATT, ELMER F., Electrical Draftsman, Stone & Webster, 301 Holbrook Bldg., San Francisco, Cal.

MAXWELL, JOSEPH H., Asst. Supt. of Testing & Standardization, Elec. Light Dept., S. M. C., Sydney, Australia.

McCLEERY, HAROLD L., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1128 Franklin Ave., Wilkinsburg, Pa.

McCORMICK, FRED J., Outside Plant Engineer, Wisconsin Telephone Co.; res., 465 Frederick Ave., Milwaukee, Wis.

McDONALD, JAMES W., Engineering Asst., Public Service Electric Co., Newark; res., 90 Hollywood Ave., E. Orange, N. J.

McDOUGALL, JAMES C., Engineer, Westinghouse Electric & Mfg. Co., 1400 Alaska Bldg., Seattle, Wash.

MEYERS, PHILIP M., Supt., Ferracute Machine Co.; res., 50 North Giles St., Bridgeton, N. J.

MILLER, HENRY J., General Electric Co.; res., 6159 Kenwood Ave., Chicago, Ill.

MINTZNER, WATKINS F., Construction Engineer, Service Dept., Canadian Westinghouse Co. Ltd., Hamilton, Ont., Canada.

MISSO, GEORGE E., Asst. Engineer, Colombo Electric Tramways & Lighting Co., Colombo, Ceylon.

MITCHELL, HAROLD J., Investigating Engineer, Westinghouse Elec. & Mfg. Co., 467 10th Ave., New York; res., 42 2nd St., Elmhurst, N. Y.

MONTGOMERY, JOHN V., Engineer, Electrical Division, Engg. Dept., Dwight P. Robinson & Co., Inc., 61 Broadway, New York, N. Y.

MOORE, ERIC M., Local Manager, Washington Coast Utilities & Vashon L. & P. Co., Portage, Wash.

MOORHEAD, O. B., President & Chief Engineer, Moorhead Laboratories Inc.; res., 15 26th Ave., San Francisco, Cal.

MOREHOUSE, ADEN K., Division Equipment Foreman, Pacific Tel. & Tel. Co., Sheldon Bldg., San Francisco, Cal.

MORGAN, FRANK I., Electrical Inspector, Penn. Water & Power Co., Holtwood, Pa.

MORRONI, ANTHONY J., Chief Electrician, Central Armature Works, 635 D St., N. W., Washington, D. C.

MOSMAN, CHARLES F., Electrical Testing & Laboratory Work, Factory Mutual Fire Insurance Co. Laboratories, Boston; res., 29 Webster St., Atlantic, 71, Mass.

MULKEY, SAM F., Wiremans' Helper, Union Electric Light & Power Co.; res., 3963 W. Pine St., St. Louis, Mo.

MURRAY, WILLIAM ARTHUR, Intructor in Electrical Engineering, University of Idaho; res., 425 Third St., Moscow, Idaho.

MYERS, CLYDE J., Salesman, Electric Motors, Holtzer-Cabot Electric Co., 1051-52 Book Bldg., Detroit, Mich.

NASH, FREDERICK H., Research Engineer, Empire Gasoline Co., Bartlesville, Okla.

NELSON, EDWARD L., Engineering Dept., Western Electric Co., 463 West St., New York, N. Y.

NEUSTEDTER, WALTER J., Engineer, Cutler-Hammer Mfg. Co.; res., 1207, 25th St., Milwaukee, Wis.

NEWTON, WILLIAM J., Electrical Engineer & Patent Attorney, Harvey Hubbell, Inc., Bridgeport, Conn.

NISTRY, NUSSERWANJI R., Statistician, Tata Hydro-Electric Power Supply Co., Ltd., Bombay 2, India.

NOPPEL, EDWARD P., Asst. Mechanical Engineer, American Railways Co.; res., 2508 So. Colorado St., Philadelphia, Pa.

NORCROSS, JOSIAH C., Asst. Supt., Installations Dept., Edison Elec. Ill. Co. of Boston, 39 Boylston St., Boston (10), Mass.

O'DEA, MATTHEW F., District Office Inspector, Cutler-Hammer Mfg. Co., 77 Franklin St., Boston, Mass.

OLDHAM, JOSEPH K., Engineering Dept., Worcester Electric Light Co., 66 Faraday St., Worcester, Mass.

OWEN, RALPH J., Sales Engineer, Mechanical Appliance Co., 133 Stewart St., Milwaukee, Wis.

PARKERSON, LOUIS R., Supt. of Distribution, Consolidated Gas Company of New Jersey, 176 Broadway, Long Branch, N. J.

PARKINSON, GEORGE V., Chief Electrical Engineer, Turbine & Elec. Depts., Cuba Cane Sugar Corp., Apartado 1270, Havana, Cuba.

PAYNE, EDWARD B., Engineer, Western Electric Co., 463 West St., New York, N. Y.

PERO, BERTRAM S., Power & Mining Engg. Dept., General Electric Co., Schenectady, N. Y.

POMEROY, JOSEPH GEORGE, Electrician, City Light Dept., County-City Bldg., Seattle, Wash.

Poupart, Ernest, Electrical Engineer, Lake Shore Mines, Ltd., Kirkland Lake, Ontario, Can.

Pride, Alfred W., Engineer, Electric Auto-Lite Corp.; res., 356 Winthrop St., Toledo, Ohio.

Reading, Robert S., Electrical Engineer, Stone & Webster, Houston, Texas.

*Reed, Myron G., Local Manager, Central Mexico Light & Power Co., Irapuato, Gto., Mexico.

Reynolds, Henry C., Electrical & Special Hazard Engineer, Southeastern Underwriters' Association, 204 Pollock Bldg., Mobile, Ala.

Ricciardi, Salvatore D., Engineering Asst., Bell Telephone Co. of Pa.; res., 5310 Chancellor St., Philadelphia, Pa.

Robinson, Gilbert, Asst. Electrical Engineer, Edison Electric Illuminating Company of Boston, 39 Boylston St., Boston, Mass.

Roe, Arthur C., Asst. Foreman, Westinghouse Elec. & Mfg. Co., 467 10th Ave.; res., 2311 Grand Ave., New York, N. Y.

Rosen, Nathan, Electrical Draftsman, U. S. Navy Yard, Portsmouth, N. H.

Ross, Harold D., Electrical Engineer, General Electric Co.; res., 65 Livingstone Ave., Pittsfield, Mass.

Ross, Lindsley W., Telephone Engineer, The Pacific Tel. & Tel. Co.; res., 590 Main St., Portland, Ore.

*Rothschild, Harold L., Sales Engineer, St. Paul Electric Co., St. Paul, Minn.; res., Le Mars, Ia.

Rushton, Frederick, Switchboard Operator, Hydro Electric Power Commission of Ontario; res., 747 Annette St., Toronto, Ont.

Scott, Bernard W., Asst. to Electrical Engineer, American Woolen Co., Boston; res., 17 Saratoga St., Lawrence, Mass.

Seabra, José R., Electrical Engineer, Brazilian Government: Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Shaw, J. B., Electrican, West Penn Power Co.; res., 118 Truby St., Greensburg, Pa.

Simmons, Moses H., General Electric Works, The New Jersey Zinc Co., Franklin, N. J.

Sinclair, Charles G. Jr., Telephone Engineer, New York Telephone Company, 203 Broadway, New York, N. Y.

*Singh, Charnjit, Priest, Stockton, Cal.

Smith, Charles D., Electrical Foreman, Engg. Dept., E. I. Du Pont de Nemours Co., So. Windham, Maine.

Smith, Charles G., Chief Electrican, Cosden & Co., West Tulsa Refinery; res., 115 Frisco St., W. Tulsa, Okla.

Smith, Don F., Transmission Engineer, Pacific Tel. & Tel. Co., 507 Sheldon Bldg., San Francisco, Cal.

Smith, Frederick William, Electrical Dept., St. Elizabeth's Hospital, Washington, D. C.

Smith, Glen H., Engineer, Outside Construction, City of Seattle, Lighting Dept.; res., 4269 Linden Ave., Seattle, Wash.

Snow, Arthur F., Service Engineer, Worcester Electric Light Co.; res., 209 Chandler St., Worcester, Mass.

Snow, Harold M., Operator, Hartwig Theatre; res., 910 S. Washington St., Dillon, Mont.

Steortz, Charles M., Foreman, Battery Charging Station, Panama Canal, Cristobal, C. Z.

Stevens, Vergil, Engineering Dept., Tri-State Tel. & Tel. Co., Merriam Park, St. Paul, Minn.

Strachan, Harley A., Production Dept., Century Electric Co.; res., 4311 Lee Ave., St. Louis, Mo.

Stubinger, Eugene McAlpin, Engineering Draftsman, 1530 Healey Bldg., Atlanta, Ga.

Sturtevant, Benjamin J., Electrical Engineer, The Cutler-Hammer Mfg. Co., Milwaukee, Wis.

Sullivan, M. E., Construction Supt., General Electric Co.; res., 3523 Bosworth Ave., Chicago, Ill.

Swann, Edwin H., Telephone Engineer, Bell Telephone Company of Pa.; res., 4911 Walnut St., Philadelphia, Pa.

Swicker, Lester C., Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

Takahashi, Kanejiro, Electrical Engineer, Yokohama Electric Wire Works, Yokohama, Japan.

Temme, Alfred M., Electrical Engineer, Westinghouse Elec. & Mfg. Co., 467 10th Ave., New York; res., 2511 Woodbine St., Ridgewood, N. Y.

Thayer, Charles H., Electrical Dept., Worcester Polytechnic Institute, Worcester, Mass.

Tischler, Napoleon, Switchboard Designer, Westinghouse Elec. & Mfg. Co., 467 10th Ave., New York, N. Y.

Torrens, Robert J., Electrical Engineer, U. S. Naval Observatory, Washington, D. C.

Townsend, Herbert K., Chief Clerk to Electrical Engineer, S. F. O. T. Railways, 22nd & Grove Sts., Oakland, Cal.

Transtrom, Henry L., Electrical Worker, Central Armature Works, 7 & D Sts.; res., 6615 1st St., N.W., Washington, D.C.

Tucker, Francis, Manager, Wiring Dept., Standard Electrical Elevator Co., 118 E. Pratt St., Baltimore, Md.

Tufty, Harold G., Graduate Student, University of Wisconsin; res., 213 Lake St., Madison, Wis.

Tyzzer, Howard J., Radio Engineer, American Radio & Research Corp., Medford Hillside; res., 13 Upham St., Melrose, Mass.

ASSOCIATES REELECTED MAY 21, 1920

Bridges, J. Earle, District Equipment Foreman, Michigan State Telephone Co., 406 Central State Bldg., Jackson, Mich.

D'Huny, Fernand Emile, Central Office Engineer, Western Union Telegraph Co., 195 Broadway, New York, N. Y.

Gilman, Ralph E., Electrical Engineer, Westinghouse Electric & Manufacturing Co., E. Pittsburgh, Pa.

Hurley, Wallace P., Sales Engineer, Westinghouse Elec. & Mfg. Co., 165 Broadway, New York, N. Y.

Nye, Henry V., Sales Engineer, Allis-Chalmers Mfg. Co.; res., 758 75th Ave., W. Allis, Wis.

Phillips, Edwin T., Supt. of Power, The Eastern Connecticut Power Co.; res., 55 Broad St., Norwich, Conn.

Spencer, Fredrick A., Professor of Electrical Engineering, Norwich University, Northfield, Vermont.

MEMBERS ELECTED MAY 21, 1920

ANCIAUX, LOUIS, Manager, Arequipa Tramways Co., Casilla 176, Arequipa, Peru, S. A.

CURTIS, EGBERT H., Estimating Engineer, Lord Electric & Lord Construction Co., 105 West 40th St., New York, N. Y.

BOWMAN, EDWARD C., Engineer of Transmission, Long Lines Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

DODGE, HARRY A., Electrical Engineer, Lockwood, Greene & Co., 101 Park Ave., New York, N. Y.

EMERSON, CHERRY L., Power Engineer, Robert & Co., Tufts Bldg., Atlanta, Ga.

FULLER, CARL T., Engineer, Edison Lamp Works, General Electric Co., Harrison, N. J.

FYKE, J. LOWELL, Asst. Supt., Electrical Dept., Allis-Chalmers Mfg. Co., W. Allis; res., 480 52nd St., Milwaukee, Wis.

HALL, THEODORE, Engineer, Research Dept., Sperry Gyroscope Co., Manhattan Bridge Plaza, Brooklyn, N. Y.

HARDY, GEORGE M., Supt., Distribution & Service, Worcester Electric Light Co.; res., 37 June St., Worcester, Mass.

JOHNSON, CLARENCE C., Vice-President in charge of Engineering & Plant, American District Telegraph Co., 30 Church St., New York, N. Y.

PACKWOOD, GEORGE H., JR., Electrical Engineer, G. E. Smith & Company, 2073 Railway Exchange Bldg., St. Louis, Mo.

PEARSON, HAROLD J. C., Asst. to Manager, and in Charge of Electrical work, Walker Electric & Plumbing Co., Atlanta, Ga.

PENN, MARION, Plant Engineer, Public Service Electric Co. of N. J., Essex Station, Point-no-Point, Newark, N. J.

PERCIVAL, HARRY S., Engineer of Outside Plant. Long Lines Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

PERRIN, CECIL M., Distribution Engineer, Municipal Electricity Dept., Shanghai, China.

POMEROL, LAURENT, Sub-Director, Energia Electrica de Cataluna; res., 305 Mallorca 4°-2a, Barcelona, Spain.

SCHNABELT, FRANK J., Works Engineer, Western Electric Co. Inc., Hawthorne Plant; res., 930 N. Lawler Ave., Chicago, Ill.

SMITH, MARSDEN C., Engineer in charge of Electrical Div., Dept. of Public Utilities, City of Richmond, Richmond, Va.

TRANSFERRED TO GRADE OF MEMBER MAY 21, 1920

ATKINSON, KERR, Engineer, with Roderick D. Donaldson, New York, N. Y.

CANADA, WILLIAM J., Electrical Engineer, Stone & Webster, Boston, Mass.

FAIR, RICHARD H., Outside Plant Engineer, Bell Telephone System, Northwestern Group, Omaha, Neb.

HOWLAND, RALPH B., Assistant Electrical Engineer, Dwight P. Robinson & Co. Inc., New York, N. Y.

IVES, JOHN NASH, Electrical Engineer, Lockwood, Greene & Co., Boston, Mass.

McEACHRON, KARL B., Research Assistant, Engineering Experiment Station, Purdue University, Lafayette, Ind.

REGAL, A. P., Electrical Engineer, Philadelphia Rubber Works Co., Akron, O.

SCHLUSS. KURT C., Supt. of Power & Equipment, Tacoma Ry. & Power Co., Puget Sound Electric Ry., Puget Sound Traction Lt. & Pr. Co. (Tacoma Div.), Tacoma, Wash.

STANFORD, F. C., Chief Electrician, Cleveland Cliffs Iron Co., Ishpeming, Mich.

STELZNER, W. B., Professor of Electrical Engineering, University of Arkansas, Fayetteville, Ark.

THORNTON, FRANK, JR., Chief Engineer, Westinghouse Electric Products Co., Mansfield, O.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at meetings held May 10 and 17, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

BIBBINS, JAMES R., Supervising Engineer, The Arnold Co., Chicago, Ill.

BYLLESBY, HENRY M., President, H. M. Byllesby Co., President, Standard Gas & Electric Co., Chicago, Ill.

CALDWELL, HARRY L., Engr. of Elec. Distribution, Public Service Co. of Northern Illinois, Chicago, Ill.

CRAVATH, JAMES R., Member of firm, Fowle & Cravath, Chicago, Ill.

DEL MAR, WILLIAM A., Chief Engineer, Habirshaw Electric Cable Co., New York, N. Y.

ELLS, FREDERICK W., Chief Engineer, Northwestern Mfg. Co., Milwaukee, Wis.

GEAR, HARRY B., Engr. of Distribution, Commonwealth Edison Co., Chicago, Ill.

GRAHAM, EARL A., General Manager & Chief Engineer, Compania Panamena de Fuerza y Luz, Ancon, C. Z.

HALL, CHESTER I., Engineer, Experimental Laboratory, General Electric Co., Fort Wayne, Ind.

KING, ARTHUR C., President, Illinois Appraisal Co., Chicago, Ill.

MILTON, TALIAFERRO, Manager, Chicago Office, Electric Storage Battery Co., Chicago, Ill.

MORTENSEN, NIELS L., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

MORTENSEN, SOREN H., Electrical Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

MOUNTAIN, JOHN T., Asst. to Chief Operating Engineer, Commonwealth Edison Co., Chicago, Ill.

REINHARD, LOUIS F., Chief Engineer, Mechanical Appliance Co., Milwaukee, Wis.

SCHWEITZER, EDMUND O., Chief Testing Engineer, Commonwealth Edison Co., Chicago, Ill.

To Grade of Member

ADAMS, HARRY H., Supt. Shops & Equipment, Chicago Surface Lines, Chicago, Ill.

ALLEN, N. L., Chief Electrical Engineer, American Zinc Lead & Smelting Co., Mascot, Tenn.

ANNETT, FRED A., Associate Editor *Power*, New York, N. Y.

BACON, FRANK R., President, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

BELL, WILLIAM I., Mechanical & Electrical Engineer, South Park Commissioners, Chicago, Ill.

BOOTH, WILLIAM K., Secretary & Chief Engineer, Booth Electric Furnace Co., Chicago, Ill.

BOWMAN, DONALD, Engineer of Apparatus & Materials, Commonwealth Edison Co., Chicago, Ill.

BRACK, G. S., Electrical Engineer, The Sanitary District of Chicago, Chicago, Ill.

BRITTON, JOHN A., Vice-President & General Manager, Pacific Gas & Electric Co., San Francisco, Cal.

BROWN, CARLTON E., Meter Engineer, Commonwealth Edison Co., Chicago, Ill.

BURR, FRANK D., Power Engineer, Denver Gas & Electric Light Co., Denver, Colo.

CRELLIN, EARLE A., Electrical Engineer with Leland S. Rosener, San Francisco, Cal.

CURTIS, LESLIE F., Asst. Professor of Electrical Engineering, University of Washington, Seattle, Wash.

d'HUMY, FERNAND E., Central Office Engineer, Western Union Telegraph Co., New York, N. Y.

EDWARDS, STANLEY R., Editor, *Telephony*, Chicago, Ill.

FLANDERS, MILTON M., Charge Dept. of Electrical Tests, Bliss Electrical School, Washington, D. C.

FLEET, ARTHUR H., Manager, Specialty Dept., Cutler-Hammer Mfg. Co., Milwaukee, Wis.

FOX, EDWIN G., Electrical Engineer, Steel & Tube Co. of America, Indiana Harbor, Ind.

GILMAN, RALPH E., Electrical Engineer, Westinghouse Electric & Mfg, Co., E. Pittsburg, Pa.

HUBBARD, FRANK H., Patent Attorney, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

JACKSON, WILLIAM A., President, W. A. Jackson Co., Chicago, Ill.

JOHNSON, ALVIN W., Elec. Engr. in Charge General Construction, General Electric Co., Chicago, Ill.

KAMMERMAN, JOHN O., Asst. Professor of Electrical Engineering, University of Wisconsin, Madison, Wis.

LAUE, GILBERT E., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

LUNN, ERNEST, Chief Electrician, The Pullman Co., Chicago, Ill.

McHENRY, Manager, Walkerville Hydro-Electric System, Walkerville, Ont.

MORSE, ROBERT E., Engineer-in-Charge, Henry R. Kent & Co., Rutherford, N. J.

NYE, HENRY V., Special Sales Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

O'CONNOR, ALBERT, Manager, Switchboard Dept., Westinghouse Elec. & Mfg. Co., Boston, Mass.

OSTRANDER, JOHN K., Electrical Engineer, Dwight P. Robinson & Co., New York, N. Y.

PARKER, ROSS I., Apparatus Sales Dept., General Electric Co., Chicago, Ill.

PETROWSKY, JOHN F., Designing Engineer, A. C. Engineering Dept., Crocker-Wheeler Co., Ampere, N. J.

REINHARD, GUSTAV A., Asst. Chief Engineer, Mechanical Appliance Co., Milwaukee, Wis.

RUSSEL, FRANK J., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

SCHOU, THEODORE, Chief Engineer, Ideal Electric & Manufacturing Co., Mansfield, O.

SEIBERT, WILLIAM J., Asst. Chief Electrician, General Electric Co., Erie, Pa.

SPENCER, FREDERICK A., Professor of Electrical Engineering, Norwich University, Northfield, Vt.

WADE, HENRY N., Development Engineer (Electrical), Cutler-Hammer Mfg. Co., Milwaukee, Wis.

WATT, GEORGE Y., Century Electric Co., St. Louis, Mo.

WILKINSON, C. T., Engineer & Manager, Milliken Manufacturing Syndicate, London, England

WILKINSON, KENNETH L., Charge Foreign Wire Relations, American Telephone & Telegraph Co., New York, N. Y.

WOODCOCK, LANCELOT R., Resident Engineer, Riegos y Fuerza del Ebro, Barcelona, Spain

WURTH, WILLIAM, Engineer Statistics, The Peoples Gas Light & Coke Co., Chicago, Ill.

WYNNE, VALENTINE C., Consulting Engineer, Albany, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member, objecting to the election of any of these candidates should so inform the Secretary before June 30, 1920.

Addis, Judd, Seattle, Wash.
Almquist, Paul B., Seattle, Wash.
Anderson, John F., Bellville, Ont.
Anglemyer, Wilbur F., Chicago, Ill.
Andresen, Kilmar, Chicago, Ill.
Anson, Stuart, M., Worcester, Mass.
Arenberg, Albert L., Chicago, Ill.
Bakesef, Samuel, (Member), Los Angeles, Cal.
Barmack, Boris J., Chicago, Ill.
Bates, Albert W., New Haven, Conn.
Battern, Algy R., Carroll, Iowa
Bayer, Edward F., Jr., Mt. Vernon, N. Y.
Beckel, George J., Chicago, Ill.
Bedford, Lynn N., Chicago, Ill.
Benham, Frank A., (Member), Boston, Mass.
Bente, Saunders H., (Member), Kankakee, Ill.
Bentz, Henry C., St. Paul, Minn.
Bickel, Joseph W., Chicago Heights, Ill.
Bickering, Albert E., Sault Ste Marie, Ont.
Bliss, William W., San Francisco, Cal.
Bouska, James W., Chicago, Ill.
Bowden, William C., Middle Village, L. I.
Boyden, Davis S., (Member), Boston, Mass.
Bradshaw, George H., Niagara Falls, Ont.
Brockman, Francis C., Roselle Park, N. J.
Brokmann, John, Chicago, Ill.
Brown, W. R., Milwaukee, Wis.
Brueckner, Julius R., Detroit, Mich.
Buck, Kendall, Dieringer, Wash.
Buford, Paschal, Austin, Texas.
Bunker, Edmund C., Charleston, S. C.
Burrows, Robert P., (Member), Cleveland, Ohio

STUDENTS ENROLLED May, 21 1920

MAY 21, 1920

11436 Haigh, Richard A., University of Michigan
11437 Gaines, Le Grand A., Jr., University of Michigan
11438 Brede, Erwin F., University of Michigan
11439 Merritt, Frank B., Rutgers College
11440 Bolles, Carleton F., Worcester Polytechnic Institute
11441 Leonard, Richard S., Worcester Polytechnic Institute
11442 Dunbar, John R., McGill University
11443 Corrigan, Thomas P., New York Electrical School
11444 Landwersilk, Edward J., Pratt Institute
11445 Parrott, John A., Catholic University of America
11446 Holland, Norman N., Johns Hopkins University
11447 Brewster, Louis C., Case School of Applied Science
11448 Williams, Joseph S., Case School of Applied Science
11449 Childs, Maynard H., Case School of Applied Science
11450 Votypka, Yaro H., Case School of Applied Science
11451 Nyerges, William S., Case School of Applied Science
11452 Stone, Leland, Worcester Polytechnic Institute
11453 Nein, Harry R., Pennsylvania State College
11454 Stover, Earl B., University of Illinois
11455 Dawson, Heber W., McGill University
11456 Morse, Lyle J., Worcester Polytechnic Institute
11457 Graff, Milton W., Worcester Polytechnic Institute
11458 Douglas, Forest M., Jr., Worcester Polytechnic Institute
11459 Meyrick, Gordon S., University of Wisconsin
11460 Keller, John J., Purdue University
11461 Brown, Campbell A., Purdue University
11462 Kaufman, Aaron R., Purdue University
11463 Mitchell, Chester F., Purdue University
11464 Freezee, Walter D., Purdue University
11465 Moore, Earl R., Purdue University
11466 Bailey, George H., Purdue University
11467 Meissner, Herman A., Case School of Applied Science
11468 King, Harold, Case School of Applied Science
11469 Friedman, Bernhard D., Case School of Applied Science
11470 Backus, Ray A., Michigan Agricultural College
11471 Moore, Edward R., Pennsylvania State College
11472 Cooley, Gilbert, University of Minnesota
11473 Inouye, Noborn, Johns Hopkins University
11474 Ault, E. Stanley, Johns Hopkins University
11475 Spartana, Anthony R., Johns Hopkins University
11476 Anderson, Arvid E., Worcester Polytechnic Institute
11477 Beil, Cecil N., Oklahoma A. & M. College
11478 Black, Harold S., Worcester Polytechnic Institute
11479 Arthur, Stanley W., Worcester Polytechnic Institute
11480 Parnell, Eric, McGill University
11481 Bagby, Raymond J., Worcester Polytechnic Institute
11482 Whelen, Morland P., McGill University
11483 Brush, Waite S., Rensselaer Polytechnic Institute
11484 Bourne, Roland B., Rensselaer Polytechnic Institute
11485 Douglass, Dwight, Rensselaer Polytechnic Institute
11486 Guernsey, Charles W., Rensselaer Polytechnic Institute
11487 La Riviere, John B., Rensselaer Polytechnic Institute
11488 Ketcham, Earl D., Rensselaer Polytechnic Institute
11489 Martin, Edmund B., Rensselaer Polytechnic Institute
11490 Martinez, Lauro C., Rensselaer Polytechnic Institute
11491 Michon, Alfred E., Rensselaer Polytechnic Institute
11492 Mitchell, Erwin H., Rensselaer Polytechnic Institute
11493 Raynor, Lucian B., Rensselaer Polytechnic Institute
11494 Reynolds, James J., Rensselaer Polytechnic Institute
11495 Smith, Reginald S., Rensselaer Polytechnic Institute
11496 Smith, Seneca S., Jr., Rensselaer Polytechnic Institute
11497 Stafford, John K., Rensselaer Polytechnic Institute
11498 Snyder, William B., Rensselaer Polytechnic Institute
11499 Stamper, Hamilton A., Rensselaer Polytechnic Institute
11500 Tate, F. Spencer, Rensselaer Polytechnic Institute
11501 Trevett, Harold N., Rensselaer Polytechnic Institute
11502 Kurtz, Henry J., Michigan Agricultural College
11503 Gaige, Lisle E., Rutgers College
11504 Chappelka, Alfred R., Case School of Applied Science
11505 Salkheld, Elbridge W., Case School of Applied Science
11506 Kaehni, Frank J., Case School of Applied Science
11507 Van Sickle, Miles E., Carnegie Institute of Technology
11508 Johnston, Lloyd E., Johns Hopkins University
11509 Isaac, Rosa D., University of California
11510 Adelson, Abraham M., University of Washington
11511 Blakeley, Loren E., California Institute of Technology
11512 Abbott, L. Emerson, Ohio Northern University
11513 Biggin, Harold L., Alabama Polytechnic Institute
11514 Gentzel, Paul M., Pennsylvania State College
11515 Hunting, Harold S., Worcester Polytechnic Institute
11516 Ashley, David P., Worcester Polytechnic Institute
11517 Reimann, Edward C., Armour Institute of Technology
11518 Pope, Robert, Stevens Institute of Technology
11519 Strauss, Jacob S., Cooper Union
11520 Fuog, Arnold T., Armour Institute of Technology
11521 Duck, Emerson, School of Engineering of Milwaukee
11522 Martin, Alvin A., School of Engineering of Milwaukee
11523 Oliver, Arnold J., School of Engineering of Milwaukee
11524 Karin, Harvey G., School of Engineering of Milwaukee
11525 Grob, John J., School of Engineering of Milwaukee
11526 Marshall, Russell H., Franklin Union Classes
11527 Deering, Lawrence E., University of Maine
11528 Merry, Silas E., University of Maine
11529 Haatanen, George, Tri-State College of Engineering
11530 Hoidahl, Edward M., Tri-State College of Engineering
11531 Jendrasiak, Telesphor J., Carnegie Institute of Technology
11532 Thurston, Lester R., University of Maine
11533 Jones, John C., University of Texas
11534 Owsley, Joseph H., University of Washington
11535 Brokaw, Charles A., University of Washington
11536 Tynan, Thomas G., Cooper Union
11537 McLain, Henry McC., West Virginia University
11538 Kern, Raymond F., Pennsylvania State College
11539 Grover, George U., Pennsylvania State College
11540 Rosenblum, Max, Brooklyn Polytechnic Institute
11541 Diemer, Irving C., Ohio Northern University
11542 Poland, Frank F., Johns Hopkins University
11543 Trayser, Anthony C., University of Virginia
11544 Hearn, George K., Brooklyn Polytechnic Institute
11545 Stewart, George D., Pratt Institute
11546 Hall, Milton E., Pratt Institute
11547 Trumbull, Arthur J., Columbia University
11548 Winterhalter, Theodore S., Pratt Institute
11549 Walsh, Henry A., Wentworth Institute
11550 Meader, Raymond B., New Hampshire College
11551 Scherer, Edward O., Pennsylvania State College
11552 Condon, Frank W., University of Illinois
11553 Butler, Henry R., University of Maine
11554 Barnard, Walter F., Pennsylvania State College
11555 Brewster, Oswald C., Cornell University
11556 Will, Irving M., Worcester Polytechnic Institute
11557 Marion Frederick R., Stevens Institute of Technology
11558 Schippel, Walter H., McGill University
11559 Zeigler, John C., Pennsylvania State College
11560 Hobbs, George V., Johns Hopkins University
11561 Moir, James G., Jr., Massachusetts Institute of Technology
11562 Kemp, Erford C., Wentworth Institute
11563 Warthen, Charles F., Johns Hopkins University
11564 Von Eiff, Herman A., Johns Hopkins University
11565 Fabling, Walter D., Los Angeles Polytechnic High School
11566 Hacker, Louis W., McGill University
11567 Jennings, Frank B., Pratt Institute
11568 Copeland, William O., Pratt Institute
11569 Beutler, Erwin G., Pratt Institute
11570 Hass, William V., Pratt Institute
11571 Smith, Harry L., Pratt Institute
11572 Cook, Jerome E., Pratt Institute
11573 Wahmann, Charles H., Johns Hopkins University
11574 Goss, Raymond W., Carnegie Institute of Technology
11575 Harris, Everett, Pratt Institute

Total 139

OFFICERS of A. I. E. E. 1919-1920

PRESIDENT.

(Term Expires July 31, 1920)

CALVERT TOWNLEY

JUNIOR PAST-PRESIDENTS.

(Term expires July 31, 1920) E. W. RICE, Jr.

(Term expires July 31, 1921) COMFORT A. ADAMS

VICE-PRESIDENTS.

(Terms expire July 31, 1920)

A. M. SCHOEN, L. R. JORGENSEN, C. E. SKINNER, N. A. CARLE, JOHN B. FISKEN, WILLS MACLACHLAN

MANAGERS.

(Terms expire July 31, 1920) CHARLES S. RUFFNER, CHARLES ROBBINS, E. H. MARTINDALE

(Terms Expire July 31, 1921) WALTER A. HALL, WILLIAM A. DEL MAR, WILFRED SYKES

(Terms Expire July 31, 1922) WALTER I. SLICHTER, G. FACCIOLI, FRANK D. NEWBURY

(Terms Expire July 31, 1923) L. E. IMLAY, F. F. FOWLE, L. F. MOREHOUSE

TREASURER **SECRETARY**

(Term expires July 31, 1920)

GEORGE A. HAMILTON F. L. HUTCHINSON

HONORARY SECRETARY RALPH W. POPE

DIRECTOR OF THE LIBRARY HARRISON W. CRAVER

GENERAL COUNSEL

PARKER and AARON,
66 Broad Street, New York.

PAST PRESIDENTS—1884-1919

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
T. Commerford Martin, 1887-8.
Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
Schuyler Skaats Wheeler, 1905-6.
Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Lewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.

*Deceased.

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

Calvert Townley, Chairman, 165 Broadway, New York.
N. A. Carle, W. A. Hall, George A. Hamilton, L. F. Morehouse, W. I. Slichter, C. E. Skinner.

FINANCE COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Hall, L. F. Morehouse.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
L. W. Chubb, E. E. F. Creighton, John H. Finney, L. R. Jorgensen.
Chairman of Committee on Technical Activities, the chairmen of all technical committees, and the chairmen of all Sections.

PUBLICATION COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
N. A. Carle, Wm. A. Del Mar, F. L. Hutchinson, Harold Pender

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
H. N. Latey, J. H. Morecroft, Wm. S. Murray, H. H. Norris, E. M. Sawtelle, Clayton H. Sharp, Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, Murray & Tregurtha Corp., Atlantic, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd, and the chairmen of all Institute Sections *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker, Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose, G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb, A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins, D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 111 Fifth Ave., New York.
F. B. Crocker, Vice-President,
James Burke, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.
Comfort A. Adams, H. W. Fisher, David B. Rushmore, P. G. Agnew, H. M. Hobart, Charles F. Scott, B. A. Behrend, Dugald C. Jackson, Clayton H. Sharp, John J. Carty, B. G. Lamme, C. E. Skinner, L. W. Chubb, W. S. Moody, S. W. Stratton, W. A. Del Mar, A. H. Moore, Elihu Thomson, Gano Dunn, Charles Robbins, R. B. Williamson, Walter C. Fish, E. B. Rosa.

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
J. C. Forsyth, H. B. Gear, H. O. Lacount, Johnston Livingston, M. G. Lloyd, R. W. E. Moore, Henry N. Muller, H. R. Sargent, G. A. Sawin, A. M. Schoen, George F. Sever, H. S. Warren.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, L. B. Stillwell, Schuyler Skaats Wheeler.

BOARD'S COMMITTEE ON TECHNICAL ACTIVITIES

Wilfred Sykes, Chairman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
G. Faccioli, W. I. Slichter.

STANDARDS COMMITTEE

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
E. J. Cheney, Secretary, Public Service Commission, Albany, N. Y.
P. G. Agnew, G. A. Anderegg, Frederick Bedell, L. F. Blume, James Burke, G. A. Burnham, P. H. Chase, H. H. Clark, F. P. Cox, E. B. Craft, W. A. Del Mar, F. M. Farmer, H. W. Fisher, F. C. Hanker, H. M. Hobart, H. H. Humphrey, H. D. James, P. Junkersfeld, A. E. Kennelly, G. L. Knight, R. W. Krass, C. O. Mailloux, C. S. McDowell, W. L. Merrill, Taliaferro Milton, L. F. Morehouse, F. D. Newbury, H. S. Osborne, S. G. Rhodes, Charles Robbins, R. F. Schuchardt, C. E. Skinner, A. B. Smith, John B. Taylor, A. H. Timmerman, W. K. Vanderpoel, R. B. Williamson.

EDISON MEDAL COMMITTEE

(Appointed by the President for terms of five years)

(Term expires July 31, 1920.)
Carl Hering, Chairman, Harris J. Ryan, Robert Lindsay.
(Term expires July 31, 1921.)
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
(Term expires July 31, 1922.)
Comfort A. Adams, L. A. Ferguson, S. W. Stratton.
(Term expires July 31, 1923.)
Frederick Bedell, L. T. Robinson, Calvert Townley.
(Term expires July 31, 1924.)
E. D. Adams, H. H. Barnes, B. G. Lamme.

Elected by the Board of Directors from its own membership for terms of two years.

(Term expires July 31, 1920.)
Charles Robbins, C. E. Skinner, W. I. Slichter.
(Term expires July 31, 1921.)
G. Faccioli, W. A. Hall, Wilfred Sykes.

Ex-Officio

Calvert Townley, President, George A. Hamilton, Treasurer, F. L. Hutchinson, Secretary.

SPECIAL COMMITTEE

COMMITTEE ON DEVELOPMENT

Charles F. Scott, Chairman, Sheffield Scientific School, Yale University, New Haven, Conn.

F. F. Brand, Pittsfield, Mass.
J. C. Clark, San Francisco, Cal.
Ira M. Cushing, Boston, Mass.
W. A. Del Mar, New York, N. Y.
H. W. Eales, St. Louis, Mo.
F. R. Ewart, Toronto, Ont.
W. A. Hall, Atlantic, Mass.
W. F. James, Philadelphia, Pa.
Leslie Killam, Milwaukee, Wis.
P. M. Lincoln, Cleveland, O.
A. S. MacDowell, Rochester, N. Y.
H. T. Plumb, Salt Lake City, Utah.
A. M. Schoen, Atlanta, Ga.
C. H. Schum, Erie, Pa.
Samuel Sheldon, Brooklyn, N. Y.
N. W. Storer, Pittsburgh, Pa.
H. L. Wallau, Cleveland, O.
J. Lloyd Wayne, Indianapolis, Ind.
H. E. Bussey, Atlanta, Ga.
Clem A. Copeland, Los Angeles, Cal.
R. H. Dalgleish, Washington, D. C.
F. G. Dustin, Minneapolis, Minn.
H. S. Evans, Boulder, Colo.
Baxter R. Grier, Gatun, C. Z.
John Harisberger, Seattle, Wash.
V. Karapetoff, Ithaca, N. Y.
J. J. Kline, Fort Wayne, Ind.
Chas. A. Lund, Spokane, Wash.
John C. Parker, Ann Arbor, Mich.
L. T. Robinson, Schenectady, N. Y.
R. F. Schuchardt, Chicago, Ill.
W. D. Scott, Portland, Ore.
G. E. Snider, Toledo, O.
L. E. Underwood, W. Lynn, Mass.
J. W. Watson, Madison, Wis.
J. B. Whitehead, Baltimore, Md.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, 644 Riverside Drive, New York.
H. V. Bozell, John B. Fisken, W. S. Gorsuch,
L. G. Ireland, A. H. Kruesi, J. F. Meyer,
S. G. Rhodes, Allard Smith, E. H. Sniffen,
P. B. Yates.

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.
C. R. Dooley, F. F. Fowle, Charles S. Howe,
C. E. Magnusson, E. B. Merriam, L. F. Morehouse,
G. H. Pfeiff, H. W. Price, R. F. Schuchardt,
W. I. Slichter, William R. Work.

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.
James Burke, Alexander Churchward, A. M. Dudley,
C. E. Eveleth, G. Faccioli, B. G. Lamme,
A. C. Lanier, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.
F. F. Ambuhl, E. R. Berry, Joseph L. Dixon,
I. R. Edmands, L. E. Imlay, F. A. Lidbury,
W. R. Whitney, J. L. Yardley.

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
P. G. Agnew, H. D. Arnold, E. F. Burton,
L. W. Chubb, J. C. Clark, C. P. Eldred,
E. P. Hyde, Chester W. Rice, C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.
P. H. Adams, E. V. Buchanan, H. W. Cope,
Wm. E. Date, James Dixon, A. M. Dudley,
R. H. Goodwillie, H. D. James, W. C. Kalb,
R. H. McLain, E. H. Martindale, A. H. Timmerman,
L. E. Underwood, H. Weichsel, R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 124 E. 15th St., New York.
C. W. Baker, Wm. M. Bradshaw, H. B. Brooks,
F. P. Cox, F. V. Magelhaes, Charles Robbins,
Clayton H. Sharp.

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.
F. B. Crosby, F. D. Egan, Gordon Fox,
Eugene Friedlaender, E. S. Jefferies, W. C. Kennedy,
D. M. Petty, Wm. T. Snyder, Wilfred Sykes,
R. B. Williamson, Fred H. Woodhull, J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. N. Chamberlin, J. R. Cravath, Terrell Croft,
N. S. Dickinson, Bassett Jones, F. D. Newbury,
P. G. Nutting, R. C. Powell, E. B. Rosa,
W. D'A. Ryan, W. M. Skiff, G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.
R. A. Beekman, Eskil Berg, A. R. Cheyney,
Maxwell W. Day, E. G. Gallagher, H. L. Hibbard,
W. F. James, C. A. Jones, C. S. McDowell,
W. F. Meschenmoser, I. H. Osborne, G. A. Pierce, Jr.
J. B. Porter, L. B. Sinclair, H. M. Southgate,
Wilfred Sykes, W. E. Thau, A. E. Waller
F. W. Wood.

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.
R. T. Andrae, F. H. Armstrong, Graham Bright,
L. C. Ilsley, R. L. Kingsland, A. B. Kiser,
Wills Maclachlan, E. B. Woodward.

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.
J. T. Barron, A. E. Bauhan, E. T. Brandon,
H. W. Eales, W. L. R. Emmet, W. S. Gorsuch,
H. P. Liversidge, I. E. Moultrop, Frank D. Newbury,
H. S. Putnam, R. F. Schuchardt, Russell W. Stovel
H. L. Wallau. R. B. Williamson.

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.
G. E. Armstrong, P. H. Chase, W. H. Cole,
E. E. F. Creighton, H. W. Eales, F. C. Hanker,
E. M. Hewlett, F. L. Hunt, P. MacGahan,
D. A. McKenzie, A. A. Meyer, L. C. Nicholson,
N. L. Pollard, F. E. Ricketts, Charles Robbins,
T. C. Taliaferro, H. R. Woodrow.

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 253 Broadway, New York.
O. B. Blackwell R. E. Chetwood E. H. Colpitts
H. W. Drake, W. B. Kouwenhoven, L. F. Morehouse,
R. W. Osborne, W. O. Pennell, L. M. Potts,
S. A. Rhodes, A. B. Smith, D. M. Therrell,
W. H. Winter, D. E. Wiseman.

TRACTION AND TRANSPORTATION

W. S. Murray, Chairman, Room 2800, 165 Broadway, New York.
A. H. Babcock, Reinier Beeuwkes, R. H. Dalgleish,
W. G. Gordon, John Murphy, W. B. Potter,
Ralph H. Rice, Guy A. Richardson, C. S. Ruffner,
N. W. Storer, H. M. Warren.

TRANSMISSION AND DISTRIBUTION

Edward B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
J. E. Woodbridge, Vice-Chairman, 58 Sutter St. San Francisco, Cal.
R. W. Atkinson, A. O. Austin, Wallace S. Clark,
W. H. Cole, A. W. Copley, M. T. Crawford,
E. E. F. Creighton, F. E. Ricketts, D. W. Roper,
C. S. Ruffner, R. F. Schuchardt, A. E. Silver,
W. K. Vanderpoel. C. T. Wilkinson.

INSTITUTE REPRESENTATIVES

ON AMERICAN BUREAU OF WELDING

W. L. Merrill.

ON AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, Wm. S. Murray, F. N. Waterman.

ON AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart. C. E. Skinner.

ON AMERICAN YEAR-BOOK ADVISORY BOARD

Edward Caldwell.

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon. Calvert Townley.

ON COMMISSION OF WASHINGTON AWARD

John Price Jackson, Charles F. Scott.

ON COUNCIL OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

H. H. Humphrey, John B. Taylor.

ON ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle,
Charles S. Ruffner C. E. Skinner.

ON ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

ON FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt L. B. Stillwell.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, Calvert Townley
E. W. Rice, Jr.

ON JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, Samuel Sheldon.

ON JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATOR PINS

J. T. Barron.

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle,
Samuel Sheldon, W. I. Slichter.

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood. Percy H. Thomas.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

ON NAVAL CONSULTING BOARD

Benjamin G. Lamme, Frank J. Sprague.

ON SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

P. G. Agnew, F. Conrad, F. P. Cox, F. C. Holtz, A. E. Kennelly, Farley Osgood, S. G. Rhodes.

ON U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.

Electrical Characteristics of the Suspension Insulator--II.

The Line Insulator at the Higher Voltages

BY F. W. PEEK, Jr.
General Electric Co., Pittsfield, Mass.

IT is the purpose of this paper to review the duties of the line insulator at voltages above 100 kv. and compare them with the duties imposed by the lower voltages. It seems desirable to do this at the present time in order to predict the reliability of future high-voltage lines as compared with those at present in operation, and to point out what changes, if any, are necessary in present practise. The discussion is based in general upon data and operating experiences of many investigations and, in particular, upon extensive investigations made by the author during the last few years. Quite complete data on that phase of the author's investigation dealing with voltage distribution will be given.

Present Status

At the present voltages the problem is primarily a mechanical one. Mechanically, porcelain would never be selected as a line support. It is unreliable in tension, subject to cracking, and if made in large pieces subject to porosity. The greatest care is necessary in manufacture to secure a uniform, tough, non-brittle material, free from porosity. Unfortunately it is the only material that we know of at the present time that will withstand the weather without the carbonization and deterioration of organic compounds under the electrical stress.

Generally after three to five years of more or less successful operation, insulators selected by the most careful electrical tests begin to fail rapidly. There are of course exceptions, but the experience is quite general and most operating companies anticipate breakdown by periodic tests designed to weed out faulty units.

The apparent deterioration of porcelain is generally due to one of the following causes:

1. Gradual mechanical cracking, due to expansion of cement or tight-fitting metal parts, or to internal firing strains or brittle porcelain.

2. Gradual absorption of moisture due to porosity.

The greater part of the trouble has been due to cracking under stresses caused by expansion of cement or of tight-fitting or cemented-in metal parts. Cracking may also be caused by uneven expansion in very thick porcelain parts of different shapes.

The foregoing causes of deterioration are well verified in practise, because the type of insulator in which the porcelain units are strung together by loose fitting metal parts or cables shows no deterioration after ten years or more of service. This was found to be so even when some of the earlier units were made of poor material. The absorption of moisture seems to be due to a considerable extent to breathing. The presence of a damp sponge of cement is thus also undesirable from this standpoint as it keeps moist the air breathed by the porcelain.

The solution of the deterioration problem seems to be to start with a design as free as possible from expansion troubles and the selection of a tough, non-porous porcelain. Years of service have been the best criterion of design. Regarding the selection of material, no present, practical electrical test will anticipate future cracking due to internal strains or brittle porcelain or will indicate porosity in dry porcelain. The desired results can probably best be attained by testing a small percentage of the product to destruction from day to day after the usual electrical and inspection tests have been made, the object being to determine if the product is up to the standard and of uniform quality. This idea is not new, but is used in the manufacture of lamps and in other industries. Electrical, mechanical and porosity uniformity tests are necessary. Extremely accurate tests are not necessary, but it is necessary to have tests that can be quickly made so that any fault can be at once detected and remedied.

In our investigation we made first the electrical tests, followed by mechanical impact tests to destruction. Samples were then taken from the head and thick parts of the units and subjected to a porosity test. In this test the samples were placed in a dye solution under pressure, after which the depth of penetration was noted. The porcelain was placed in three arbitrary mechanical and porosity grades and a graphical chart made indicating the percentage in each

To be presented at the Pacific Coast Convention, A. I. E. E., Portland, Ore., July 21-23, 1920.

grade as shown in Fig. 1. We found this method of great use not only in checking the product and comparing different materials, but also in studying deterioration of insulators in service.

Insulators for the Higher Voltages

The problem of deterioration discussed above is independent of the voltage. Its effect on operation

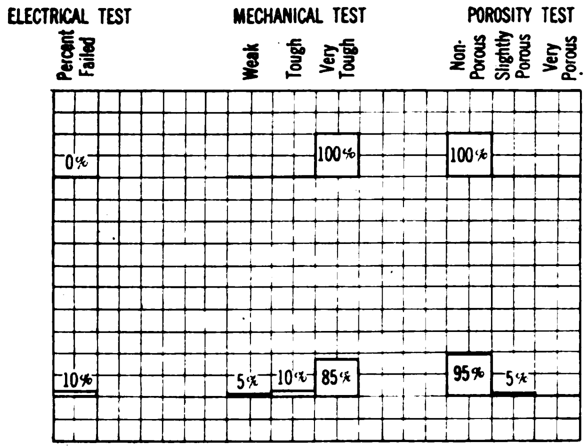

Fig. 1—Sample Sheet Showing Method of Plotting Electrical, Mechanical and Porosity Tests

should be less at the higher voltages because of the greater number of units used in a string. There are, however, certain factors unimportant at the lower voltages, which become of increasing importance as the voltage is increased.

Uneven Voltage Distribution. It has long been known that when insulators are placed in series in a string the

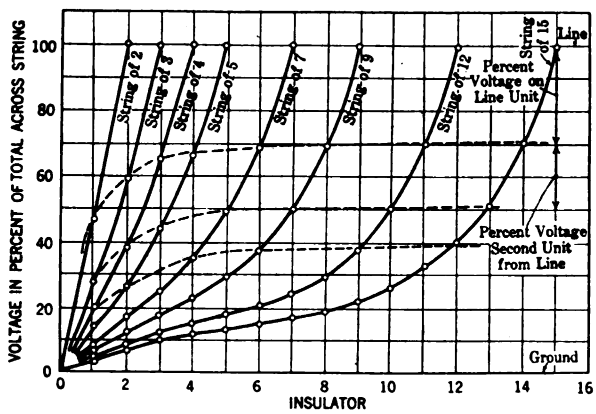

Fig. 2—Typical Voltage Distribution Curves on Strings of Suspension Insulators

arc-over voltage is not the sum of the arc-over voltages of the individual units, but less. This is due to the uneven division of voltage on the different units. A very high percentage is across the unit nearest the line. Typical curves are given in Fig. 2. Fig. 3 shows the percentage of the total voltage across each unit of a string of ten. Even distribution would put 10 per cent on each unit as indicated by the dotted line. It will be noted on examination of Fig. 2 that for strings over five units in length, there is always about 30 per cent of the total voltage across the insulator nearest the line. This will vary from 20 to 30 per cent with different types of insulators and with different hardware on the same type. The importance of a consideration of this

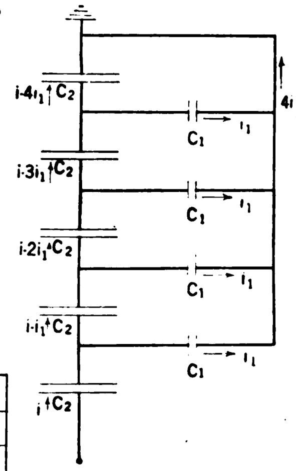

Fig. 4—Cause of Uneven Distribution
The capacities to ground C_1 cause an uneven distribution of current through the insulator capacity C_2.

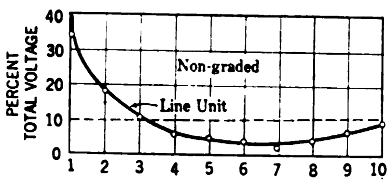

Fig. 3—Voltage Distribution on String of Ten Insulators

factor at the higher voltage is at once seen since the maximum unit stress increases directly with the voltage. At 100 kv. the operating stress on the line unit is 17.4 kv.; at 220 kv. it is 38 kv., which is higher than is desirable.[1] It is desirable to lower the operating stress on the units near the line.

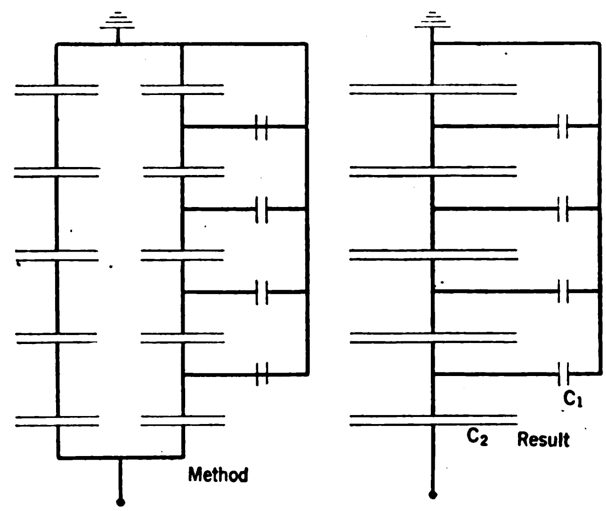

Fig. 5—Grading by Making Internal Capacity of Insulator Units C_2 Large Compared to the Capacity to Ground C_1.

A mathematical analysis of the cause of uneven distribution has already been given.[2] It seems best,

1. $\frac{220}{\sqrt{3}} \times 0.30 = 38$. In the case of a grounded line on a system with isolated neutral this voltage would be $220 \times 0.30 = 66$ kv.

2. Peek, "Electrical Characteristics of the Suspension Insulator—I," A. I. E. E. Transactions 1912, Vol. XXXI, page 907

however, to give here an elementary review of the causes of uneven distribution in order better to discuss the methods of remedying it.

A string of line insulators may be considered as being made up of a number of capacities in series.

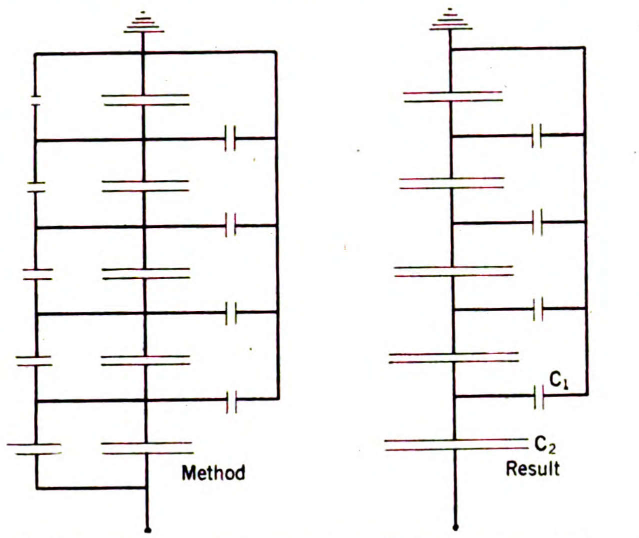

Fig. 6—Grading by Changing the C_2 Capacities in Proportion to Their Respective Currents

There is also capacity from the hardware and fittings of each unit to ground. The capacity may be represented diagramatically by Fig. 4. This arrangement is approximate, but suitable for the purpose of illustration.

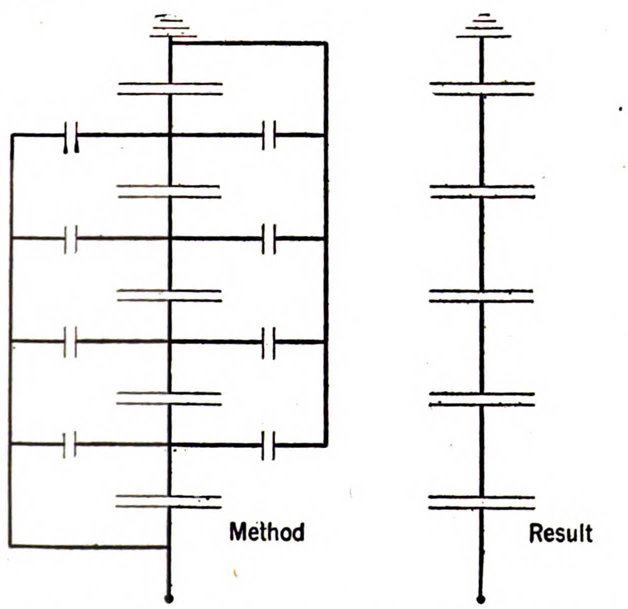

Fig. 7—Grading or Shielding by Eliminating the Effect of the Capacities to Ground

It is at once apparent that the capacity currents cause unequal voltage distribution. If i is the total current through the first insulator, the capacity current through the second one from the line is $i - i_1$ where i_1 is the capacity current to ground; and third from the line $i - 2\,i_1$; the fourth $i - 3\,i_1$, etc. The current and, therefore, the drop is greatest on the line unit; the current decreases successively on each unit from the line by the current to ground of one unit. Correction of voltage distribution may be made by eliminating

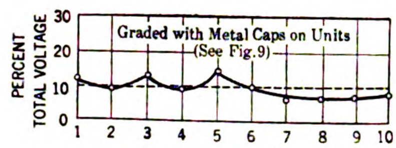

Fig. 8—Voltage Distribution on String of Ten Insulators

the effect of the ground current or the capacities to ground, C_1.

This may be done by any one of the following methods:

1. Increasing all of the C_2 capacities without increasing the C_1 capacities so that the effect of the current to ground is relatively less. See Fig. 5.

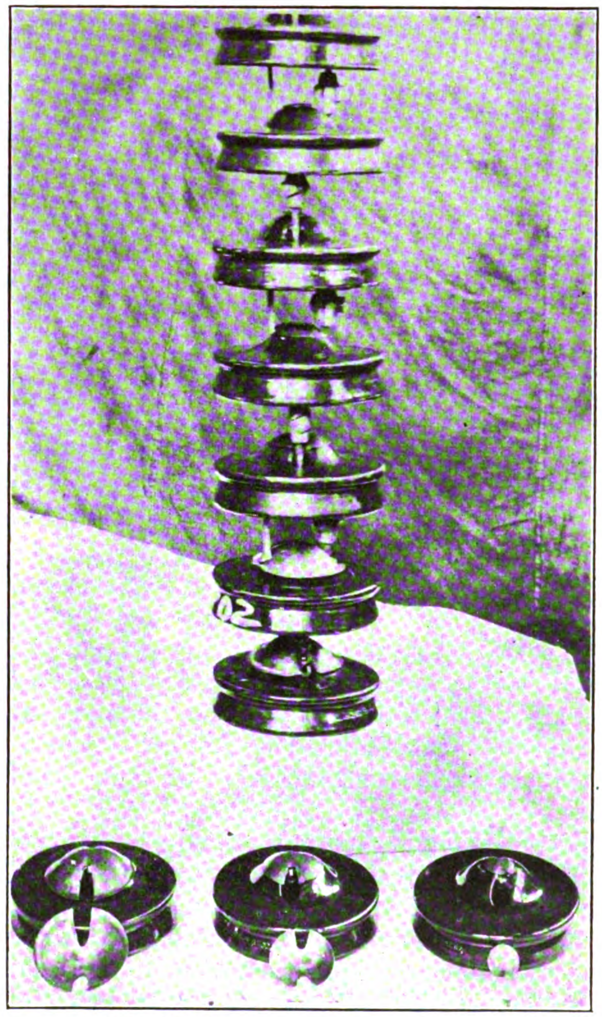

Fig. 9—Grading by Metal Caps

2. Increasing the C_2 capacities of the insulators along the string in proportion to the currents flowing through them. This means highest C_2 capacity on the

line unit, less on the next unit, etc. See Fig. 6—This is generally called grading.

3. Elimination of the ground capacities by means of an antenna shield from the line. See Fig. 7. This may be called shielding.

In order to get appreciable results by method 1, it is necessary to add capacities with solid insulation, or plates in intimate contact with the porcelain. Plates along the string will not help materially, as the percentage increase in the C_2 capacities will generally be smaller than the percentage increase in the C_1 capacities.

Method 2 is practical but it must be accomplished by adding capacities with solid insulations. In practise it means the addition of metal caps or plates in intimate contact with the units, or varying the wall thickness of units, or placing a varying number of units in multiple along the string, or using different sizes of units. Very good results can be obtained by

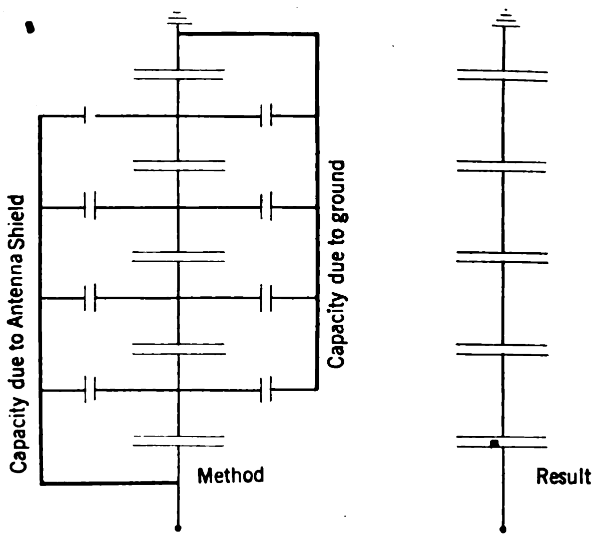

Fig. 10—Shielding by Eliminating the Effect of the Capacity to Ground

this method. Its undesirable feature is that it requires different kinds or sizes of units in the same string. Figs. 8 and 9 show the voltage distribution in a string graded by placing different sizes of caps along the string.

Very good voltage distribution can be easily obtained by method 3. The ground capacities may be thought of as being due to grounded antenna extending along the string. The effect of this antenna may be eliminated by a similar antenna connected to the line and extending along the string as in Fig. 10. In practise the antenna is the very simple shield shown in Fig. 11. The hardware shown in Fig. 11 is not standard but was selected for laboratory purposes to give the worst distribution. The shield readily corrects it. The maximum unit stress would be less on a 220-kv. shielded string than on present non-shielded strings operating sucessfully at 100 kv. and less. The distribution with and without the shield is shown in Fig. 12. A standard hardware giving better distribution with and without the shield is shown in Fig. 13.

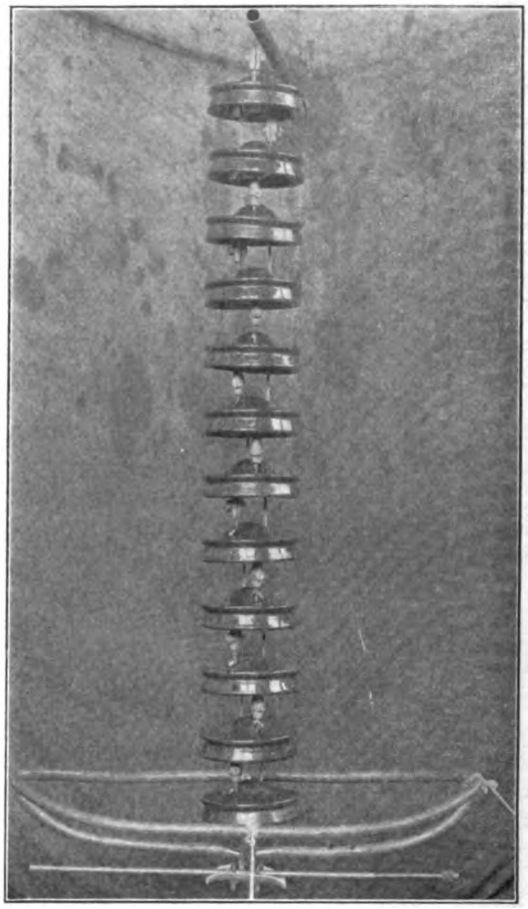

Fig. 11—Antenna Shield for Equalizing Voltage on Insulators
(Laboratory hardware)

This method requires no special units. The antenna has an additional advantage of acting as a corona shield, eliminating corona from the string and tending

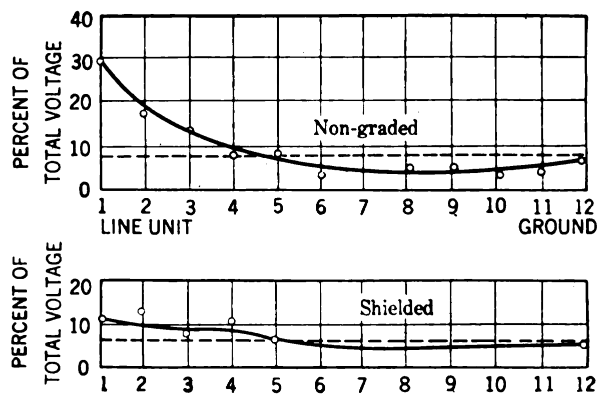

Fig. 12—Voltage Distribution on a String of Twelve Insulators
(See Fig. 11—Laboratory hardware.)

to keep the power arc from the insulators and from burning the conductors. Even if the voltage were evenly distributed a corona eliminating shield would be advisable at the higher voltages.

Heretofore the main argument given for equalizing voltage distribution has been to reduce the string length by increasing the arc-over voltage for a given number of units. It is much more important to reduce the operating stress on the line-end units.

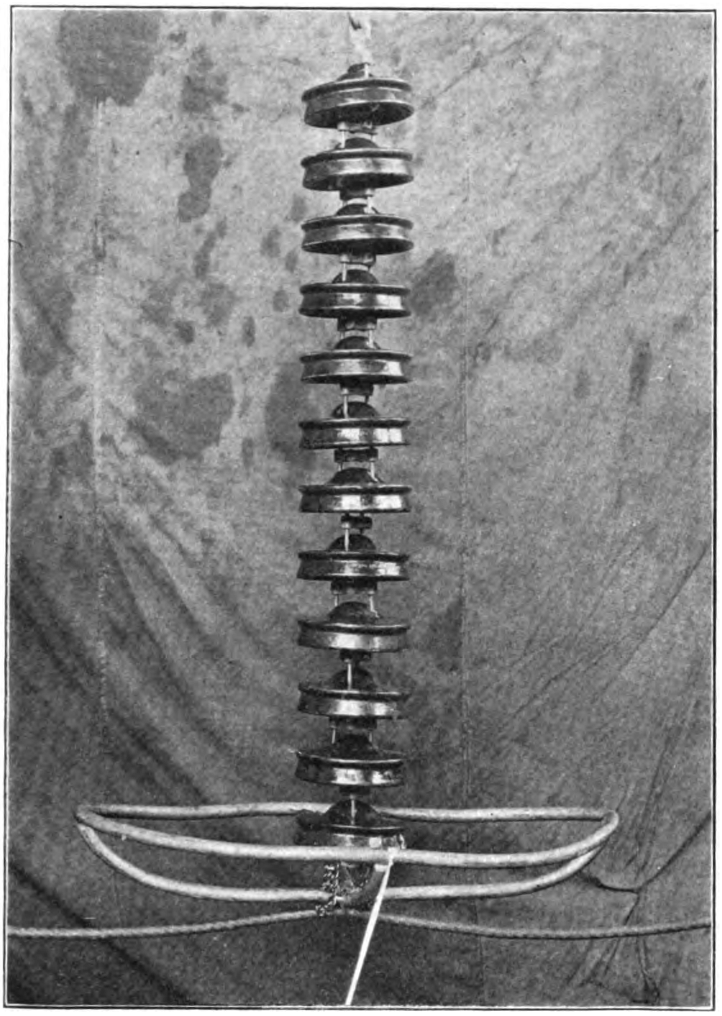

Fig. 13—Antenna Shield
Insulators strung with standard hardware.

With certain types of units the wet arc-over voltage may be higher than the dry arc-over voltage for long strings.[3] This is because rain may assist in grading a badly unbalanced string. As a general rule, a string cannot be very greatly shortened in practise by grading because of the effects of rain, dirt, etc. on the perfectly graded string. There would be little gain in increasing the dry arc-over voltage if the wet arc-over voltage were decreased. Rain would not increase the wet arc-over voltage of a graded string. The wet arc-over voltage would generally be lower if the string length were decreased.

There is an additional reason why grading will generally not make possible an increase in the arc-over voltage or a decrease in the string length. For any unbalanced string there is more or less complete automatic grading as the arc-over voltage is approached. Near arc-over excessive corona forms on the line unit, to a less extent on the next unit, etc. These sheets of corona act as capacity plates and grade the string, thus automatically raising the arc-over voltage. If this were not so, it would be expected that the arc-over voltage for the non-graded string above could for five or more units, never be higher than $\frac{1}{0.30} = 3.3$ times the arc-over voltage of a single unit. As a matter of fact, it is much higher, due to the automatic grading of corona.

The wet and dry arc-over voltage of insulators decreases almost directly with barometric pressure.

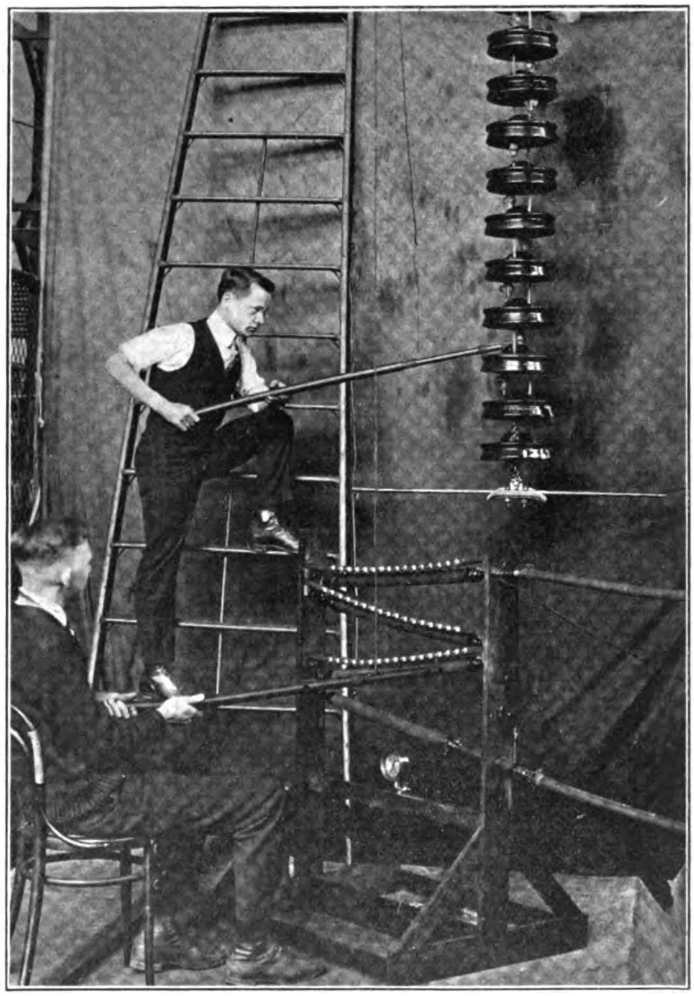

Fig. 14—Method of Making Distribution Measurements

The insulator problem for the higher voltages is therefore more difficult at higher altitudes.

It has been found that the wet lightning arc-over voltage is usually as high as the dry lightning arc-over voltage.[4] The lightning arc-over voltage is, to a great

3. Peek, "Electrical Characteristics of the Suspension Insulator—I." A. I. E. E. Transactions 1912. Vol. XXXI, page 907.

4. Peek, "The Effect of Transient Voltages on Dielectrics," A. I. E. E. Transactions, 1915, vol. XXXLV, page 1857.

extent, a question of string length. If the string length is decreased due to grading the lightning arc-over voltage will also be decreased.

Tests

It may be of interest to describe the method of making tests. A water resistance with 50 taps was

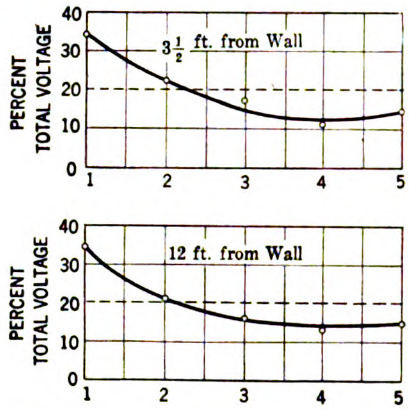

Fig. 15—The Effect of Proximity to Walls
Voltage Distribution on String of Five Insulators.

placed across the line in parallel with the insulators as shown in the illustration, Fig. 14. Each tap had a fixed and known potential above ground, *i. e.*, a given percentage of the applied voltage. Connection was made between the particular unit, the potential of which was being investigated and various taps on the resistance until a tap was found of the same potential. In making this measurement a wire was fastened to a

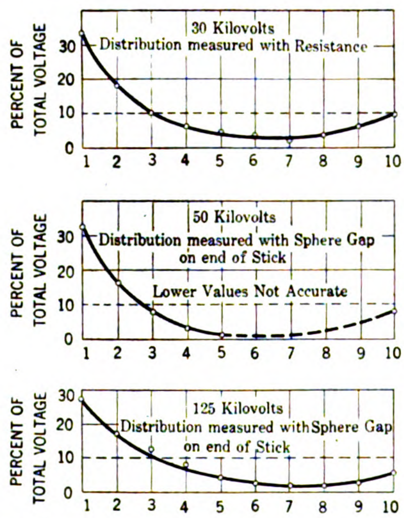

Fig. 16—The Effect of Applied Voltage on the Distribution of a String of Ten

tap and the other end of the wire fastened to a steel point at the end of a fibre rod. When the rod was brought up to the cap a spark would indicate a difference of potential. The connection on the tap was then changed, or the operation was repeated until no spark occurred when the point touched the insulator cap. It was found that the steel point, because of the color of the spark, indicated the smallest difference of potential. In making measurements it is necessary to prevent as far as possible any distortion of the field by the wire and point. A distortion is indicated by different potential readings when measurements are made at

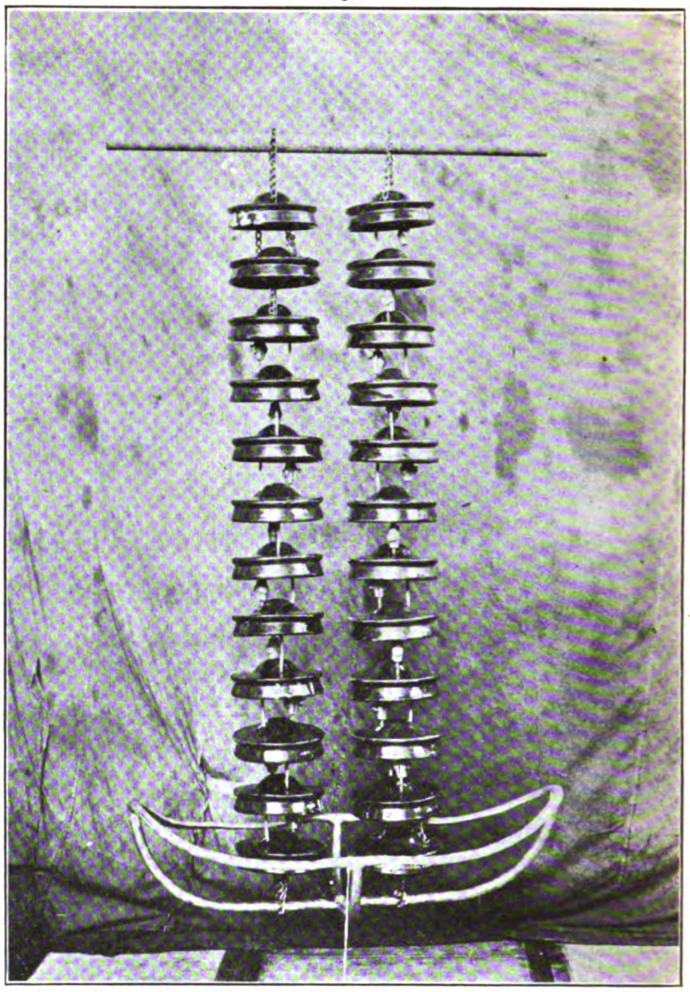

Fig. 17—Antenna Shield on a Double String
Laboratory hardware—See Fig. 18.

different points around the insulator. A stream of water was kept running through the tube in order to keep the temperature constant. Approximate potential read-

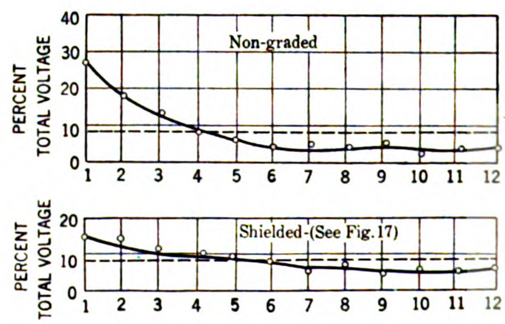

Fig. 18—Voltage Distribution on Two Parallel Strings of Twelve Insulators

ings can be obtained by placing a very small gap shunting a forked stick across the units. This method gives fairly accurate results on the two or three units near the line, but quite inaccurate results on the others.

The effect of proximity to tower, etc., is given in Fig. 15. It will be seen that it is not great. The effect of corona on distribution is not great at the operating voltage. For instance there is very little

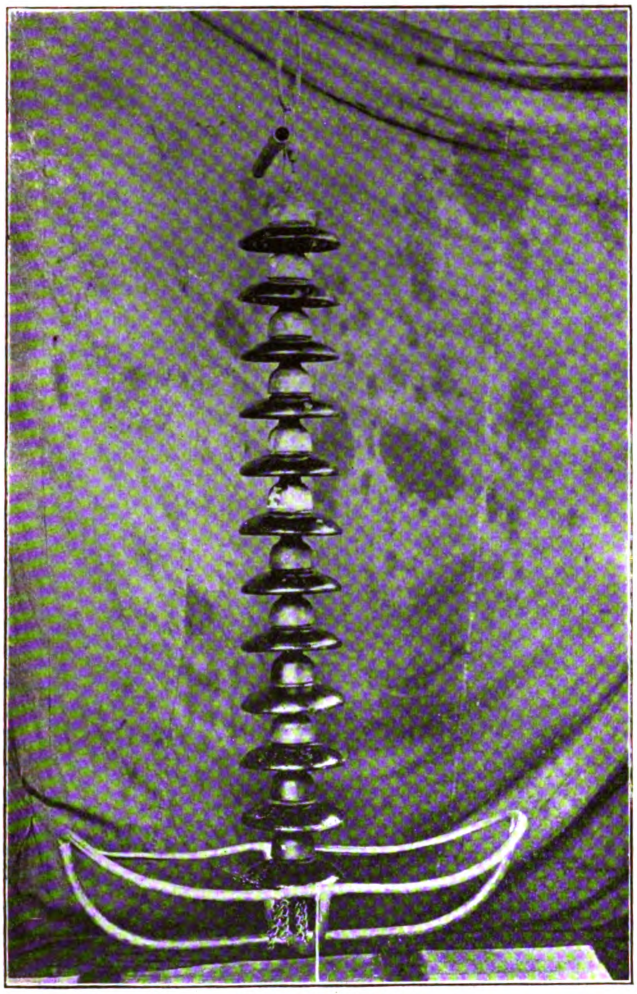

Fig. 19—Antenna Shield
(See Fig. 20.)

difference in the voltage distribution between 30 and 130 kv. 130 kv. is approximately the voltage to neutral of a 220-kv. system. Fig. 16 shows the distribution at 30, 50 and 125 kv. The 50 and 125-kv. curves were made with a spark gap and are accurate for the three units near the line only. Fig. 17 shows the shield used on a double string. The distribution is very good as shown in Fig. 18.

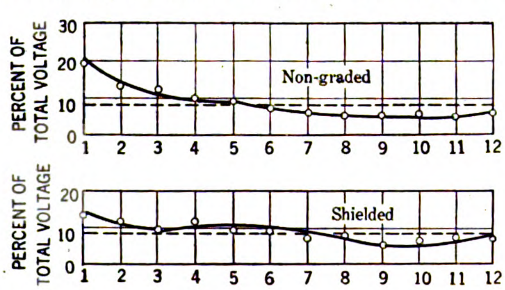

Fig. 20—Voltage Distribution on String of Twelve Insulators
(See Fig. 19.)

Figs. 19 and 20 show the shield and distribution on other types of units. A corona shield is also desirable on this type at 220 kv. The effect on voltage distribution of placing a shielded string in a horizontal position was investigated and found to be negligible. See Fig. 21.

The method of grading shown in Fig. 22 was not found to be very satisfactory.

Fig. 23 shows a form of shield that gave fairly good results.

Distribution tests were made to see if there would be

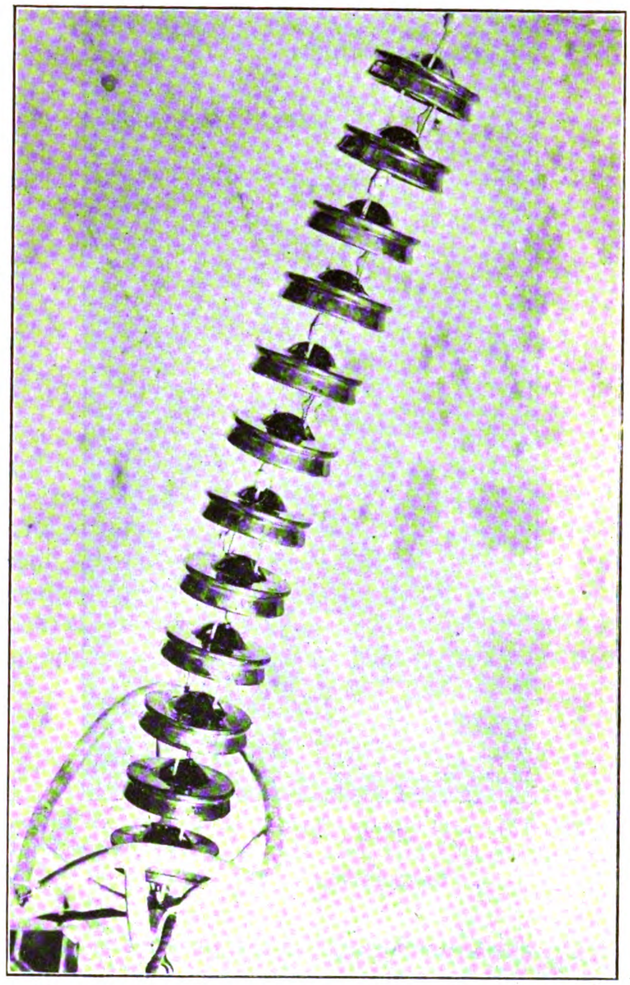

Fig. 21—Antenna Shield for Equalizing Voltage on Insulators

any disturbing effect due to the proximity of other insulator strings as in operation on a three-phase line. There was found to be no appreciable effect.

It is not possible to show all of the various shields tried, but it is believed that the above fairly well covers the field.

Summary

From the above discussion it may be concluded that:

Insulator troubles have been due mainly to cracking caused by expansion of metal parts, cement, etc. and to porosity.

Certain designs with loose-fitting parts have been

free from deterioration. Other designs should be so modified as to relieve them as far as possible from expansion troubles.

Tough non-porous porcelain is desirable.

The old method of basing everything on electrical tests should be abandoned. Severe electrical tests are often harmful. The electrical strength is often secondary to other characteristics. An electrical, mechanical and porosity uniformity test should be established, in which a small percentage of the product is tested to destruction from day to day to ascertain if it is running brittle or porous or is weakened by firing strains.

For the very high voltages that are at present being considered, greater reliability may in many respects be anticipated than for the lower voltage lines. The lightning arc-over voltage and dielectric strength will be relatively higher and induced lightning voltages, sufficient to cause arc-over, will be less than on low-voltage lines. Increasing the number of units in series decreases the probability of complete string failure.

Uneven distribution of voltage on the string becomes more serious at the higher voltages because of the high stress on the unit near the line. For strings of more than four or five units the stress is practically a constant percentage of the operating voltage independent of the string length.

Uneven distribution can be corrected by shielding, shielding prevents excessive corona on the line end units and tends to direct the power arc away from the string. The maximum unit stress on a 220-kv. shield string can be made less than on a 100-kv. non-shielded string.

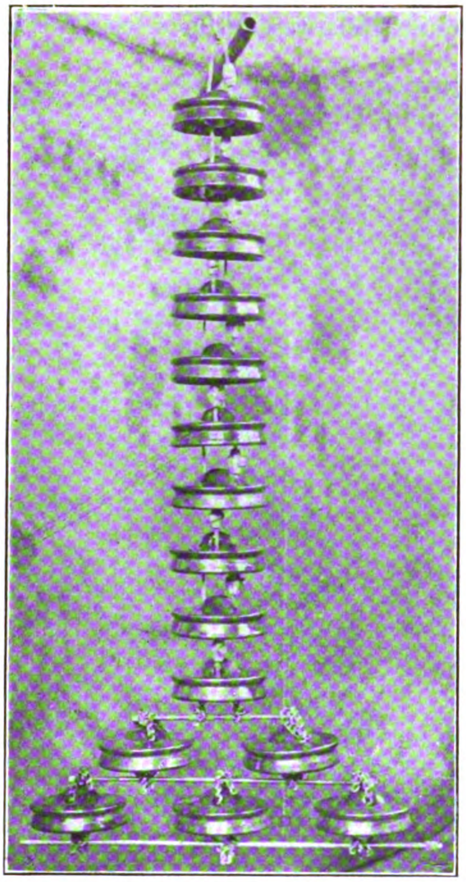

Fig. 22—Two and Three Units in Parallel at Line End of String of 12 Units as a Means of Improving Voltage Distribution on the String

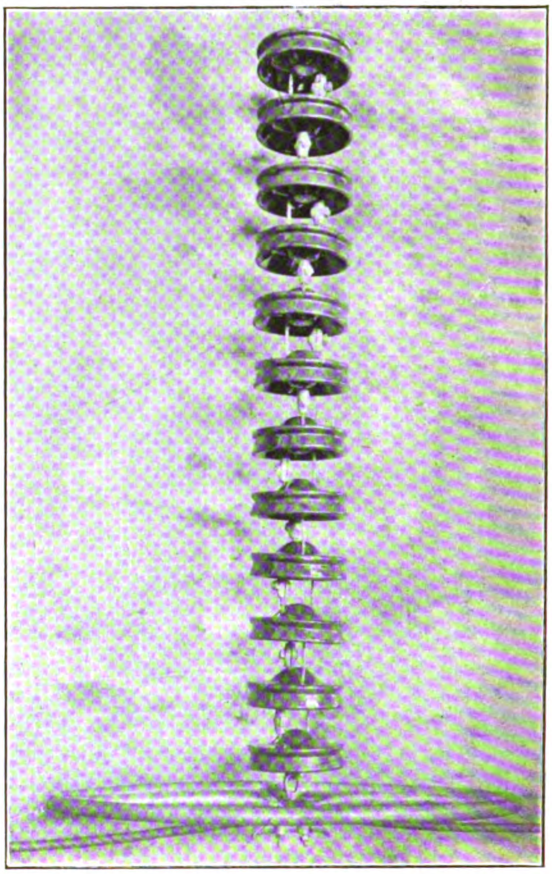

Fig. 23—Antenna Shield for Equalizing Voltage on Insulators

Briefly, outages due to insulator troubles will probably be less frequent at the higher voltages than at present.

The author acknowledges the assistance of Mr. W. L. Lloyd, Jr. in making this investigation.

Unit Voltage Duties in Long Suspension Insulators

BY HARRIS J. RYAN and HENRY H. HENLINE

Both of Leland Stanford Jr. University

POTENTIOMETER measurements* were made of the maximum and average voltage duties occurring in strings made up of *10-inch cap and pin type units* wherein the numbers of the units were varied from 2 to 20. The numbers of units in the string and their corresponding maximum to average voltage duty-ratios thus obtained were used to locate curve II in Fig. 1. The increase in the duty-ratios is small for the shortest string of two units, it accelerates rapidly as the string is lengthened to 7 units and thereafter it remains constant at the rate of 0.09 per unit added from 7 to 20. Such increase is low and accelerating in *short strings* of from 2 to 7 units while it is high and constant in *long strings* of 7 or more units.

In a string of 10-inch *bomb and link type units* the maximum to average voltage unit duty-ratio was found to be 2.5 thus locating approximately the steeper broken line curve I, Fig. 1.

The relation between the unit maximum voltage

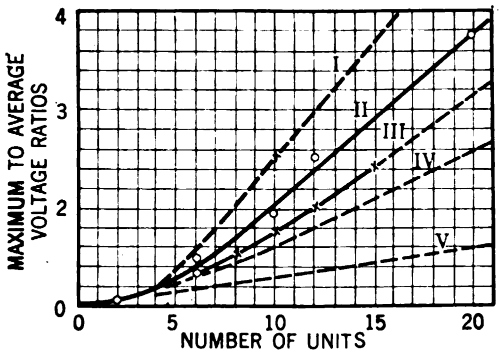

FIG. 1

duty, number of units in the string and three-phase line voltage is given by the equation

$$e_{md} = \frac{d\ e}{1.73\,n}$$

wherein e = three-phase line voltage
e_{md} = maximum voltage unit duty
n = number of units in string
d_r = corresponding duty-ratio taken from sources in Fig. 2.

By means of this equation using values of d_r from curve II, Fig. 1, the maximum voltage unit-duties for corresponding numbers of cap and pin units in the string were determined for line voltages of 110, 150, 175 and 220 kilovolts and employed to locate curves I, II, III, and IV in Fig. 2. Again by using values of d_r for bomb and link units from curve I, Fig. 1, for a line voltage of 150 kilovolts, curve V, Fig. 2, was located.

An inspection of these curves reveals the fact that when the maximum and average voltage unit-duties are assumed to be limited to 18 and 10 kilovolts respectively for cap and pin type units the upper limit of line voltage will be 150 kilovolts and the length

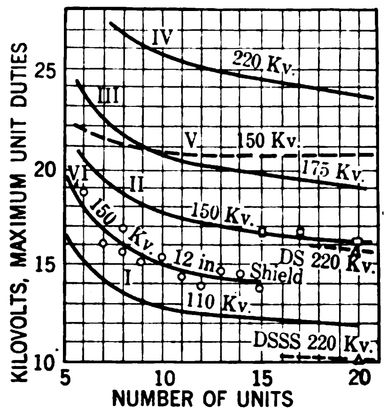

FIG 2

of the string will correspondingly be 9 units. Increasing the number of units from 9 to 20 at this fixed line voltage would lower the maximum voltage unit-duty from 18 to 16 kilovolts, only, permitting a corresponding rise of line voltage in the proportion of 16 to 18, *i. e.*, 11 per cent, or from 150 to 165 kilovolts, an amount that would hardly pay in whole or in part.

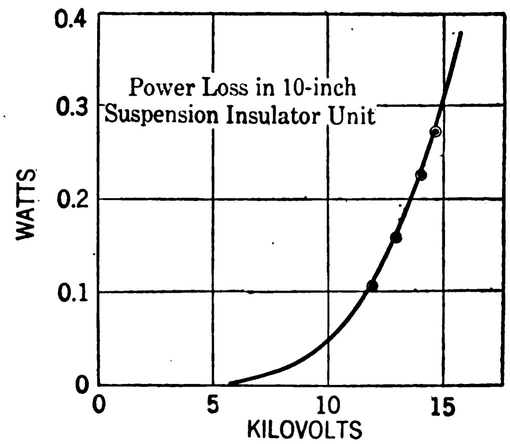

FIG. 3

For a nine-unit string of bomb and link units supporting a 150-kilovolt line the maximum and average voltage unit-duties as obtained from curve V, Fig. 2, are 20.9 and 9.6 kilovolts respectively. While these values are probably permissible, judgment in regard hereto does not appear to be as well defined as for the corresponding values of 18 and 10 assumed for the cap and pin type units.

To be presented at the Pacific Coast Convention, A. I. E. E., Portland, Ore., July 21-23, 1920.

*The High-Voltage Potentiometer by Harris J. Ryan. TRANS. A. I. E. E. Vol. 35, p. 1131, 1916.

The curves reveal further that an increase in string length from 10 to 20 units will cause a corresponding increase in steep wave front flash-over voltage of about 9 per cent for the cap and pin type units and no increase whatever for units of the lower capacitance.

When used to support and insulate a 220-kilovolt line a 13-unit cap and pin string would operate at maximum and average unit voltage duties of 25 and 10 kilovolts respectively. The arrival of loss and corona formation with increase in voltage duty sustained by a 10-inch cap and pin type unit may be noted in the watts-lost-kilovolts curve in Fig. 3. Many engineers feel that a duty of 25 kilovolts for a single 10-inch cap and pin type unit is too high because of corona formation and the injury to hardware and porcelain that may result, likewise because of the low factor of safety against flash-over by cascading. This latter factor is the cause that eliminates the value of a radical departure in the design and construction of the units whereby they would endure satisfactorily much higher maximum voltages. Such practise would tend to increase unduly the maximum to average duty-ratio resulting in low flash-over values. It is generally conceded, therefore, that in the present state of the art some additional means must be employed in suspension insulators for the 220- or 250-kilovolts lines whereby the maximum unit-duties will not be excessive compared with those of present practise.

These maximum unit-duties may be lowered by one or more of the following expedients:

I. Increase in size and capacitance of some or all of the units; grading.

II. Increase in the number of strings in the insulators.

III. Use of static shields.

The first of these, *i. e.*, larger units and grading, is regarded primarily as a manufacturer's problem and will not be taken up in the present paper.

As to what may be accomplished by means of the second and third of these expediencies the following is an illustration: The reductions in maximum unit voltage duty produced in a 20-unit, 10-inch cap and pin type, insulator, (1) by using two strings and (2) by adding static shields made of 2.5 inch well casing 4 feet in diameter, were observed in 1917 by Dr. Leonard F. Fuller and one of the authors in the development of an insulator for the temporary support of a heavy radio aerial operated at 100 undamped wave kilovolts to ground. The results obtained are targeted correspondingly for the 220-kilovolt power line in Fig. 2. The maximum unit voltage duty for the single string was found to be 23.5, for the double string, 15.5 and for the double string with static shields, 10 kilovolts.

Another set of measurements was made by the authors for the specific purpose of illustrating the effect that the use of a small static disk shield would have upon the maximum voltage unit-duty in a single string of cap and pin type units. A dimensioned sketch of the shield used in this case is given in Fig. 4. It is 12 inches in diameter and was developed by Mr. John A. Koontz. A single twenty-unit string without the shield was first set up and the maximum voltage duty carried by the end unit adjacent to the line conductor was determined. The string was then shortened first to 17, and then to 15 units and the corresponding maximum voltage unit-duties also determined. The values thereby obtained were targeted with little squares for a line voltage of 150 kilovolts in Fig. 2, and the values were found to be in agreement with the corresponding values in curve II as calculated from curve II, Fig.1.

The static shield was then mounted and as the string was further shortened, one unit at a time, the corresponding maximum voltage unit-duties were again observed and marked with small circles to locate curve VI, Fig. 2. The same set of values were used to locate the maximum-to-average voltage unit-duty ratio curve III, Fig. 1. For the string of 10 units supporting the 150-kilovolt line, the effect of the presence of this static shield was to lower the maximum voltage unit-duty from 17.5 to 15.0 kilovolts. This corresponds to an allowable upper limit of line voltage

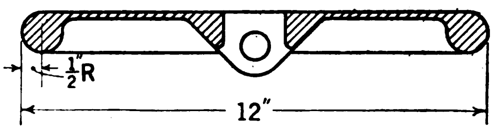

Fig. 4

of $150 \times 17.5 \div 15 = 175$ kilovolts. The essential values for such higher voltage would stand as follows:

No. of units in string,	ten with 12-in. shield.
Line Voltage,	175 kilovolts
Voltage to neutral	101 "
Average voltage unit-duty,	10.1 "
Maximum " "	17.5 "

The corresponding values for the nine-unit insulator without static shield supporting the 150 kilovolt line are:

No. of units in string,	nine without shield.
Line Voltage,	150 kilovolts
Voltage to neutral,	86.6 "
Average voltage unit-duty,	9.6 "
Maximum " " "	18. "

It follows that the *ten* 10-inch cap and pin unit suspension insulator equipped with the 12-inch static shield should serve as satisfactorily for the insulation of the 175-kilovolt line as the corresponding *nine*-unit insulator without shield now serves to insulate the 150-kilovolt line.

From these two illustrations it is seen that by the practicable expediency of increasing the capacitance of the units, of increasing the number of strings of units or of using static shields or by a combination thereof, the maximum voltage unit-duty may be lowered in the long strings (15 units) from 30 to 11 kilovolts for a corresponding average voltage unit-duty of 10

kilovolts. Or more technically, the rate of increase of maximum to average voltage unit-duty ratio with unit increase of string-length can be decreased in long strings by such expedients from 0.2 to 0.02.

Many physical, economic and practical factors enter into the general problem of the extra high-voltage line insulator, *first* as to the make-up and service character of the single unit apart from the insulator as a whole and *second* with respect to the number of units in the insulator string, the number of strings and the form and size of the static shields to be employed. The present units in use are due to a highly organized and experienced cooperation of ceramic, structural and electrical engineers. The integrity of the individual units is a matter of the utmost importance for which, because of the nature of things, the manufacturer must assume responsibility. Not until the manufacturer has amply demonstrated his immediate readiness to deliver by economic quantity production, durable units in which radical changes have been made in design, size and rated mechanical and electrical duty, can the transmission engineer count upon the use of units that may thus differ materially from those in use at present for the support of extra high-voltage (220 kv.) power lines. Such lines will constitute channels through which enormous powers will flow for maintaining the vital industries of regions that are state wide. Avoidable interruptions cannot be tolerated. Uncertain factors in the reliability of these super-power lines will have to be reduced to a minimum. It has taken years to develop for economic quantity production the excellent ten-inch units that are now in extensive and dependable use. Unless the manufacturer can make an ample showing that he is ready to deliver in quantity, designs for extra high-voltage line insulators that have an aggregate superiority in essential qualities, *i. e.* form, durability and cost, the transmission engineer will assuredly undertake the insulation of the extra high-voltage lines with the present units because he knows the essential limits within which he can depend upon them.

The electrical factors in the extra high-voltage insulator that concern the transmission engineer eventually reduce to three fundamentals, viz.: (1) type of unit, (2) maximum and (3) average voltage unit-duties.

The determination of these must rest upon a capable and experienced judgment for any particular requirement. It is the purpose of the authors to deal, only with the quantitative relations that exist between the second and third of such fundamentals, viz.: *the maximum and average voltage unit-duties in line suspension insulators made up of units in common use,* to constitute an aid to the judgment for those who must decide upon the make-up of the insulators to be used for the extra high-voltage lines for which they will be responsible. As yet reliable, analytical methods have not been found for the determination of these maximum to average unit-duty relations when two or more strings and static shields are involved. The relations can only be determined by measurements. Such measurements must be undertaken indoors. It is work that requires large open spaces that are ordinarily difficult to provide. At no time in the present work did the authors have at their disposal as large a space as desired in order to be assured that the presence of walls or nearby laboratory equipment would not affect the value of the results. It was necessary, therefore, to test the integrity of the results by such means as were at hand. In so doing measurements were repeated with the insulators and their high-

voltage line conductors inverted in position with respect to the ground and the potentiometer; by moving them away from nearby walls and model of tower to a position of greater elevation and isolation in the center of the building. When substantially the same results were obtained for all such positions as specified it was concluded that the nearby walls and low elevation of the insulator and high-voltage conductor did not produce results essentially different from those that would be obtained when the insulators would be mounted in the open from regular tower cross-arms.

The results obtained are expressed in the series of Figs. 5 to 21 and the accompanying tables. In the figures, sketches approximately to scale are given of the forms of long insulators of single and double strings with or without static shields. In the tables found below each insulator sketch, the values of the voltage duties are given that are carried by the corresponding units in the string. Such values throughout for all of these cases have been adjusted to a uniform average

unit-duty of 10 kilovolts. The actual voltages applied to the insulators when the measurements were made were always near to the value

$$\text{Kilovolts} = 10n$$

wherein n is the number of units in the insulator string. Thus one may note in the tables the ratios of any actual to average unit voltage duties by dividing the duty as given by 10. For the aid of those who are accustomed to think of the unit-duties in percentages of total applied voltages, parallel columns have been inserted in the tables giving such percentages. It is assumed that these sketches and tables are for the rest self-explanatory and that little further narative in regard to them is necessary.

Figs. 9—10—11—12

From the upper end of the insulator under test metal tubes were mounted horizontally and vertically to the floor so as to affect the electric field about the insulator in the manner that would be done by the upper portion of a particular tower with its cross-arm that will be used in a new project for the support of a 150-kilovolt power line. The upper or cross-arm end of the unit was fixed at about 16 feet from the concrete floor and the vertical central axis of the insulator was about eight feet from the dry brick wall of the laboratory. Exceptions hereto occurred when the insulator was inverted or removed to the center of the laboratory for checking purposes. In the latter case the 20-foot, 1-inch line conductor, maker's standard line clamp and first unit were mounted approximately 16 feet from the floor while the upper grounded end-unit was higher by the length of the string, *i. e.* at a height of from 20 to 25 feet while the central axis of the insulator was remote from the vertical grounding wire about 10 feet and the nearest brick wall about 15 feet. Exception likewise occurred in the single case of the insulator mounted with jumper for strain duty. The strain insulator, one-inch diameter aluminum cable conductor and jumper were mounted in the vertical. The lower end unit was approximately eight feet from the ground. It is believed, however, that the results obtained are near to those that would be obtained correspondingly under actual service conditions.

Unit voltage duty measurements were made with and without a single, circular, 26-inch diameter static shield mounted between the line conductor and the first unit. The results obtained are given in the tables below Fig. 16 which illustrates this laboratory set-up for the study of a long strain insulator with line jumper. From them the lesson is drawn that the jumper is effective in lowering the maximum unit voltage duty thereby offsetting the rise in such duty produced by mounting the line conductor in the axis of the insulator instead of at right angles thereto; and the further lesson that with the aid of a static shield the strain insulator can be adapted for extra high-voltage duty just about as readily as the suspension insulator.

Because of the extra tower clearance required for the long insulators equipped with large guards the idea

naturally developed that perhaps if the "arcing horns" were used and sufficiently extended and maintained in the plane of the conductor they might serve to reduce the maximum unit voltage duties sufficiently without

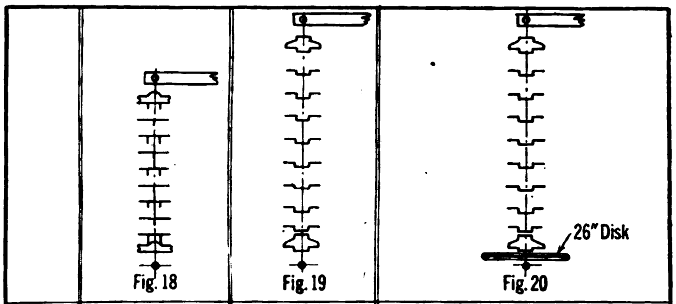
and corresponding percentages of line voltage were measured and determined and tabulated below the figure. The results were rather disappointing. They indicate the superiority of the shield which, to save tower clearance when necessary, may be made elliptical as proposed by Mr. Peek.

To aid one's judgment as to the effect of lessened insulator capacitance and of rain upon the values of the unit voltage duties, duty measurements were made upon three long strings of unit-types as follows: *cap and pin, bomb and link and core and tine, all dry, and*



Strings	Single-10		Single-10		Single-10

FIGS. 18—19—20

core and tine, wet. The results thus obtained are given in the tables below Figs. 18, 19 and 20. The "rain" introduced a strong grading effect, greatly reducing the maximum to average unit voltage duties. Such reduction in this particular case was made to occur from 2.2 to 1.4.

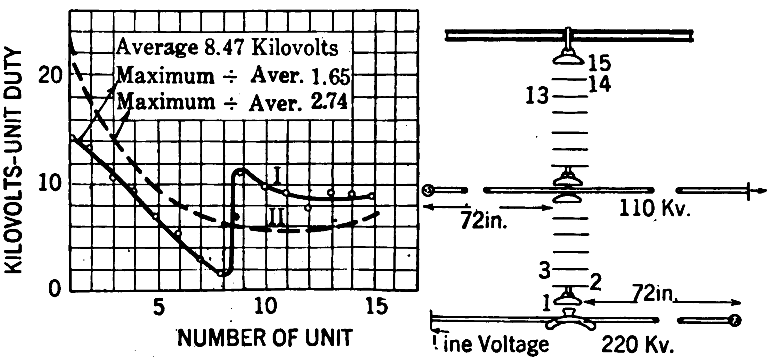

FIG. 21

At the suggestion of one of the engineers who has followed the progress of these studies, the unit voltage duties were determined in an insulator that was subjected to two synchronous in-phase voltages, 63.5 and 127 kilovolts, corresponding to a double line voltage of 110 and 220 kilovolts. The purpose hereof was to obtain knowledge of the corresponding reduction in

unit-duty voltages that result from the use of the associated lines one of which would serve for the flow of trunk line power and the other for power for more local purposes. A single 15-unit cap and pin type string without static shield was arranged to support two 1-inch diameter conductors as illustrated in Fig. 21. The conductor carrying the lower voltage was mounted in the horizontal between the seventh and eighth units. The companion conductor carrying the higher voltage was mounted parallel thereto from the end unit by means of the maker's standard clamp.

With the insulator, conductors and voltages arranged as specified the unit voltages were then measured and the values obtained were used to locate curve 1, Fig. 21. This curve reveals the manner in which the unit voltage duties varied from unit to unit. For comparison the broken-line curve II was located with the corresponding unit voltage duties that were obtained from the same insulator arrangement except that the conductor carrying 110 kilovolts was omitted. It is of interest to note that the ratio of the maximum to average unit-duties was reduced from 2.74 to 1.65 by the presence of the additional conductor carrying one-half main-line voltage.

ACKNOWLEDGMENTS

In closing the authors desire herewith to express their appreciation of the helpful cooperation they have had in the promulgation of these laboratory studies of Messrs. F. G. Baum, S. Barfoed, L. F. Fuller, W. A. Hillebrand, J. P. Jollyman, J. A. Koontz, and J. Mini; for static shields, conductor clamps and other insulator hardware furnished by the Great Western Power Co. and the Pacific Gas and Electric Co.; for insulator units supplied by the Jeffrey-Dewitt Insulator Co., the Ohio Brass Co. and the R. Thomas and Sons Co.; and for assistance in manning the high-voltage potentiometer and preparing figures and tables by F. F. Evenson.

CONCLUSIONS

1. Suspension insulator units in common use can be satisfactorily employed for the make-up of insulators for 250-kilovolt lines.

2. Increase in the number of strings in the suspension insulator will permit the use of a limited increase in line voltage.

3. Static shields in requisite forms will lower maximum unit voltage duties so as to permit the satisfactory insulation of lines for the use of voltages far above 150 kilovolts.

THE M. I. T. COOPERATIVE PLAN A SUCCESS

For the past year an interesting experiment in cooperative engineering education has been conducted by the Massachusetts Institute of Technology and the General Electric Company. While the cooperative scheme in itself is not new, several departures from the usual plan have produced decided results.

The class was limited to thirty students, who were chosen entirely upon the records which they had made in the equivalent of the first two years' work of the Electrical Engineering course at Technology. Included in this group were graduates from Yale, Harvard, Dartmouth, Princeton, the Naval Academy, besides men who had completed their first and second years solely at Technology. The year (12 months) is divided into four three-month periods, the students spending alternately thirteen weeks at the Lynn works of the General Electric Company and eleven weeks at the Institute, followed by a two weeks' vacation. The group at Lynn is housed together in a fine old residence which has been converted into a modern club house. No break is made in the major studies when the students are at Lynn,—courses being conducted at the Works in principles of electrical engineering and in general studies. The progress of the students through the plant is regulated, not by the production needs of the various deprtments, but by the advantage which the experience in each department is to the students.

The result of this year's work has been gratifying to the originators of the plan. Because the students were a selected group, were all taking the same course, and were thrown together intimately at work and at the club house, an intense spirit of loyalty to one another, to the Institute and to the General Electric Company soon became manifest and every man strove to make a reputation for the course. With the students attacking the work in this frame of mind, it is not surprising that their enthusiasm was soon shared by the officials and superintendents of the cooperating company, who are unanimous in stating that the work done in the shops has been preeminently satisfactory. As evidence of its approval of the work, the company has increased the number of men who can be enrolled in this year's class to sixty and has already secured a new club house in order to furnish rooming accommodations for them. The new class which has already nearly completed its quota of members will enter upon the work, July 6.

During the month, the final list of changes proposed for incorporation in the National Electrical Safety Code was sent out by the Bureau of Standards. As soon as comments from interested parties have been received, the new edition of this code will be sent to the printer and it will be available for distribution late in the summer. A similar stage has been reached in the case of the first edition of the National Safety Code for the Protection of the Head and Eyes of Industrial Workers. This code is being prepared in cooperation with an advisory committee of experts in this subject and final changes have been sent to the Committee for consideration. This code also is to be printed in the near future.

Application of Mild and Alloy Steels to High-Tension Suspension Lines

BY L. R. O'NEILL

Cheif Engineer, Maryland Pressed Steel Co., Hagerstown, Md.

A discussion of the application of stamped and pressed steel units of mild, structural and alloy steel to the suspension problem in high-tension transmission.

Factors to be considered in the design of hardware for line construction.

THE tremendously rapid development of long distance transmission of electrical energy at high potential involves most interesting problems in line construction and in insulation. As the structural engineer has been called on to design steel towers to support 500 foot spans and the ceramic engineer to develop porcelain capable of insulation against potentials of 150,000 volts, so the mechanical engineer finds opportunity for the application of his knowledge and training in the development of metallic units involved in the suspension of the line itself. His problem is the development of a suitable means of connection between the tower, the porcelain insulator and the line. The result of his work must insure a mechanical strength as high as the porcelain, the weakest element in the chain, it must be capable of application to the porcelain with due consideration for the wide range of temperature coefficients, and it must finally be capable of adequate protection against atmospheric and gaseous corrosion. Although the hardware element of the line is at first thought a problem of minor importance, it should be given just as careful study as any other element of the line in order to offer the highest possible degree of insurance against interrupted service.

Briefly stated, the hardware problem involves the production of units having a yield point as high as the highest strength of porcelain insulators, the lightest possible weight to insure that strength, a means of application which will offset, as far as may be, the variation in volumetric expansion due to extremes of temperature and finally a construction which will permit the most complete protective measures possible. Although the initial cost of installation generally is a factor of relatively minor importance and subservient to the consideration of longevity and efficiency, that cost is still worth serious consideration as the dollar value changes and all costs advance to hitherto unheard of altitudes.

A study of existing high-tension lines and their history shows that practically nothing has been seriously considered in the design of line hardware other than malleable and grey iron castings and drop forgings of mild steel. The reasons are quite obvious. High tension designing is relatively a new art. The large number of engineers engaged in its pursuit have an almost equally wide range of ideas of design; the rapid development of the art itself has made necessary frequent changes of design. Both castings and forgings are comparatively easy to change, the change involving, as a rule, no great cost. Until 1916 malleable iron castings were relatively inexpensive and the original pattern cost is so small as to add but slightly to the cost of the finished unit. As in many other lines of industry, we find a decided lack of familiarity with the possibilities of working sheet steel into such shapes as come within the field. As an example of this particular point it is only within the last year or so that the manufacture of heavy truck brake drums has been accomplished except by casting them of steel. They are now made by drawing a drum of suitable size and weight from a flat sheet. Such a drum is stronger, more nearly perfect as to shape and requires less machining. Examples such as this might be taken from a dozen different fields. We have all been perhaps somewhat slow to consider or to adopt pressed steel designs, electrical engineers because they did not know just what could be done in that field, the pressed steel engineer himself because it is only within the past few years that he has been able to do it. Beside other limitations it has been difficult for him to obtain from the steel mills a raw material of sufficient homogeneity and uniformity of chemical composition. to permit practical manufacturing operations. Similarly it is only within the last few years that the makers of cutting steel have developed a product suitable for long continued operations of such intricacy and severity as is required.

These conditions are now overcome. We can run 100,000 units through production involving severe drawing and forming operations and have a total loss of less than 1 per cent due either to material or workmanship. Our cutting steels are reliable and relatively inexpensive, the development of the art of high-tension transmission is itself sufficiently settled to permit quantity production, and finally the cost of forgings and castings, because both involve the use of skilled labor, has risen out of all proportion. The field is now open to stampings and it seems proper that we should consider what can be done and how it can be applied to the problem in hand.

In reply to that question, the presse dsteel manufacturers say that practically anything can be made in pressed steel, provided the quantity warrants the ef-

To be presented at the Pacific Coast Convention, A. I. E. E., Portland, Ore., July 21-23, 1920.

fort. The various insulator manufacturers have each their own ideas as to the proper way to apply a porcelain insulator to the line. We have heard the claims made by those who believe in the cap and pin type and in warm opposition thereto the claims of those manufacturers who believe only in the spider type. One engineer asserts that a line clamp should not clamp the line at all but merely support it. The next engineer asserts quite as positively that a line clamp should be capable of resisting at least a 600-pound pull in tension. We are told that a strain clamp should be used by separating the steel core from the body of the cable and we are also told that this should never be done. It is not at all the province of the pressed steel engineer to discuss these points; they belong distinctly to the electrical engineer. It is our function to meet each one on his own ground and out of our own knowledge and experience in working steel offer him a construction and design which will meet his particular requirements. It is as easy or as difficult for us to make a suitable cap as it is to make a suitable spider. We can make a strain yoke out of a single piece of merchant bar 1/4 in. by 2 1/2 in. or out of a flat sheet 1/8 in. thick and perhaps 16 in. square. If our client today requires a line clamp which will solidly clamp the cable with a clip or a bridge plate we can do it. If tomorrow he prefers a clamp which will exert less pressure, that is equally easy or equally difficult. If you will consider the variety of odd shapes and strange sizes now being made in heavy presses you will be amazed. Axle housings, engine oil pans, railway ties, car seat pedestals, wire wheel hubs, clutch housings, interior wiring devices such as junction boxes, switch housings and bosses, all these are live testimony to the possibilities of the trade. Whether the design required metal in thousandths of an inch or quarter of an inch one has but to design suitable tools and feed the steel into a press. If cross-sections of varying thickness are required, they can be obtained by folding the metal on itself or by varying the thickness in the course of the drawing operation. If the desired shape cannot readily be formed from a single sheet, welding, either electric or touch is available and a perfectly reliable unit results. The uniformity of the product greatly reduces and usually eliminates machining and grinding operations; the unit is ready for use when it comes from the press. Of course such designs require careful study and a considerable knowledge not only of the art of working sheet steel but involve at least some degree of familiarity with problems of the electrical engineer.

Having in mind that we are presenting something relatively new, we ask that you consider what advantages pressed steel offers over malleable castings and forgings. Pressed steel units are uniform. You may pick up half a dozen units from a pile and caliper them, not with a scale but with a micrometer, and you will find variations which are to be measured in only a few thousandths of an inch. Holds line up perfectly. Caps are of absolutely uniform inside and outside diameters within a few thousandths of an inch. There is a corresponding uniformity of thickness and weight as well as finish. Uniformity such as this makes for easy handling and less expensive assembly with a complete absence of rectifying operations and fittings. Neither malleable, castings nor forgings are capable of such uniformity. The very nature of a casting involves considerable variation as to size and weight and one has only to go into an insulating plant to see castings being straightened with a hammer and filed or ground before they can be used. There is always a great variation in forgings and the flash or fins left by the dies is a variable factor, frequently involving more or less work before the unit can be used.

The physical strength of the unit is assured. The malleable iron casting is made by pouring molten iron into a mould, cooling and annealing in a furnace. You insulator manufacturers know how difficult it is to keep a furnace temperature absolutely uniform and to be sure that every cubic foot of the interior of the furnace is at the same temperature as every other cubic foot. If these conditions are not at least approximated in annealing castings, there is a wide range of temper and consequently of strength. Forgings are subject to similar possibilities of defect. If steel is handled under a drop hammer at too low a temperature, crystallization begins and the unit lacks the strength it should have. All pressed steel units are free from such defects and require only the most casual inspection and test. The steel itself is made in either an open hearth furnace, a Bessemer converter, a crucible or possibly an electric furnace. It is poured into ingots and from each heat a sample is taken which is submitted to physical and chemical analyses to insure that the ingot itself is of the desired quality. The ingot is rolled into the desired shape and inherent defects in the steel show almost automatically in the process of rolling. When the steel reaches our hands its percentage of imperfection is very low indeed. In the course of making a particular unit the steel sheet is blanked, drawn, formed and stamped, each of these operations requiring the application of such loads as invariably bring out any imperfections which still remain. In the making of a spider for example, the blank is cut out of the steel with its six or eight legs in a plane. Some 280 tons are required to effect this blanking and under such pressure any defects in the steel become immediately visible. Following the blanking, the spider is formed up into its cup shape by pushing it through a cylindrical die, involving a pressure of perhaps 175 tons. The steel is here given a relatively sharp right angle bend and if there be a pipe or seam in the sheet it is shown at once. In like manner the various severe operations which are performed cold on sheet steel to effect the desired results are such as to bring out any imperfections which the

steel may have. If malleable iron castings are to be used they must be designed with a very high safety factor and even then the production manager will have his troubles. The percentage of rejections on malleable iron castings are very much higher than in any pressed steel construction and in order to find out these rejections more or less elaborate testing facilities must be used on every piece. We do not need such tests with steel units. Forgings are less open to the criticism here applied and may properly be considered quite as satisfactory as pressed steel units in this connection.

The problem of protection against the corrosive action of the atmosphere and such influences as exhaust gases from locomotives and other sources has been given increasingly greater consideration during the past two or three years. Pressed steel units lend themselves better than any others to adequate protection by galvanizing, lead coating or enameling. They are clean and clear cut. Malleable castings show a certain inevitable percentage of units in which minute particles of slag and other impurities are imprisoned in the surface. Zinc applied by either the galvanizing or sherrardizing process to the castings cannot completely cover these tiny particles, an oasis is formed and in due time the salt air works its way along this little pinnacle of slag and underneath the zinc coating and our old enemy rust commences its work. Steel has no such surface imperfections and its protective coating is complete and impenetrable.

There is an unlimited supply of raw material of wide range. Units such as we are interested in can be made of anything from tank steel having an ultimate tensile strength of from forty to fifty thousand pounds to the square inch through the various grades of mild and structural steel having an ultimate tensile strength of approximately 75,000 pounds to the square inch up to alloy steels which include Chromium, Molybdenum and nickel which, with suitable heat treatment, will achieve an ultimate tensile strength of 180,000 pounds to the square inch. Malleable iron castings are limited to a narrow range of strength which may not extend beyond 44 or 45,000 pounds to the square inch. The relation of the yielding point to the ultimate tensile strength in steel may be quite definitely controlled within a considerable range and in the case of alloy steels, by proper heat treatment, may be brought up to 80 per cent of the ultimate strength insuring the highest possible usable strength with the least possible weight. Such a range of material from which to choose for our production certainly demands serious consideration.

The readiness with which the raw material itself can be secured is also a considerable factor. Go, if you will, to a malleable foundry and ask for 500 tons of malleable castings and at the same time ask a steel mill for 500 tons of sheet and learn for yourself at first hand which is the easier to obtain.

Both malleable iron castings and drop forgings involve of necessity the use of skilled labor. The enormous increase in the use of malleable castings and drop forgings in the automobile industry has resulted in demands on the foundries and forges which they cannot possibly fill, partly because of lack of equipment and partly because of the shortage of skilled labor. One cannot make a moulder or a hammerman overnight. If pressed steel constructions are used the employment of a relatively small number of very highly skilled mechanics is necessary only for the making of tools. The actual production of the unit itself is in the hands of unskilled labor which not only works at a relatively low wage but can be trained in two or three days to a high degree of efficiency. As in the production of the steel itself the machine does the work.

Quick deliveries are possible in steel. The ready availability of raw material and the relatively short time required to make tools insures an early start on the work. Most of the units which are likely to be used in this field can be turned out at the rate of at least from three to four hundred per hour and can be finished within the time required to put them through the various operations. Malleable iron castings must be annealed and the annealing process takes from three to seven weeks. The first piece must perforce wait on the necessary pattern equipment. Drop forgings cannot be handled so rapidly. The tools take practically as long to make as tools for sheet steel construction and it is never quite so easy to get exactly the right sizes of steel required to make a forging as it is to cut up a sheet of steel to the dimensions suitable for blanking. When a contract is finally let for the construction of a line, someone invariably wants hardware about two or three days later. It is certainly worth while to know that pressed steel units can be turned out in quantities in generally less time than any other construction.

Finally, we have to consider the question of cost. One is no longer shocked at being asked to pay from 12 to 18 cents per pound for malleable iron castings and prices as high as 24 cents per pound are not exactly new. The initial cost is not the only cost because extra fitting and inspections are required. Drop forgings at 12 cents per pound and higher are not uncommon. In contrast with these prices the raw material used for pressed steel units costs from 7 to 12 cents per pound for the steel best suited to this work, although alloy steels which are eminently desirable for certain conditions of extreme load may cost as much as 80 cents per pound. Very little calculation is required to show that the net cost is somewhat lower when operations which rarely number more than ten are performed at a rate of from three to five hundred per hour. The cost of tools which must naturally be amortized over the entire production is a factor of considerable importance. Generally speaking, the larger the unit by weight the lower the price because the labor

element of the cost remains practically the same, and it is probably safe to say that when pressed steel designs can be offered in lieu of castings or forgings the price will be somewhat lower and as a result of our experience there seems little reason to doubt that their efficiency is considerably higher.

In conclusion the engineers who represent the various pressed steel manufacturers are ready and willing to handle such problems as you may offer them, to apply the fruit of their experience in other lines and to work in close cooperation with you in the development of the high-tension lines.

Bridge Methods for Alternating-Current Measurements

BY D. I. CONE
Pacific Telephone & Telegraph Company, San Francisco, Cal.

THE extension of the field of application of electric energy to human service requires more and more of measurements of electrical quantities, of varying grades of precision. Very prominent in the history of electrical measurements is the so-called "bridge" method, the fundamental principle of which is the equalizing of the potentials of two chosen points in a network of electric circuits. The original application of this principle was made by S. H. Christie in 1833 to the measurement of resistance to direct current in the arrangement long familiarly known as the Wheatstone Bridge. Numerous forms of Wheatstone Bridge for direct-current measurement have been developed. The conditions for its use have been investigated thoroughly and are well-known.

Of later development and less known and understood are the applications of the bridge principle to measuring impedances of alternating-current circuits. However, the knowledge of the Wheatstone Bridge as used with direct current can immediately be made use of for alternating-current testing by applying the principle stated by Kennelly in the following words.[1]

> It is however, a seemingly universal and a wonderful law, that all the numerical formulas and rules of quantitative behavior for continuous-current circuits, or conductors, are exactly the same for single-frequency alternating-current circuits or conductors, in respect to potentials and currents as also (with minor reservations) to power and energy if these formulas and rules are interpreted as relating to complex numbers.

The purpose of this paper is to present a resumé of simple methods of utilizing "bridge" networks in alternating-current measurements of impedances and their components of effective resistance, self and mutual inductance and capacitance, and in frequency measurement.

A great variety of arrangements have been described by numerous writers. It is not attempted to include all of these, but to present such a group as will give latitude of choice to suit the apparatus that is available, or permit the use of several methods to check against each other. By the methods shown approximate measurements over wide ranges of values can be made with very simple apparatus. It is hoped that others will add from their experience to the value of the collection.

Before taking up the various practical forms of bridge network, it will be helpful to consider the conditions for balance and other characteristics of a "Wheatstone bridge" wherein the four resistances are replaced by impedances. Thus generalizing the Wheatstone bridge network and utilizing the ordinary formulas in accordance with the principle quoted from Kennelly's statement given above, the relations shown

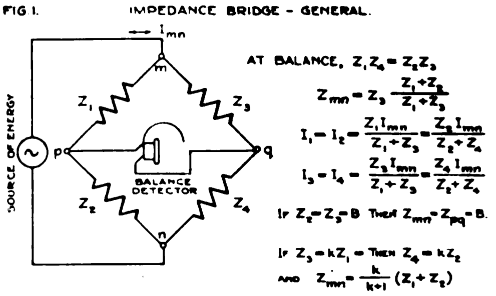

FIG. 1

in Fig. 1 are determined. In place of resistance is written the impedance.

$$Z = \sqrt{R^2 + X^2} \,/\theta = R + jX$$

Where R = effective resistance

X = effective reactance (+ if inductive, − capacitive)

$$\theta = \tan^{-1} \frac{X}{R}$$

The standard rules for combining complex numbers must of course be observed in using the formulas. Besides the formula connecting the several impedances at balance, the impedance of the whole bridge between the corners m and n is given, also the division of current among the branches. These are useful when it is necessary to determine the current input to the circuit whose impedance is being measured. It is of interest that when two opposite impedances of the network, as Z_2 and Z_2 or Z_1 and Z_4, are equal, the impedances Z_{mn} and Z_{pq} are alike equal to that same value.

Interchanging the energy source and balance detector connections, (energizing at p, q, and equating the

1. Kennelly—Hyperbolic Functions Applied to Electrical Engineering.

potentials of m and n for balance) the same impedance relation prevails for balance, but the impedance, Z_{pq}, is in general different from Z_{mn}. Thus,

$$\frac{Z_{pq}}{Z_{mn}} = \frac{(Z_1 + Z_3)\,(Z_2 + Z_4)}{(Z_1 + Z_2)\,(Z_3 + Z_4)}$$

$$= \frac{Z_2\,(Z_1 + Z_3)^2}{Z_3\,(Z_1 + Z_2)^2}$$

When $$Z_3 = kZ_1$$

$$\frac{Z_{pq}}{Z_{mn}} = \frac{Z_1 Z_2}{(Z_1 + Z_2)^2}\;\frac{(I + k)^2}{k}$$

The arrangement to be used in practise to secure greatest sensitivity, for a given departure from the balanced condition, depends on the impedances of the branches, including the balance detector and energy source, and on the kind of circuit being measured. For example, where a telephone receiver is used, the disturbing extraneous noises may be less with one connection than the other. If the balance detector has higher impedance than the energy source, it should

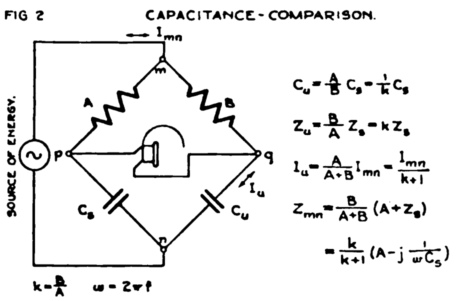

FIG. 2

be connected between the two opposite points of the network having the higher impedance.

Specific applications of these general formulas, and examples, will be given below. It is to be observed that the bridge methods here described provide for comparisons among resistances, inductances, capacitances, etc. and not for absolute measurements of any of them in terms of the fundamental units.

Fig. 2 shows the arrangement (due to De Sauty) for comparison of two capacitances. For the standard capacitance a variable condenser may be used, or with a fixed condenser the ratio of A to B can be adjusted, as by having A and B in the form of a slide wire. Variable resistance boxes, such as are found in Wheatstone bridges are also convenient for A and B. It is to be noted that the ratio $\frac{A}{B}$, the multiplier for obtaining C_u, is the reciprocal of the factor $\frac{B}{A}$ for Z_u and R_u since the impedance of a pure condenser is inversely proportional to its capacitance. C_s should be as nearly as convenient of the same magnitude as C_u. The method allows of precise adjustment for balance only when the two capacitances have very closely the same power factor, as for example the case of comparing good mica condensers.

Where the power factors of the standard and unknown condensers are different, and in general for measurement of capacitive impedances, including both resistance and capacitive reactance components, the form shown in Fig. 3 (due to Wien) can be used. A variable resistance r is arranged so it can be made part of either R_s, the effective resistance of the "standard" arm, or R_u, the effective resistance of the "un-

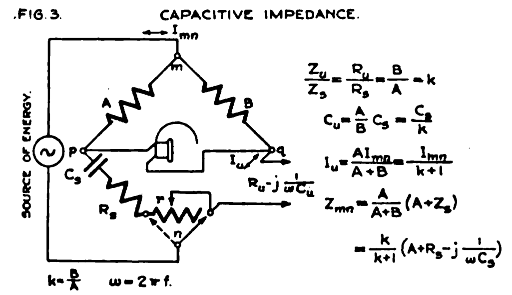

FIG. 3

known" arm. If the standard condenser C_s has a very small energy loss or effective resistance component, as in the case of a good mica condenser or an air condenser, R_s will be practically identical with its component r, external to the condenser. Mica condensers have phase angles of from one or two minutes up to six or seven minutes or more, depending on their quality. At 1000 cycles per second and with a 0.1 microfarad condenser having a phase angle of five minutes the reactance is $\frac{10^6}{2\,\pi\,1000 \times 0.1}$ or 1592

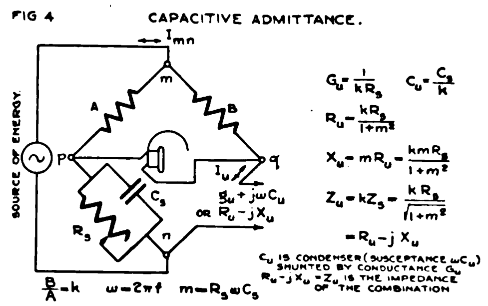

FIG. 4

ohms. The resistance is then 1592 sin 5 minutes or 2.3 ohms. For ordinary work, therefore, the effective resistance of a mica condenser can be neglected. With paper condensers much greater effective resistances are encountered.

The arrangement of Fig. 4, where the standard resistance and condenser are in parallel, may be designated as an admittance bridge, since it is adapted to determine more directly conductance $\left(g_u = \frac{A}{B\,R_s}\right)$, sus-

ceptance $\left(b_u = \omega C_u = \dfrac{A}{B} \omega C_s \right)$ and admittance $\left(Y_u = \dfrac{A}{B} Y_s \right)$ than the form previously described. Impedances may also be calculated from the values of R_s, C_s, A, B, and frequency f.

Whether the method of Fig. 3 or that of Fig. 4 shall be used may depend on the range of the apparatus available. As an example, let $B = 2A$, and consider the necessary values of R_s and C_s for the case where Z_u is a resistance of 1378 ohms (R_u) in series with a condenser of 0.362 microfarads (C_u). Then with the arrangement of Fig. 3 (R_s and C_s in series) the setting of R_s is 689 ohms and C_s is 0.724 microfarad for all frequencies for which the given values of R_u and C_u hold true. With the arrangement of Fig. 4 (R_s and C_s in parallel) $R_s = 800$ ohms and $C_s = 0.100$ microfarad at $\omega = 5000$ ($f = 796$ cycles per second). For other frequencies the Fig. 4 bridge values would differ.

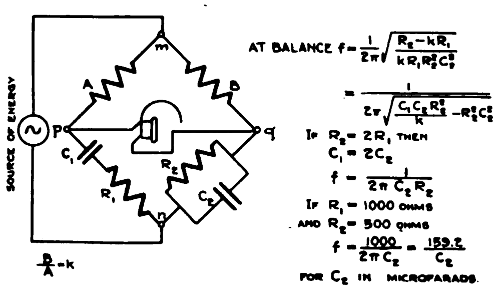

FIG. 5

The above example illustrates the fact that the shunting of a condenser by a resistance affords a means of increasing its effective capacitance. This is shown more fully in the curves of Fig. 18 for a capacitance $C_2 = 0.1$ microfarad shunted by a resistance R_2 varied over a wide range, the frequency chosen being $\omega = 2\pi f = 5000$. The effective capacitance of the combination is C_1, and the resistance, R_1.

A method is thus afforded for using a fixed condenser as C_s for measurements with the Fig. 4 bridge. On account of the variations of the effective resistance, (see R_1 of Fig. 18), additional series resistance (like r in Fig. 3 and 6) is necessary to obtain balance.

The effective inductance of a fixed inductance coil can be varied in like fashion to the condenser just described. Referring to the case of Fig. 18, for the chosen frequency, a self-inductance of 0.4 henry (of low resistance) shunted by resistance R_2, exhibits the same effective reactance (X_1) and resistance (R_1) as the condenser C_2 of 0.1 microfarad. The effective inductance L_1 is always *less than* L_2.

A bridge method of determining frequency, using resistance and capacitance only, connected in series on one side and in parallel on the other, is shown in Fig. 5. The formula for the general case is rather complicated, but by choosing the shunt resistance R_2 equal to twice the series resistance R_1, the condition for balance is $C_1 = 2C_2$ and the frequency is

$$f = \frac{1}{2\pi C_2 R_2}.$$

By setting $R = 1000$ ohms

$$f = \frac{1000}{2\pi C_2},$$

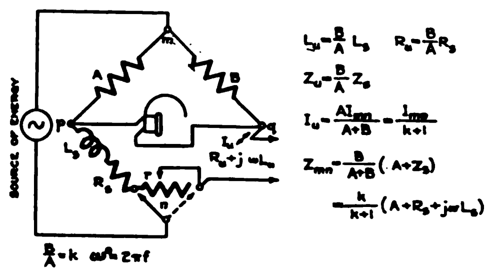

FIG. 6

C being expressed in microfarads. A corresponding method might be used employing inductances of low effective resistance.

A bridge for the direct comparison of inductances and measurement of inductive impedances (due to Maxwell) is shown in Fig. 6. As in the case of the bridges already described, a slide wire may be used to form A and B arms, with a fixed inductance L_s. A shunted inductance can also be used for values below the range of L_s. To measure inductances higher than

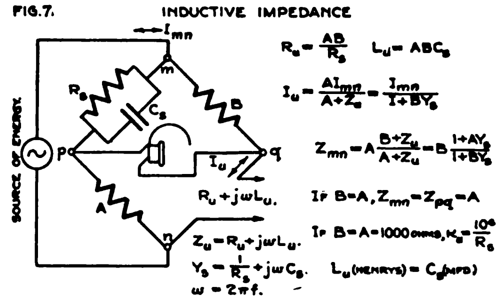

FIG. 7

$k L_s$, a condenser may be connected in series with Z_u. A condenser of capacitance C' can be considered as a negative inductance of size $L' = \dfrac{1}{\omega^2} C'$. The inductance L_u will than be $k L_s + L'$.

Methods will next be described for comparing self-inductance with capacitance, or stated more generally, of determining inductive impedances by comparison with capacitive impedances, or vice versa.

Fig. 7 shows an arrangement (due to Maxwell) much used for determining inductive impedance in terms of a resistance and condenser. It can, of course

be used also for the converse process. A series resistance and condenser can be used in place of R_s and C_s, but the formulas are less simple. This form is not shown. Especially simple calculations are afforded for the Fig. 7 bridge by making $A\ B$ (each in ohms) equal one million. Ordinarily R_s and C_s are the variable elements, but balance is obtainable by varying others such as A, B or L_u. A vector diagram of currents and potential differences of this bridge is shown in Fig. 17, which gives data of a numerical example.

In Fig. 8 is presented a modification of the bridge just described, known as the Anderson bridge. A resistance r is connected between condenser C_s and corner p, and the detector is connected to the junction of r and C_s. By varying r, a fixed condenser C_s can be used for inductive impedance measurements over a wide range. Where r is large it has been found advantageous to interchange the energy source and the detector.

Fig. 9 presents a bridge set-up suitable for making measurements in quick succession of capacitive and inductive impedances. For measuring capacitive

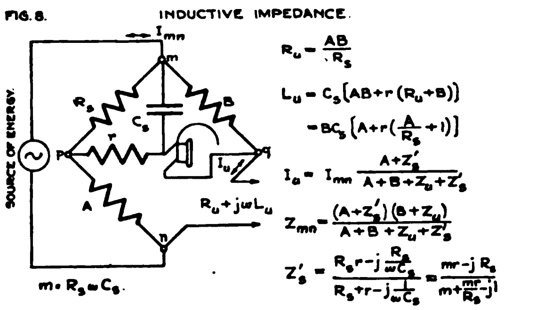

Fig. 8

impedances, it is the same arrangement as that presented in Fig. 4. By switching the condenser C_s so that it is connected from n to q, instead of to p, balance is obtained for an inductive impedance Z_u. The same formulas apply in each case, changing sign of the reactance X_u, when ratio arms A and B are equal. This bridge can also be used to determine frequency.

The bridge shown in Fig. 9 may be described as a resonance bridge, when X_u is inductive, since the arm $n\ q$ is made nonreactive at balance. A well-known and widely useful resonance bridge is shown in Fig. 10, which can be used to measure either inductive impedance $(R_u + j\ \omega\ L_u)$ or capacitive impedance

$$\left(R_u - j\,\frac{1}{\omega\, C_s}\right)$$

by using variable series capacitance C_s or inductance L_u to resonate the branch $n\ q$. It is also a convenient means of determining the frequency, using fixed condenser and variable self-inductor or vice versa. With a variable standard inductance this arrangment can be used like that of Fig. 9 for measuring inductive and capacitive impedances alternatively by simply placing the variable inductor in the $n\ q$ branch for measuring capacitive impedance, or in the $n\ p$ branch for inductive impedance, as was shown in Fig. 6. The methods described on page 6 for securing variation of effective reactance of fixed condensers or inductances can be applied to this bridge.

Next to be considered is the measurement of mutual inductance. A method which is also applicable to mutual capacitance and resistance, or stated generally, to mutual impedance determinations, makes use of bridges such as those already described. Consider two circuits, of impedances Z_2 and Z_2 respectively,

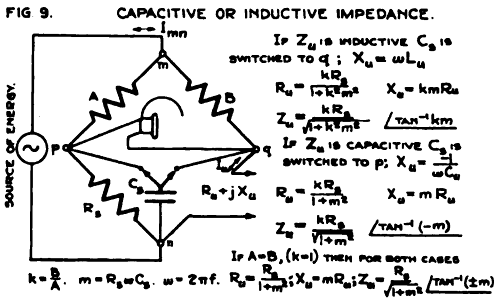

Fig. 9

and mutual impedance Z_m[1]. If connected in series the resultant impedance is $Z_a = Z_1 + Z_2 - 2\,Z_m$. By reversing the connections of one of the two, the sign of the Z_m term is reversed and the impedance is

$$Z_b = Z_1 + Z_2 + 2\,Z_m$$

Z_1 and Z_2 can be eliminated from these two equations leaving

$$Z_m = \frac{Z_b - Z_a}{4}$$

Where one terminal of Z_1 and Z_2 is common, for example the case of two earth-return wire circuits, the above

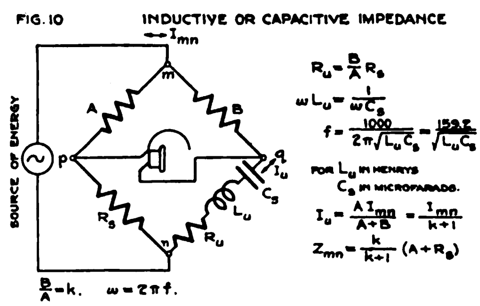

Fig. 10

procedure for obtaining Z_b is not possible. However by measuring Z_1, Z_2 and Z_a, Z_m can be evaluated, for

$$2\,Z_m = Z_1 + Z_2 - Z_a.$$

A check may be had by measuring the impedance Z_{12-0} from the two free terminals in parallel to the common terminal, but the formula for Z_m is complicated, being

$$Z_m = Z_{12-0} \pm \sqrt{Z_{12-0} + Z_1\,Z_2 - Z_{12-0}\,(Z_1 + Z_2)}$$

The use of this method and of the Fig. 10 bridge will

1. See Bibliography No. 5.

be illustrated by measurements on a retardation coil having two windings on an iron-wire core.

The frequency was first determined by balancing a 0.1004 microfarad condenser (C_s) with an inductance L_u = 0.379 henry, (using an inductometer), R_s being adjusted but its value not required. A and B were each 1000 ohms resistance. Their values likewise are not required for finding the frequency

$$f = \frac{159.2}{5.379 \times 0.1004} = 816 \text{ cycles per second.}$$

$$\omega = 5130. \quad \omega^2 = 26.3 \times 10^2$$

The resistance components, being small compared to the reactance components will for brevity be omitted from consideration, leaving only the reactances. The factor ω then cancels out, thus

$$Z_m = \frac{Z_b - Z_a}{4}$$

becomes $\omega M = \dfrac{\omega L_b - \omega L_a}{4}$

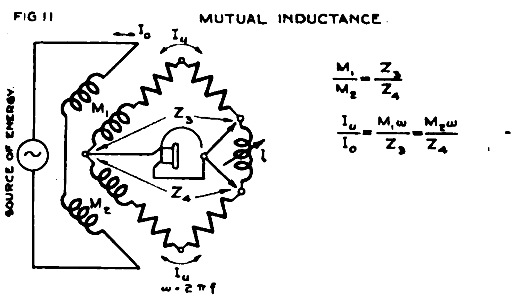

Fig. 11

or $M = \dfrac{L_b - L_a}{4}$

To find L_a, with the two windings in series aiding, C_s = 0.0141 microfarad whence

$$L_u\ (= L_a) = \frac{10^6}{\omega^2 \times 0.0141} = 2.70 \text{ henrys.}$$

Reversing connections, placing the two windings in series opposing; to find L_b, C_s = 0.0232 microfarad,

$$\text{whence } L_b\ (= L_u) = \frac{10^6}{\omega^2 \times 0.0232}$$

Thus L_u = 1.64 henrys.

M = 1/4 (2.70 − 1.64) = 0.265 henry.

The impedance of one winding, Z_1 the other being open-circuited, was as follows:

C_s = 0.0348 microfarad. R_s = 254 ohms = R_u

$$L_u = \frac{10^6}{\omega^2} C_s = 1.096 \text{ henrys } X_u = \omega L_u = 5610 \text{ ohms}$$

whence

Z_u ($= Z_1$) = 254 + j 5610 ohms.

The direct comparison of two mutual inductances is effected by the bridge of Fig. 11 (due to Maxwell). The impedances Z_3 and Z_4 include the inductive reactances and resistances of the secondaries of the mutual inductance coils M_1 and M_2, besides variable resistance. The small variable inductance 1 is made part of either Z_3 or Z_4 and is necessary to equate the phase angles of Z_3 and Z_4. With M_1 and M_2 known this bridge is available for ordinary impedance measurements, also.

The circuit of Fig. 12 is a very convenient method of determining frequency in terms of mutual inductance and capacitance, or for measuring either of the latter, if the other and the frequency are known. It depends

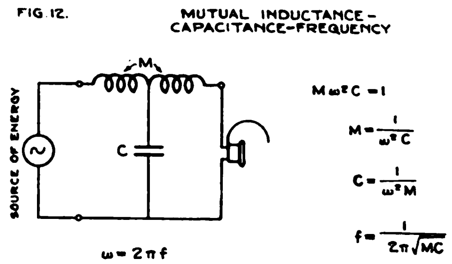

Fig. 12

for its effectiveness on the effective resistance components in the branch C and in the mutual impedance of the coil M being very small. If, due to eddy-current effects, the secondary induced e. m. f. of the coil M is not in quadrature with the primary current, or if there is energy loss in the condenser so that the potential drop across it is not in quadrature with the current, precise balance is not obtained. As an example, it was found impracticable to make a very close determination by this method of the mutual inductance of the iron-cored coil of which measurements were described above.

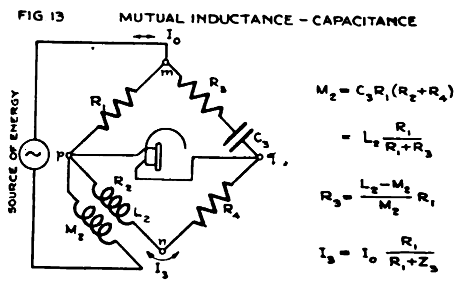

Fig. 13

Another bridge, (due to Carey Foster) for comparing mutual inductance with capacitance, is given in Fig. 13. The frequency is not involved in the equation. The method also permits the determination of the resistance of the arm containing the capacitance, so that the effective resistance of a condenser can be measured, and thus its power factor.

A bridge for comparing self and mutual inductances, (due to Heaviside) is shown in Fig. 14. A method of differences, (due to Campbell), which can also be applied in principle to other bridge networks, has been developed for the measurement of small self-inductances

using this arrangement. The bridge is first balanced, with $n - n'$ short-circuited. The inductance to be measured is then inserted between n and n' and the change in M_s to restore balance is observed. It is necessary that the self-inductance L_s of the secondary winding of the mutual inductance coil remain constant.

For the comparison of low impedances, for example in determining the conductivity of electrolytes, and cases where contact or leading in resistances are of importance, the Kelvin double bridge is used. The arrangement is shown in Fig. 15. Where, as in electrolytes, there is capacitive reactance effect, it may be necessary to shunt the standard resistance with a small variable condenser, to obtain exact balance.

An important use of bridge networks is the determination of unbalances, or the difference between two impedances or admittances; often of two sides of a circuit with regard to some common reference, usually "ground." The most obvious way is to measure each impedance separately. However, it is frequently the ratio of values that is desired and not the actual values. For this purpose, if the phase angles of the impedances

FIG. 14. INDUCTIVE IMPEDANCE-MUTUAL INDUCTANCE.

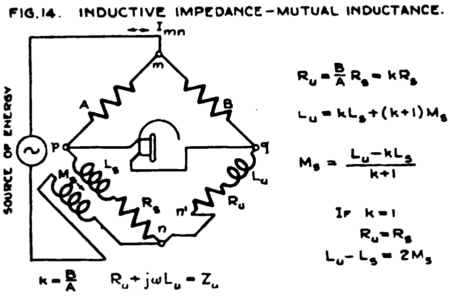

FIG. 14

being thus compared are nearly alike, the type of bridge shown in Fig. 2, 3, etc. having ratio arms A and B in adjacent branches, permits direct determination of the ratio of the impedances in the two other branches, by adjustment of the ratio $\dfrac{B}{A}$ to obtain balance. This method becomes unsatisfactory if the phase angles of the impedances being compared are unlike.

A bridge arranged to measure both conductance and capacitance components of the unbalance between two admittances Y_a and Y_b is shown in Fig. 16. As illustrated, a special condenser is so arranged that capacitance C is added to one side and subtracted from the other simultaneously as the condenser is shifted from its neutral position. The effect can also be secured by an ordinary condenser connected alternatively from p or q to n. A similar arrangement balances the conductances. At balance the readings of C and r show the difference between the two admittances Y_a and Y_b. To obtain the ratio or percentage of unbalance it is necessary to measure Y_a and Y_b.

The admittances of conductors sometimes depend on the condition of neighboring conductors. In the study of such cases the "direct admittances" are made use of.[2] The direct admittance between two conductors a and b is that admittance which obtains when all neighboring conductors are at the same potential as one of them. The dotted structure in Fig. 16 shows a method of adjusting the potential of conductors X to that of a and b, so that direct admittances or direct admittance unbalances can be measured.

In the above discussion of the various bridges where ratio arms have been shown they have been indicated

FIG. 15. LOW IMPEDANCE-KELVIN DOUBLE BRIDGE.

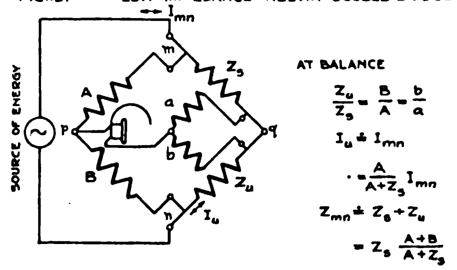

FIG. 15

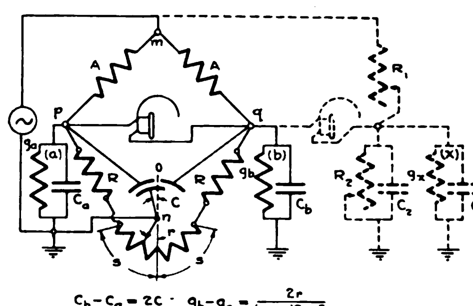
as resistances, according to the common practise of using nearly non-reactive resistance coils or slide wires. In cases where such ratio arms A, B are in adjacent branches, any two impedances having equal phase angles, such as for example, two condensers or two highly reactive coils can be substituted for such resistances, without altering the formulas.

While the use of unequal ratio arms provides a flexible bridge and greatly increases its range, simplicity in calculation and the minimizing of errors due to inexact realization of assumed conditions (for example,

FIG. 16 ADMITTANCE UNBALANCE



APPARATUS SHOWN DOTTED CAN BE ADJUSTED TO EQUATE POTENTIAL OF OTHER CONDUCTORS, X, TO THE POTENTIAL OF a AND b, BEING MEASURED.

FIG. 16

residual inductance or capacitance in assumed pure resistance coils) dictate the use of equal ratio arms wherever practicable.

Several different types of sources of energy at frequencies over the range from direct current up to radio frequencies, or over parts of this range, are available. It is not attempted here to discuss these. Among such are the various forms of alternator with rotating armature or field, or of the inductor type, the singing telephone or "howler," the microphone hummer,

2. *See Bibliography No. 5.

the Vreeland sine wave oscillator, and, most recently developed, the vacuum-tube oscillator. For a full discussion the reader is directed to references of the bibliography.

The most commonly used balance detector is the telephone which has the advantages of cheapness, simplicity, and ample sensitivity for all ordinary testing. It is most convenient at frequencies of from about 300 to a few thousand cycles per second, though measurements can be made at somewhat lower frequencies with it directly. However, small higher harmonics in the wave from the energy source have so much greater a factor of audibility that a pure wave shape is needed.

A method was developed many years ago to adapt the telephone to the direct-current Wheatstone bridge. This can be employed for measurements at very low frequencies. It consists of varying at an audible frequency the impedance of the balance detector circuit, so that whenever any current of low frequency exists in this circuit it will be broken up into audible impulses. The early device was a toothed wheel interrupter. A

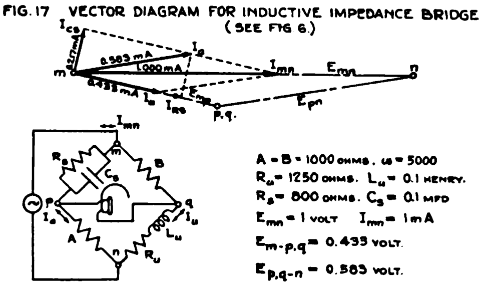


FIG. 17

modern method of achieving the same result is to connect a telephone transmitter in series with the balance detector telephone[3]. A telephone receiver, excited at an audible frequency, say 800 cycles is then used to operate the transmitter, thus varying the impedance of the detector branch.

For frequencies above a few thousand cycles, the heterodyne principle common in radio practise can be employed, the telephone receiver in the balance detector position being energized also by an auxiliary source of such frequency that the beats between the measuring frequency and this auxiliary frequency are audible.

Some forms of bridge, such as Figs. 2, 3, 7, etc. do not contain the frequency in the equation of balance. In practise this does not mean, however, that the bridge is simultaneously exactly balanced for all frequencies, because the resistances, inductances and capacitances usually change more or less with frequency. However, the tendency is toward balance, so that harmonics in the energy supply are not troublesome unless the wave shape is very poor. For other forms of bridge, such as Fig. 10, or any bridge that measures frequency, where balance is obtained by resonance, the bridge is definitely unbalanced at all frequencies other than the one for which the bridge is set. With such bridges purity of wave form of the energy source is important as observation of the silence point in a telephone receiver for one particular frequency becomes difficult or impossible as the noise from other harmonics is increased.

To purify the wave-form supplied to the bridge a filter or wave screen is often of advantage. The simplest form consists of an inductance coil and condenser in series with the energy source. It is also possible to resonate the detector circuit for the frequency under observation.

For precise work and especially at low frequencies the vibration galvanometer has been very successfully used. It is a much more complicated and delicate apparatus and is sensitively tuned to the frequency of the energy supply.[4]

As the frequency employed is increased the problem of guarding against current in the detector circuit, due

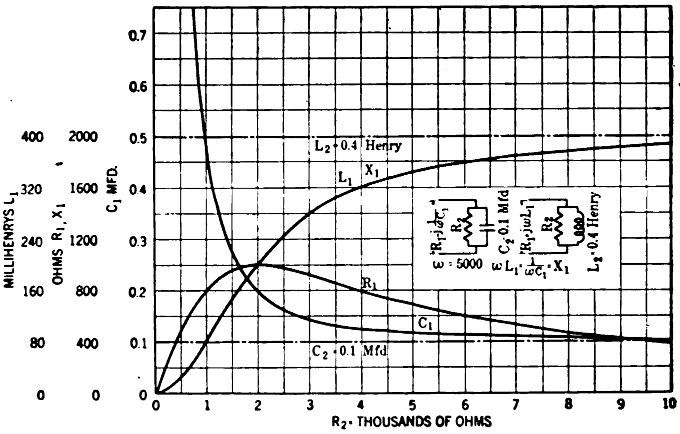

FIG. 18—EFFECTIVE RESISTANCE, REACTANCE, AND CAPACITANCE OR INDUCTANCE

Obtained by shunting condenser of 0.1 microfarad or inductance of 0.4 henry by a variable resistance, R_2.

to unbalances among the bridge arms and to ground, becomes more acute. To quote from Campbell:[5]

> The difficulty encountered lies mainly in the direct capacity between the different parts of the system. Since the ether permits the flow of alternating currents in all directions, the attempt to employ an ordinary balance for alternating measurements is much the same as the attempt to measure resistance with a Wheatstone bridge immersed in a conducting fluid, such as acidulated water.

For measurements at 1000 cycles and less this problem is only important in the more precise measurements. A simple device which is of aid in this connection is to connect the energy source to the bridge through a transformer having its neutral point grounded. Similarly, the balance detector may be connected to the bridge through a transformer. More elaborate arrangements are described in the literature.

CORRESPONDENCE

A-C. vs. D-C. Arc Welding

To the Editor:

Referring to Mr. Candy's comments on a-c. welding equipment in his article published in the Journal for June, 1920, it must be that he has drawn his conclusions from apparatus which he has constructed for his company. At least we know that no part of his comments refer to our a-c. welding machine although the article definitely classes all a-c. welding as poor. For instance, he makes the statement, "To make the equipment commercially successful in the hands of the average welder it is necessary to use an especially prepared electrode."

We have many installations in which bare wire electrodes are used, and some of them are not very careful as to what kind of wire they use. There is a firm using our apparatus which uses the core stiffening wire as it is removed from the castings, to weld up defects in the castings. Another firm regularly uses ½-in. diameter contractor's concrete-stiffening rods for welding up defects in castings. We have found firms using any kind of wire from hay wire to rusty nails, for electrodes, and while it is our claim that the best welding cannot be done except with good electrodes, we hereby make the statement that our machine will use any electrode that any other machine will use.

Mr. Candy also makes the statement that the a-c. arc is not so effective in fusing the metal as the d-c., assuming current only. In welding, the metal is evidently melted by energy, and current is only one factor, and while it is true that the power factor of the a-c. welding circuit lies between 0.88 and 0.92, yet due to the temperature of the arc being higher, and because the electrode is neither positive nor negative and the heat equally distributed at the same current the rate of electrode deposition has equally good results in welding and will be approximately 20 per cent faster with our type of welding transformer.

He next states, "the transformer is inherently a single-phase low power factor load (20 per cent to 30 per cent maximum)" With our machine 33 1/3 per cent is the minimum, and it ranges from this up to 63%. The reason we make single-phase machines is because they are much simpler and hence portable, and 4, 5, or 6 kw. is not worth while to distribute among the phases. If more than one machine is used they will be automatically distributed. Spot and butt welding run many times this demand, and it is not thought inadvisable even by Mr. Candy's company, to make these single-phase machines. The broad way of looking at it is, in the case of one machine, the unbalance is negligible, and in the case of many machines no unbalance exists, on any number of phases.

We have often been asked why it is that the power factor of our machine is higher than either of the largest electric concerns is willing to admit. It is well-known that besides the proper transformer characteristics there is a proper amount of resistance and reactance which cause the best combination for good arcs. By using the highest priced materials we have put this resistance in the machine, at the same time reducing its weight and making it portable and air-cooled.

In regard to the statement, "No thorough satisfactory means of limiting the open-circuit voltage to reasonably safe values (60 volts or less) has as yet been developed." We have had on the market for a long time, and equip practically all of our machines with an appliance so that the maximum voltage occurring at any time is 30 volts, and even the peak of the inductive a-c. kick is well below 60, *i. e.* around 45 or 50.

Mr. Candy also states that the operating cost of the a-c. machine is so much higher than the d-c., etc. We have made many tests against every type of d-c. machine and found that our figures of 1 to 2 kw-hr. per pound of metal deposited have never been equalled by any motor-generator type of welding apparatus. Furthermore, we guarantee the maintenance on our machine because we have never found it to exist to an extent that could be noted.

Power Factor Correction on Distribution Systems

BY D. M. JONES

Lighting Engineering Dept., General Electric Co., Schenectady, N. Y.

Power Factor Correction on Distribution Systems

POWER factor is a characteristic of electrical energy which is being transmitted by an impressed alternating voltage and resultant alternating current whereby it is possible for the current to rise and fall in magnitude before, with or after, the equivalent rise or fall in the alternating electromotive force. Tied up with this relative timing of voltage and current waves (which make up one pair of the cause and effect twins of the electrical family) is much of the hope and grief of the distribution game.

Development of Distribution

The development of the art of distribution of electrical energy has been practically dictated by the developments in electrical energy producing and consuming devices. The demand that distribution systems cover over larger areas has forced higher distribution voltages. The safety of the consumer and lower relative cost of manufacture in case of most small electrical power consuming devices has kept the mass of consumers' services at a relatively low voltage. This conflict of requirements could only be adjusted by a practical pressure charging apparatus.

The advent of the transformer as a device which very neatly did this work in a-c. circuits, easily gave this type of service a big lead in the distribution field. This lead was accentuated by the discovery of the principle underlying the induction motor and subsequent production of this motor for general a-c. commercial motor service.

The ruggedness and simplicity of the electrical and mechanical design of both the wound-rotor and squirrel-cage types of this motor early caused it to be considered by the consumer a most satisfactory appliance for converting electric energy to energy of rotating motion, and this attitude has resulted in practical limitation of d-c. motors in industrial service to either those conditions where a-c. service was not available or to special applications where large speed variation was desired with relatively high torque at low speeds. In this latter field the d-c. motor is still pretty well entrenched on account of its inherent ability, not only to meet the above conditions, but even to do so with relatively high efficiencies.

Two notable exceptions to the above general tendency towards the use of alternating current, however, exist: The d-c. distribution networks covering the dense business sections of some of our largest cities; and the use of direct current in electrical traction activities.

The d-c. network generally has a basic historical reason for existence. The natural place for first electrical lighting plants to appear was in the heart of the largest cities and as these first plants were all d-c., the distribution systems in these spots started as d-c. systems. When the a-c. generating station arrived there was so much d-c. equipment in operation in the section, that it was less of a convulsion to substitute converting devices for changing the a-c. power received from new central stations to d-c. power to fit the old equipment, than to change our whole system to a-c., that this solution was generally adopted. Another potent argument for the d-c. service in these congested sections was the fact that it could be backed up with a storage battery; (generally of capacity to carry full load for 15 minutes) which did away with the possibility of short failures of power with attendant danger to life and property in these dense sections. Now, however, (a) the improvement in reliability of a-c. distribution due to the improvement of general equipment and construction practises, and also to the development of automatic control features; (b) the relatively lower cost of a-c. distribution due to absence of synchronous converters and storage batteries and reduction in quantity of copper required due to the fact that with a-c. distribution the power is generally brought much nearer to consumer at the higher voltage; (c) the reduced upkeep and attention; due to absence of converters and batteries above mentioned; (d) and finally the habit a d-c. network has, when it once does go dead beyond the ministering aid of the storage battery, of going dead all over; have not left it in undisputed sway even here, but rather in the position where it must fight harder for its grasp on the situation with passing years; particularly, when it is a matter of determining the type of new installations.

In the traction field the incomparable excellence of the d-c. motor, as compared with the a-c. type, has always kept most of the trolley wires of the world carrying d-c. power. This has not been without aggresive competition, especially in the realm of heavy haulage where the a-c. motor bids fair to divide the honors for a time. At present, however, the ultimate distribution of the electrical energy for traction purposes is increasingly done in d-c. form.

Bad Power Factor a Dangerous Condition

It is thus evident from the foregoing that power factor, being a characteristic of a-c. distribution, is a phenomenon, whose field of influence already is widespread; and it is broadening at almost a cumulative rate. The fact that the electrical energy delivery team (current and voltage) in an a-c. system have the capacity of doing more or less work for their size, as

To be presented at the Pacific Coast Convention, A. I. E. E., Portland, Ore., July 21–23, 1920.

one might say, according to whether they pull together or not; suggests at once the advisability of seeing what can be done to get the most out of them. This advisability is accentuated by an appreciation of the fact that the capacity of the electrical end of generating equipments and distribution systems is based upon the size of "current" the "off-horse" of this team, and not upon the work the team accomplishes. And again, since the electrical losses throughout are dependent, not only upon the magnitude of the current value alone, but even increase with the square of the current value, it is evident that in a large measure this animal also eats according to the size of his frame and not according to his productive activities.

Its Relation to Capital Invested

The fact that the load of power systems varies cyclically with the hours of the day and that the maximum current demand for the day, in the past, has generally come with the evening lighting peak, which is an inherently good power factor load, has made many careless as to what the power factor of the lesser loads through out the day was, as the lighting peak had dictated the current-carrying capacity of the distribution system.

When this low power factor industrial load, which had generally been welcomed at a reduced rate as a filler of load curve valleys, began to demand the expenditure of money for distribution capacity due to its presence, beyond that which was demanded by the evening peak, it challenged attention to the seriousness of the evils of bad power factor from the economic standpoint. For example; the capital cost of central station system beyond the generating station bus per kilowatt-hour delivered per year will vary over range of approximately 2 cents for large dense installations to 12 cents for small extended distribution systems. Assuming 4 cents capital investment per kilowatt-hour delivered per year and 15 per cent interest and depreciation charge on basis of 90 per cent power factor at maximum current demand as a concrete case, the interest and depreciation on transmission and distribution systems per kilowatt-hour delivered will be 6/10 of a cent.

If the power factor of maximum current peak were now arbitrarily lowered to 60 per cent and load remained the same, and assuming general transmission and distribution investment were increased proportionally with current increase, the interest and depreciation per kilowatt-hour delivered for the year would be increased 50 per cent. The capital charge would now be 9/10 cent instead of 6/10 cent for each kilowatt-hour delivered; or an increase of 3/10 of a cent in delivered cost of every kilowatt-hour, due to increased capital charge occasioned by the drop in power factor from 90 per cent to 60 per cent lagging. Such a saving would buy the coal under average conditions for some plants.

Effect on Losses

The increased I^2R losses with the change for the worse of power factor are often considered negligible and are admittedly difficult to reduce to the concrete.

Let us consider however the copper losses in a three-conductor 250,000 cir. mil. distribution cable carrying 60-cycle 15,000-volt three-phase power, which is a fairly representative condition. Assuming an average daily load curve on the cable with load factor of 53½ per cent and current of 200 amperes at evening peak, as shown on Fig. 1 with power factor varying from 90 per cent at peak to 60 per cent throughout day as shown by power factor curve on above mentioned figure we have the following results:

Total kw-hr. per year delivered over cable 21,900,000.

Total I^2R losses for year per mile 144,000 kw-hr. Or about 66/100 of one per cent of power delivered disappear in I^2R losses per mile of cable. If now the power factor of above assumed load were brought up to a constant value of 90 per cent throughout 24 hr. the above results are changed as follows:

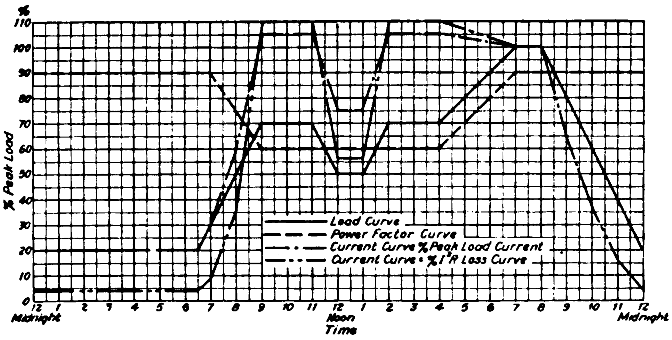

Fig. 1

The I^2R losses per mile per year are reduced, to 88,500 kw-hr. or about 4/10 of one per cent with a saving in losses of about ¼ of one per cent of power delivered per mile of cable carrying load under conditions as assumed.

In these days when demand for electric energy is in excess of the available supply, the elimination of losses means additional power sold. On this basis the raising of the power factor of the load up to a constant value of 90 per cent and resultant reduction in losses of ¼ of one per cent per mile of cable would make available for consumers 55,500 kw-hr. per year for every mile of distribution cable in service under equivalent conditions.

If this power were sold at 3 cents per kw-hr. a revenue of $1665.00 per year would be received per mile of cable for what under first condition went into heating the cable. Furthermore, the power would have become available during the day load period when wanted as shown by shaded area on Fig. 2.

Power Factor and Regulation

Besides these primary evils of excessive capitalization costs and unwarranted losses, the secondary effect

of bad regulation chargeable to bad power factor is in practical experience as serious as the primary evils.

The demand for excessive generator excitation under lagging power factor conditions so thoroughly appreciated by operators, though strictly beyond the scope of this discussion, cannot be passed unmentioned.

The excessive voltage variation produced in distribution wires and cables and especially on transformers by conditions of bad power factor are facts both within our field and worthy of consideration. This voltage variation is aggravated by conditions of power factor not only by the fact of the unnecessary magnitude of current for given power transmitted but in the case of the average condition, where the power factor is lagging, the delay of the current wave behind the voltage wave tends to make the voltage induced in the reactance of the lines and transformers directly subtractable from the generated voltage, while in case of unity power factor condition, this voltage is in quadrature and has small effect on magnitude of line voltage.

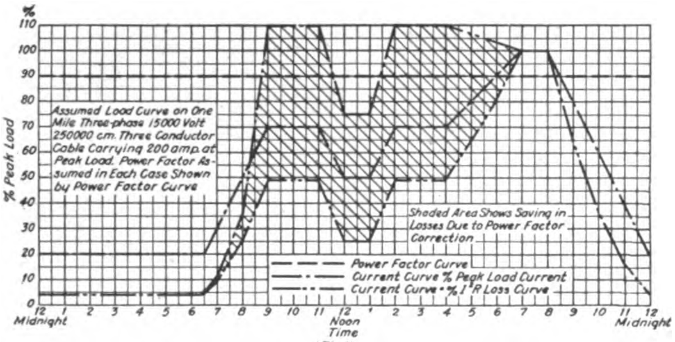

FIG. 2

As an instance of this consider the average 60-cycle 2300 to 220/110-volt type of distribution transformer. Such transformers are commonly produced with resistance of from 1 to 1¼ per cent and with reactance of 2¾ to 4½ per cent over range of capacity from 1 to 250 kv-a. or more. Full load on transformer of this type with say 1¾ per cent resistance and 3½ reactance means a drop in voltage at unity power factor of about 1.8 per cent of line voltage which at 0.7 power factor lagging becomes 3.7 per cent drop or a little over double what it was with the same current flowing in transformer as at unity power factor or nearly 3 times the drop that would have occurred in delivering same power at unity power factor.

In the case of the substation transformer working between voltages from 6600 to 15,000 volts or more down to voltages of 4600 volts or less, a representative example may be considered to have 1.3 per cent resistance and 6 per cent reactance. Here the full-load voltage drop with unity power factor would be about 1⅓ per cent of normal voltage, while with the same kv-a. load on transformer and power factor of 70 per cent lagging the drop would become about 5.2 per cent or nearly 4 times its previous value, and about 5½ times more than would have occurred on basis of equal power transferred. It is fairly evident therefore, that transformers become vicious voltage "ir-regulators" with power factor variation even at constant load.

Sources of Bad Power Factor

The review of these evils of bad power factor bring at once to mind the question of probable causes and available remedies for this condition.

The Induction Motor and Power Factor

Probably the most prevalent source of the trouble is found associated with the use of the induction motor.

The use of too large a motor, resulting, it is regrettable to say, from a misapplication of good intentions, is a practise which has been one of the chief offenders. Past experience in installing motive power of other than the electrical variety has taught the lesson of liberality in selection of capacity and this has naturally resulted in the same tendency in many cases in the selection of motor sizes.

The seriousness of the result will be appreciated when it is remembered that the lagging magnetizing kv-a. on general line of 60-cycle induction motors, runs from 30 to 60 per cent of the full load kv-a. and holds practically constant in a given motor over whole load range.

For example, consider an induction motor which at full load has a power factor of 85 per cent, at ¾ load it will drop to 77 per cent power factor, at ½ load it will drop to 62 per cent power factor, at ¼ load it will drop to 38 per cent power factor. Inasmuch, as the per cent magnetizing current generally increases with decrease of rated speed and with decrease of h. p. rating, it is at once evident that the small induction motor which forms such a large proportion of total connected motor load, is probably one of the most vicious of the species. This is due not only to the fact of the inherent low power factor at full load; but more particularly to the fact that due to its small size; its installation is given very little engineering consideration and capacities are frequently poorly selected.

This general condition has proved of sufficient practical importance to power companies to have resulted in certain of them in the cotton and woolen mill districts of New England accepting the responsibility of checking the customer's motor installations in this respect. The result of these investigations has generally been a more or less extensive overhauling by the customer of his motor installation for the purpose of operating all motors at better load factors, with resultant improvement in power factor highly satisfactory to both parties.

The power company is able, by the change, to furnish better voltage regulation at the same load, and with diminished losses, or handle an increased power load over the transforme and distribution lines at no increased cost for gen..ating equipment,

transformers or distribution copper; while the customer finds himself with an improved drive and generally a few idle motors on hand, for emergency service or extension purposes, which were previously tied up on his lines.

Activities in the industrial field which result as plainly in mutual good are highly inviting in these days of intensified group strife.

The Transformer and Power Factor

The same bill of complaint can be brought against the transformer though in a lesser degree, for this appliance also takes a constant lagging magnetizing kv-a. at a given voltage; but its magnitude is smaller than with the induction motor, varying from 1 to 15 per cent of full load kv-a. as the higher percentage values of magnetizing current in general appear in power transformers, this larger lagging kv-a. in general is added to the over-abundance already being taken by the induction motors comprising the power load.

That this magnetizing kv-a. of transformers is not entirely negligible in extreme cases may be seen from the following:

A transformer with 15 per cent magnetizing current, carrying normal secondary load at unity power factor would take primary power at approximately 95 per cent power factor which would drop to 90 per cent power factor if its secondary load were reduced to one-half normal and to 84 per cent power factor if it were again reduced to one quarter normal.

Effect of Over-Voltage on Power Factor of Induction Motor

Even the values of magnetizing current just given for induction motors and transformers may be materially increased with the raising of the applied voltage above that for which the appliance is rated.

Since induction motors when run at 10 per cent over-voltage may easily take a magnetizing current 20 to 25 per cent in excess of that required, at normal voltage, it is evident that it is possible to find conditions where the disturbing effect of induction motors on power factor may even be much in excess of that previously delineated.

Over-Voltage on Transformer in Relation to Power Factor

With the transformer, the application of over-voltage is even more serious than with the induction motor, in this respect, due to the lack of any air gap in its magnetic circuit.

The pole type variety of this appliance, which is generally forgotten after once installed, and considered to be operating satisfactorily unless emitting smoke, though designed for low iron losses, will often sustain a 50 per cent increase of magnetizing current at 10 per cent over-voltage which amounts to 55 per cent increase in lagging kv-a. taken by the appliance.

The power transformer of larger size such as typically used for handling industrial customers who are supplied on separate feeders, or such as are installed in the power company's substation for reducing the higher distribution voltage to that of the substations feeder bus, is a much more serious offender than the pole type in matters of the above nature. Not only do they take a larger percentage exciting current at normal voltage due to the fact that they are expected to operate at better load factor than transformers of the pole type, and, therefore, iron and copper losses are more nearly equalized; but also sustain a greater increase in this current with increase of voltage. In fact the magnetizing current may frequently double with 10 per cent increase in voltage above normal, making the statements previously given on basis of normal voltage conditions much too conservative. It becomes apparent, therefore, that in some cases, transformers also can make themselves distinctly felt as destroyers of good power factor conditions.

Miscellaneous Sources of Bad Power Factor

Besides of these causes of trouble, there must also be mentioned certain more specialized types of electrical appliances which inherently produce a low power factor load of which the bad power factor can only be corrected for, not provided against. Common examples of these types are electric welding machines, arc furnaces and some types of heating appliances.

The problem here, however, is a localized one of special nature, rather than a general condition and should be handled on that basis.

A more unusual and unique condition is that occasionally found in systems where the transmission network is very highly extended in proportion to load carried by it, with the result that the capacity current taken by the lines is so large in proportion to the load current that bad power factor means a leading power factor and an induction motor becomes a corrective device. Such cases are not hypothetical, for there comes to mind such a system in the Middle West adjacent to one of the standard lagging power factor characteristics where considerable consideration has been given to interconnection whereby each would act as a power factor corrective device for the other.

Synchronous Motor in General As A Remedy for Bad Power Factor

In eliminating bad power factor at its source, a most valuable ally is the synchronous motor. This device has been on the market for twenty years or more; but until recently was considered so limited in its application, both on account of its torque characteristics and greater trouble in starting, due to the necessity of switching on field and synchronizing, which were wont to be considered as delicate operations; that it is probable that less than 5 per cent of the motor horse power in this country today is of synchronous variety.

Recently this motor has begun to come into its own

due to steady improvement in its design characteristics and simplification of starting equipment, and also to increasing familiarity of operating public with this type of device. Slowly this motor has enlarged its usefulness until it now may properly be given consideration on any constant speed application which can be handled by an induction motor.

The fact that the synchronous motor has actually been applied with good results to the drive of compressors, grinders, stone crushers, pumps, both centrifugal and plunger blowers, steel and copper rolls, cement and rubber mills, flour mill rolls and line shafting in general, is concrete evidence of the fact that this motor has already covered a wide field in its application.

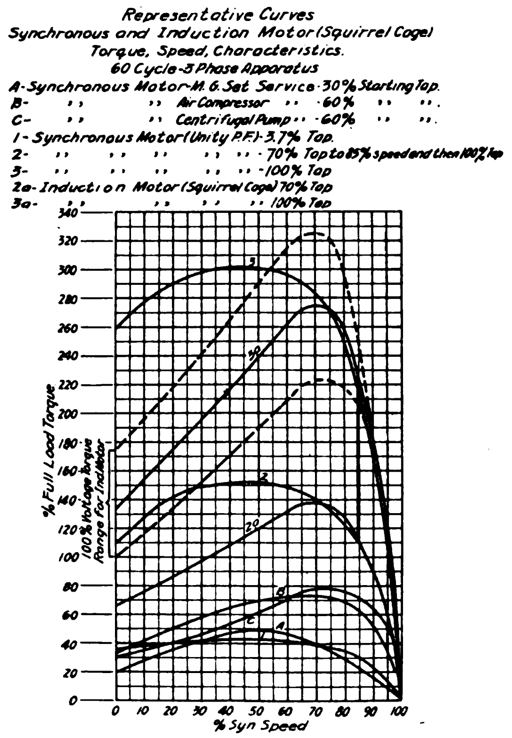

FIG. 3

UNITY POWER FACTOR SYNCHRONOUS MOTOR

When operated without capacity for over-excitation of its field, this device takes energy at unity power factor and even then, in a real sense, is a power factor corrective device, for it relieves the system of the lagging kv-a. that would have been added by the induction motor and thus by the substitution, really furnishes corrective kv-a. to the system of probably 30 per cent of its normal rating.

Synchronous motors of this particular type have recently become available in a consecutive line over approximate range from 50 h.p. at 1200 rev. per min. to 450 h.p. at 600 rev. per min. specifically designed to invade as far as possible, the field of motor application now held by the induction motor, with representative results for particular ratings which are very encouraging, as to the future of the device.

Referring to Fig. 3 and 4 giving comparative representative torque-speed and kv-a. input-speed curves respectively for standard synchronous motors, induction motors and unity power factor synchronous motors above mentioned, it may be interesting to note that with about 60 per cent as much kv-a. the unity power factor synchronous motor will easily duplicate the starting torque characteristics of the standard synchronous machine for motor generator set service. Comparative inspection of curves 2 and 2A giving relative torque characteristics of unity power factor synchronous and squirrel-cage induction motors when operated from 70 per cent voltage tap reveals the fact that the synchronous motor up to about 85 per cent speed delivers well above full load torque and from kv-a. input curve 2 it is evident that maximum input is approximately only 3½ times normal kv-a. At

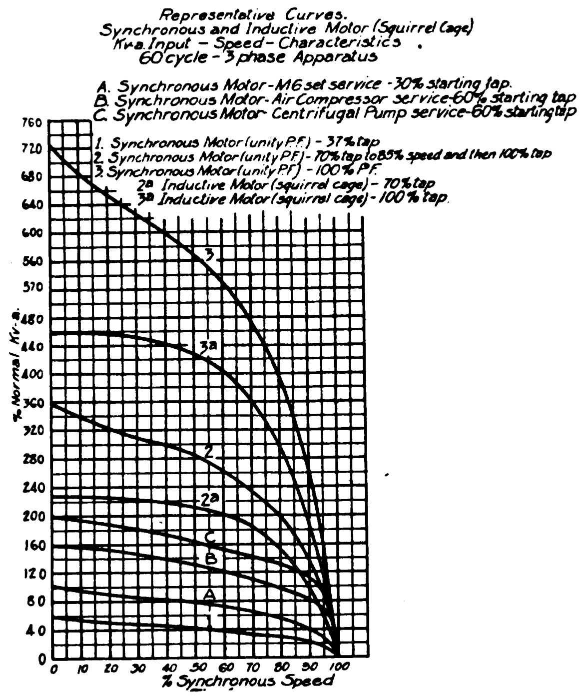

FIG. 4

speeds above 85 per cent the torque characteristics of these two types are very similar. It is also entirely feasible at the 100 per cent torque, 85 per cent speed condition to throw full voltage on the synchronous motor when it would pass over to full voltage characteristic and again take a maximum of about 3½ times normal kv-a. and develop a torque which would not drop to the normal full load value until 95 per cent speed were reached. From 95 per cent speed and full torque condition it would then pull into step, by application of the field. In other words, this last fact means that with motor at full torque load and synchronous speed the field could be removed and motor would drop to 95 per cent speed only and again pull into step with reapplication of the field. It is clear also from full voltage curves, that the maximum torque of this type of synchronous motor is entirely comparable with that of squirrel cage induction types.

Nevertheless it must not be considered that such a motor will handle any application on which the induction motor, even of squirrel-cage design, can; for as a general thing the squirrel-cage induction motor will develop the comparative starting torque for a much longer time with the same temperature rise in the squirrel cage winding, than will the synchronous competitor. Therefore, when the total amount of momentum to be stored up in rotating mass of the driven appliance, during starting cycle, is very large, it is possible to exceed the safe temperature limits of the starting winding in the synchronous machine.

This class of load is apt to trouble even the squirrel-cage motor and, by the conservative, would be assigned to the field of the wound-rotor induction motor, which by proper selection of external resistance can be arranged to give maximum torque at any speed up to full torque speed and, due to considerable heating being in grids, external to machine, has capacity for maintaining large torque for comparatively long periods of time.

Since the wound-rotor induction motor, due to higher cost, is generally reserved for installations with exceptional starting duty requirements, or speed variation capacity, it is not so general in its use and comparative in its duty, as is the squirrel cage type. Due to this, in conjunction with the fact that the torque-speed-input-speed characteristics are functions of the starting resistance and result in an infinite series of curves to cover all possibilities, no attempt has been made to include the wound-rotor induction motor in the detailed comparison, though in some applications, even this device can be supplanted by the synchronous machine.

It is evident, therefore, that considerable relief from the extension of the bad power factor in the future, should be obtained by the increased use of the unity power factor synchronous at the expense of the induction motor. This method of treatment is especially advantageous as it eliminates the lagging kv-a. of the induction motor that would have existed instead of correcting it after it has been added.

Phase Modifier as a Power Factor Corrective Device

Another method of bad power factor elimination which is better known in European practises than with us, is the use of the phase modifier. This scheme is practically that of furnishing an exciting voltage of proper magnitude, frequency and phase relation to the rings of the wound rotor induction motor, the power factor of which it is purposed to raise. The limitations of this device from an engineering standpoint are due to the facts:

(1) That it is impractical to use with a motor which is frequently started.

(2) That the amount of correction is dependent upon the design and also load on the induction motor, is unsusceptible of variation at will, is practically limited by relative cost of modifier to corrective necessary to bring the induction motor load to unity or less.

(3) That it is not operative without the induction motor.

(4) That it is applicable only to constant speed, non-reversable, wound-rotor induction motor.

(5) and finally that the scheme necessitates an additional machine either driven separately or by the induction motor.

The commercial possibilities of the device lie in offsetting the cost of the additional machine, by the saving in cost of the induction motor designed for high iron densities and resultant high magnetizing current, and by the capitalization of the increase in power factor obtained by modifier over what would have been obtained from standard designed induction motor. The fact that the standardized factory production methods of the country make it very difficult to lower induction motor costs by deviation from standard design, may possibly account for the limited exploitation of this method of power factor correction within our own field.

Over-Excited Synchronous Motor as Corrective Agency

With the application of the synchronous motor, with ability for over-excitation to a system, corrective capacity can be obtained for bad power factor conditions already existing in amounts variable at will up to the limits of the machine and in a very economical way. This fact is evident when it is remembered that the additional corrective kv-a. of the motor does not add directly to the load kv-a. with the result for example, that a motor having a rating of 80 kv-a. at unity power factor would have a rating of only 100 kv-a. at 80 per cent leading and yet would add to itself a power factor corrective capacity of 60 kv-a. That is to say, by increasing the machine rating 25 per cent above unity power factor rating, a corrective capacity is obtained equal to 75 per cent of the original rating of the machine.

Wherever, therefore, it can be arranged to use a synchronous motor for power purposes, it can be selected to furnish a considerable amount of corrective kv-a. at a very low first cost and operating expense, as the major portion of both is chargeable to the power load.

A notable example of the application of this principle is found in the use of the synchronous motor-generator set in the substation. Where there is a combined demand for direct current, generally for traction purposes, and for a-c. energy localized around one substation, it is very convenient to obtain the direct current from the generator of a motor-generator set and power factor correction for a-c. load from synchronous motor of the same set.

Although the 60-cycle railway converter both as a

normally and automatically operated device is on firm ground as a satisfactory piece of electrical equipment, the motor-generator set on account of relatively large capacity for power factor correction is a very active competitor of the synchronous converter in many cases and lends itself admirably to any demand for automatic control.

Synchronous Condenser as a Power Factor Corrective Appliance

When the demand for over-excitation on a synchronous motor is pushed to the limit and becomes entirely dominant in the design, we have the synchronous condenser, which is a motor to the extent only of revolving itself and a provider of leading corrective kv-a. to practically its total rating.

The adaptability of this machine is very high as can be illustrated by the fact that it is made in voltages from 220 or below to 13,000 volts or better in sizes from approximately 100 to above 30,000 kv-a.

The secondary effect of the variation of voltage drop, due to changes in power factor, has so often been made use of in connection with the synchronous condenser, that it is often used primarily as a voltage regulator. It lends itself admirably to this purpose as the excitation of the condenser can be automatically controlled so that by thus varying the power factor of the line, constant voltage can be held within the limits of the capacity of the machine. The condenser may even be arranged to place itself on the line and take itself off again as need for it is evidenced by the value of the line voltage; or even as determined by the dictates of a time clock.

The disadvantage of synchronous condensers lie in the fact that there is no power output which can be called upon to share the cost and operating expense with the power factor corrective capacity and these factors therefore, mount rapidly as compared with the synchronous motor situation. As a power factor corrective device only, it is, however, easily the leader in general usefulness and without it large problems of a-c. distribution and transmission would be difficult of solution.

Static Condenser

One of the newer agencies for power factor correction which overlaps in its field of application, the low capacity end of synchronous condenser territory, is the static condenser which is nothing more than the commercial application of the "Leyden Jar" to the problem of power factor correction.

As compared with the synchronous condenser, it has the following disadvantages:

(1) Is practically of fixed capacity as operated.

(2) Corrective capacity is leading only, not leading or lagging as desired, as with synchronous condenser.

(3) Takes more floor space per kv-a.

(4) In large sizes costs more per kv-a.

These shortcomings far from remove its usefulness, as it has the following outstanding qualities of merit.

(1) Very low losses (1 to 2½ per cent, while synchronous condenser losses vary from approximately 10 per cent to 3 per cent with increase of size).

(2) No rotating parts, therefore, no lubrication costs. no bearing wear and no noise.

(3) Less attendance.

(4) Easier to put on or take off line—accomplished simply by closing or opening an oil circuit breaker.

(5) Operates at low temperature rise and, therefore, does not heat up operating room as much as a synchronous condenser.

The limits of the field of application of this type of apparatus in competing with the synchronous condenser, are for practical purpose those of economic balance and not those of design, for the static condenser can be furnished in any capacity by continued multiplying of condenser sections. The practical usefulness of the static condenser can be best exemplified by the fact that there is today in process of manufacture a total kv-a. capacity, equal to the total capacity produced over the whole eight or nine-year period of its manufacture.

Power Factor Corrective Engineering

Having arrived at the conviction that power factor correction is generally a thing to be attempted it might be worth while to point out that the sane way to go about it is:

First—To locate its causes.

Second—Remove the causes insofar as practical.

Third—If correction is still needed, install corrective devices as near the source of bad power factor as possible, limited by the economic fact that power factor corrective devices cost more per kv-a. in small units.

The limit to which correction should be carried may be arbitrarily set:

(1) By voltage regulation requirements.

(2) By balance of yearly value of savings against yearly cost of correction.

(3) By economic balance as described under (2) supplemented by power factor penalties and bonuses (one or both) in power rate.

(4) By necessity of carrying more power over available distribution lines irrespective of economic balance.

(5) Or even, by condition that has recently risen in the East, when for lack of available power, customers were limited by power companies to a certain kv-a. demand. In such a case, it was found advisable for certain customers to correct the power factor absolutely up to unity, so critical was the need for the additional power. The urgency of the case can be better appreciated when it is remembered that for addition of say 10 per cent of load kv-a. in power factor corrective kv-a. to load, with an initial power factor of 70 per cent

the reduction in load kv-a. would be about 7½ per cent of original kv-a. load. By addition of successive amounts of corrective kv-a., 10 per cent addition at 80 per cent power factor condition would reduce kv-a. by about 5½ per cent of original kv-a., and last 10 per cent necessary to bring load up to unity power factor would effect a reduction in load kv-a. of only 8/10 of one per cent of original kv-a.

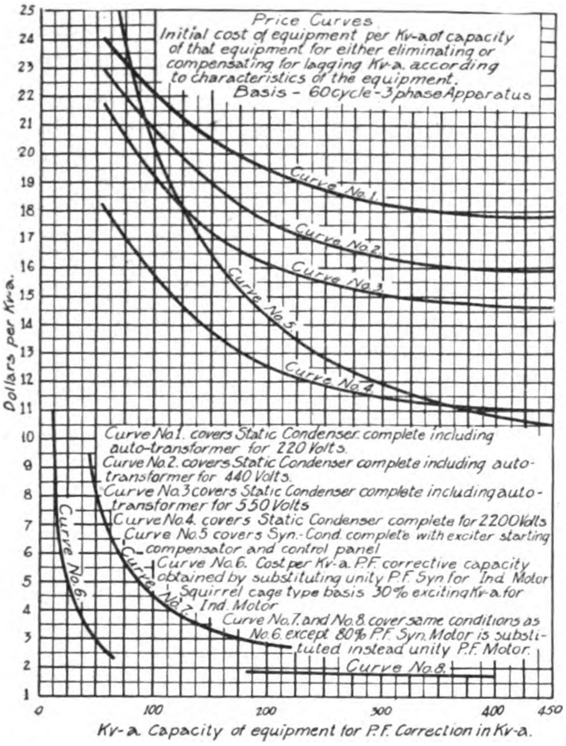

Fig. 5

Analysis of the Cost of Different Power Factor Corrective Devices

The final question in this situation is sure to be, "what will it cost?" and some general facts on this may be fittingly considered.

Referring to Fig. 5 for approximate information on 60-cycle motor prices—curve No. 1 gives price per horse power of 80 per cent power factor synchronous motor complete with exciter and starting equipment in capacities ranging from 50 h.p., 1200 rev. per min. to 450 h.p., 300 rev. per min.

Curve No. 2 furnishes equivalent information on wound-rotor type of induction motor complete with starting equipment in sizes 50 h.p., 1200 rev. per min. to 250 h.p., 600 rev. per min. and continues in curve No. 5 over a range from 250 h.p., 450 rev. per min. to 450 h.p., 300 rev. per min.

Curve No. 3 covers the unity power factor synchronous motor complete with exciter and starting equipment, over range from 50 h.p. and 1200 rev. per min. to 450 h.p. and 300 rev. per min.

Curve No. 4 represents prices of induction motor, of squirrel cage variety complete with starting equipment, in ratings from 50 h.p., 1200 rev. per min. to 250 h.p., 600 rev. per min. which continues in curve No. 6 over range from 200 h.p., 450 rev. per min to 450 h.p., 300 rev. per min.

Using the above price curves as a basis supplemented by assumption of 30 per cent exciting kv-a. for induction motors throughout, we have Fig. 6 on which curve No. 1 represents the power factor corrective kv-a. that would be added to systems by substitution of a unity power factor synchronous motor for induction motor of same rating, plotted against the motor rating.

Curve No. 3 represents the power factor corrective kv-a. obtained by similar substitution of 80 per cent leading power factor synchronous motor.

Curve No. 2 shows price per kv-a. of power factor corrective capacity obtained against the size of each of the two motors wherein substitution was made in case where unity power factor synchronous motor was used as a substitute for squirrel cage induction motor, while curve No. 4 gives equivalent information in case 80 per cent power factor leading synchronous motor were substituted.

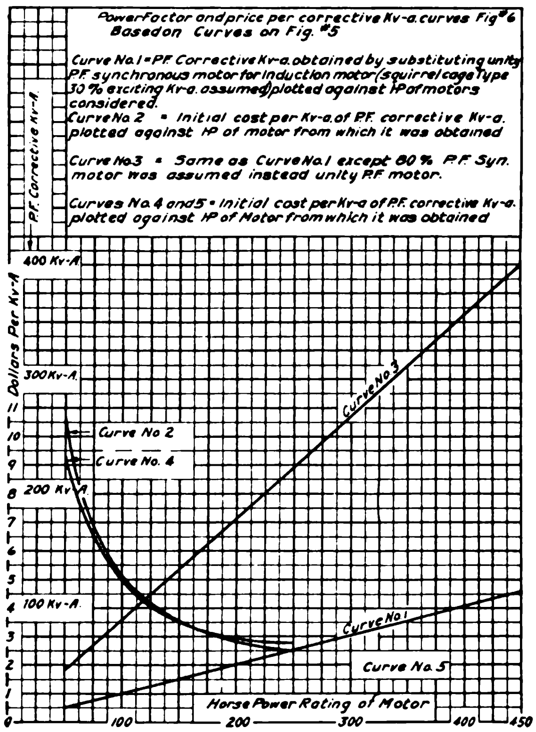

Fig. 6

Curve No. 5 continues the comparison over a range from 250 h.p. at 450 rev. per min. to 450 h.p. at 300 rev. per min.

The comparison fails in this range for unity power factor size motor, as it probably will not cost more than the induction motor of squirrel cage type.

The interesting fact becomes evident that in case either substitution is practised the price per power factor corrective kv-a. obtained is about the same for a given motor size although of course the total amount

obtained is approximately three times as much with 80 per cent power factor motor as with unity power factor variety. The choice of type of synchronous motor will therefore be made on the basis of relative characteristics and amount of corrective kv-a. desired.

In Fig. 7, we have a comparison of price per kv-a. of obtaining power factor corrective kv-a. by the several methods.

Curves 1, 2, 3 and 4 give price per kv-a. of static condensers complete for voltages of 220, 440, 550 and 2200 respectively; the variation in price being accounted for by the fact that the condenser voltage in 200, 440 and 550-volt instances is reduced by an auto-transformer to meet rated voltage, and the greater the reduction, the greater the auto-transformer price per kv-a. of static condenser.

Curve No. 5 represents the price per kv-a. for 60-cycle, three-phase size condenser complete with exciter

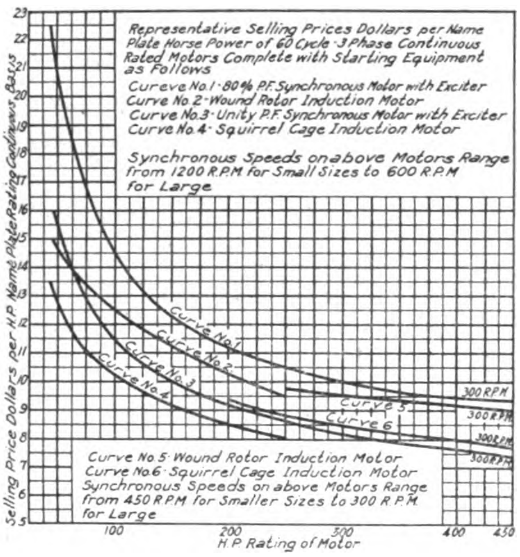

Fig. 7

and starting equipment and it should be noted that for small sizes even the initial investment is less for the static condenser.

Curve No. 6 shows price per power factor corrective kv-a. obtained by substituting unity power factor synchronous for squirrel cage induction motor, plotted against the amount obtained over the range of motors 50 h.p. to 250 h. p. giving a maximum of approximately 65 kv-a.

Curve No. 7 brings out the cost per power factor corrective kv-a. obtained by substitution of 80 per cent power factor synchronous motor for squirrel cage induction motor over range 50 h.p., 1200 rev. per min. to 250 h. p., 600 rev. per min. giving a maximum of about 223 kv-a., and curve No. 8 continues this information over motor range from 200 h.p., 450 rev. per min. to 450 h. p., 300 rev. per min. reaching a maximum available power factor corrective kv-a. of approximately 400.

A casual observation of these curves should convince one of the advisability of using the substitution method of obtaining power factor corrective kv-a. to the extent that it is possible of application.

The limitations of the substitution method are obviously due to necessity of disposing of replaced induction motor at no loss to comply with the assumptions. In case of new installations, this is entirely applicable; in other cases, the prices given must be increased to cover loss, if any, on replaced motor.

The difference between curves No. 6 and No. 7 should not be misconstrued. From curves it would seem that a cheaper way to obtain given corrective kv-a. can be found with the use of unity power factor motor in substitution game, than by the use of 80 per cent power factor type. It should be remembered that to get the same amount of correction as can be obtained by substituting a 100-h.p. 80 per cent power factor synchronous motor for a squirrel cage induction motor, it would be necessary to substitute a unity power factor synchronous motor for an induction motor of about 350-h.p. rating. As the cost per

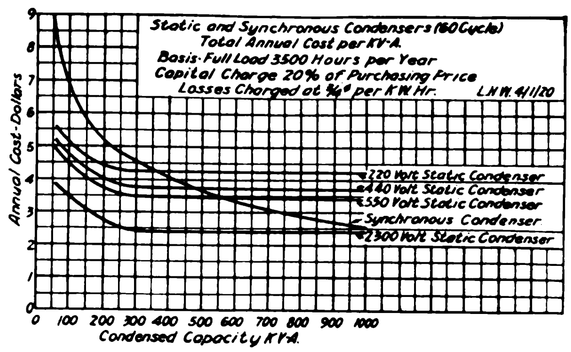

Fig. 8

corrective kv-a. goes down with increase in size of motors considered, it is seen that the conditions above stated are not justly comparable. It is much better to remember that for a certain motor in question to be substituted the price per corrective kv-a. obtained with either type of synchronous motor is about the same but the amount is greater with the 80 per cent power factor type.

There has been no attempt to include the capitalization of the difference in efficiencies of the two general types, *viz.* synchronous and induction motors. It is probable that the synchronous variety would have the better of it by 1 to 2 per cent at full load and add something more to the reasons for the change.

When no more relief can be obtained in the battle against bad power factor by procedure above outlined, the synchronous and static condenser become the logical subjects for consideration.

Here the relative efficiencies are at so great a variance that an analysis on the basis of yearly expense composed of capital charge, to cover interest on purchase price of apparatus and depreciation of same, plus losses at a price per kw-hr. must be made.

Referring to Fig. 8 will be found such a comparison

for synchronous and static condensers over rating from 60 to 1000 kv-a. and standard voltages of 220, 440, 550 and 2200 volts. Each equipment is charged in each respective capacity with 20 per cent of first cost, as capital charge per year and to this has been added the losses on basis of full load operation for 3500 hours per year at ¾ cents per kw-hr.

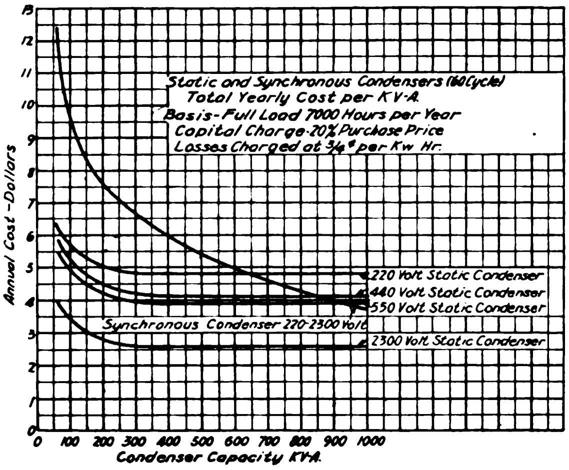

Fig. 9

On this basis it will be noticed that the static condenser in lower voltages is the cheaper device to own and operate in sizes approximately 500 kv-a. and below, and in case of 2200-volt apparatus the static device maintains its superiority up to capacities of about 1000 kv-a. If it were more reasonable to assume 24 hours per day operation on all days except Sundays and holidays as an equivalent basis of comparison and leave other assumptions untouched, results will be obtained as shown in Fig. 9 when the range of superiority of the static condensers may be said to have been increased 50 per cent making thereby the static device cheaper, in lower voltages in capacities of 750 kv-a. and below, and at 2200 volts in capacities well above the 1000-kv-a. rating.

Thus for cases where the condenser capacity is needed in amounts of approximately 750 kv-a. or less with a certainty of pretty constant operation and no demand for automatic voltage control, it is well to remember the static condenser as a worthy competitor of the synchronous device.

Conclusion

There is right now a peculiar pertinence to a review of a field so full of possibilities of reduction in delivered cost of electric power. Civilization's hope of the future lies in man's growing ability to produce per unit of time with resultant reduction of cost in terms of unit wage. Man's greatest aids in this battle are machines and power; which is growingly electric power.

Thus the delivered cost of electric power is becoming incorporated more and more widely into the cost of the necessities of life which is making the cost of electric energy a question of universal interest, and the engineer, if he maintains his expected measure of usefulness, must analyse his power producing and distributing plant today as never before, with the hope of new savings not only for his own and employer's good, but for general good as well.

It is hoped that the foregoing general facts may be fruitful to you in ideas which may aid in the broad problem before us all.

WHY THE CIVIL SERVICE COMMISSION STILL SEEKS APPLICANTS

Comment indicating wonder has been made in the press and elsewhere from time to time that the United States Civil Service Commission is still seeking applicants for examinations, notwithstanding the fact that the war is over and the Government force is decreasing. The Commission wishes to make clear its position in this matter.

On April 1, 1917, about 500,000 persons were employed in the Federal executive civil service. On November 11, 1918, the date of the signing of the armistice, at the height of the war expansion, this force had increased to about 850,000. It has now been reduced to about 650,000, and further reductions are steadily being made.

Although the Government force is constantly diminishing, the Commission must still seek applicants for some positions. The natural "turnover" in a force so large requires some appointments to fill vacancies, even though the total force is reducing. Fully three-fourths of all appointments are now made from "re-employment registers," which are made up of the names of employees dismissed because of reduction of force.

There are two conditions which necessitate some new appointments and, therefore, some announcements of examinations. One of these is that there are a number of technical positions to be filled from time to time for which re-employment registers do not provide eligibles. Because some offices are dismissing clerks, that fact does not help the Commission in its effort to fill a position of civil engineer, for example. The other reason is that the salaries now offered by the Government in the clerical grades are in many cases unattractive and dismissed employees decline to accept them and return to their homes. This leaves the re-employment registers not equal to the calls of the departments.

The Commission hopes that it may have the continued cooperation of the press in its effort to keep the Federal civil service up to a high standard of efficiency.

Alignment Chart For Circular and Hyperbolic Functions of a Complex Argument in Rectangular Coordinates

BY V. BUSH
Mass. Institute of Technology

Explanatory Note

THIS chart is based on the expansion formula:

$\sinh(x \pm j\,y) = \sinh x \cos y \pm j \cosh x \sin y.$

The two parts of the resulting expansion readily lend themselves to solution by an Alignment Chart. Thus Scale B is plotted to log. sinh x, and numbers used for grading are actual values of x. In the same way, Scale C is plotted to log. cos y, and numbers used for grading are actual values of y. The Scale E is plotted to the logs. of the products of Scales B and C, and the numbers these logs. represent are used for grading.

Thus any line drawn from x on Scale B to y on Scale C will intercept the value of $\sinh x \cos y$ on Scale E. In the same way, any line drawn between x on Scale A and y on Scale D will intercept the value of $\cosh x \sin y$ on Scale E. The first value plus or minus j times the second value gives the actual value of $\sinh(x \pm j\,y)$.

The values of y are given in quadrants, since it greatly facilitates the use of the chart. This must be remembered in handling functions and if the circular or imaginary power is expressed in radians, it must be reduced to quadrants for use in the chart, which can easily be done by multiplying by $\frac{2}{\pi}$.

By means of the expansion formulas, a very great variety and range of functions can easily be evaluated. For example:

$$\sinh 4\underline{/30^\circ} = \sinh(3.46 + j\,2) \text{ (in radians)}$$
$$= \sinh(3.46 + j\,.1275) \text{ (quadrants)}$$

Line from 3.46 on Scale B to 0.1275 on Scale C gives 16 on Scale E.

Line from 3.46 on Scale A to 0.1275 on Scale D gives 3.2 on Scale E.

Value of function is thus $16 + j\,3.2$, or:

$$\sinh 4\underline{/30^\circ} = 16 + j\,3.2$$

Value from tables: $15.8 + j\,3.15$, which checks well with this chart.

Formulas

$$\sinh(x \pm j\,y) = \sinh x \cos y \pm j \cosh x \sin y$$
$$\cosh(x \pm j\,y) = \cosh x \cos y \pm j \sinh x \sin y$$
$$\sin(x \pm j\,y) = \sin x \cosh y \pm j \cos x \sinh y$$
$$\cos(x \pm j\,y) = \cos x \cosh y \mp j \sin x \sinh y$$

Quadrant Formulas

e is an even integer, n is an odd integer

$$\sinh\{x + j(y \pm e)\} = -\sinh(x + jy)$$
$$\cosh\{x + j(y \pm e)\} = -\cosh(x + j\,y)$$
$$\sinh\{x + j(y \pm n)\} = +j\cosh(x \pm j\,y)$$
$$\cosh\{x + j(y \pm n)\} = +j\sinh(x \pm j\,y)$$
$$\sinh\{x + j(y + 1)\} = -j\cosh(x + j\,y)$$
$$\cosh\{x + j(y + 1)\} = -j\sinh(x + j\,y)$$

Directions

To find: $u + j\,v = \sinh(x + j\,y)$

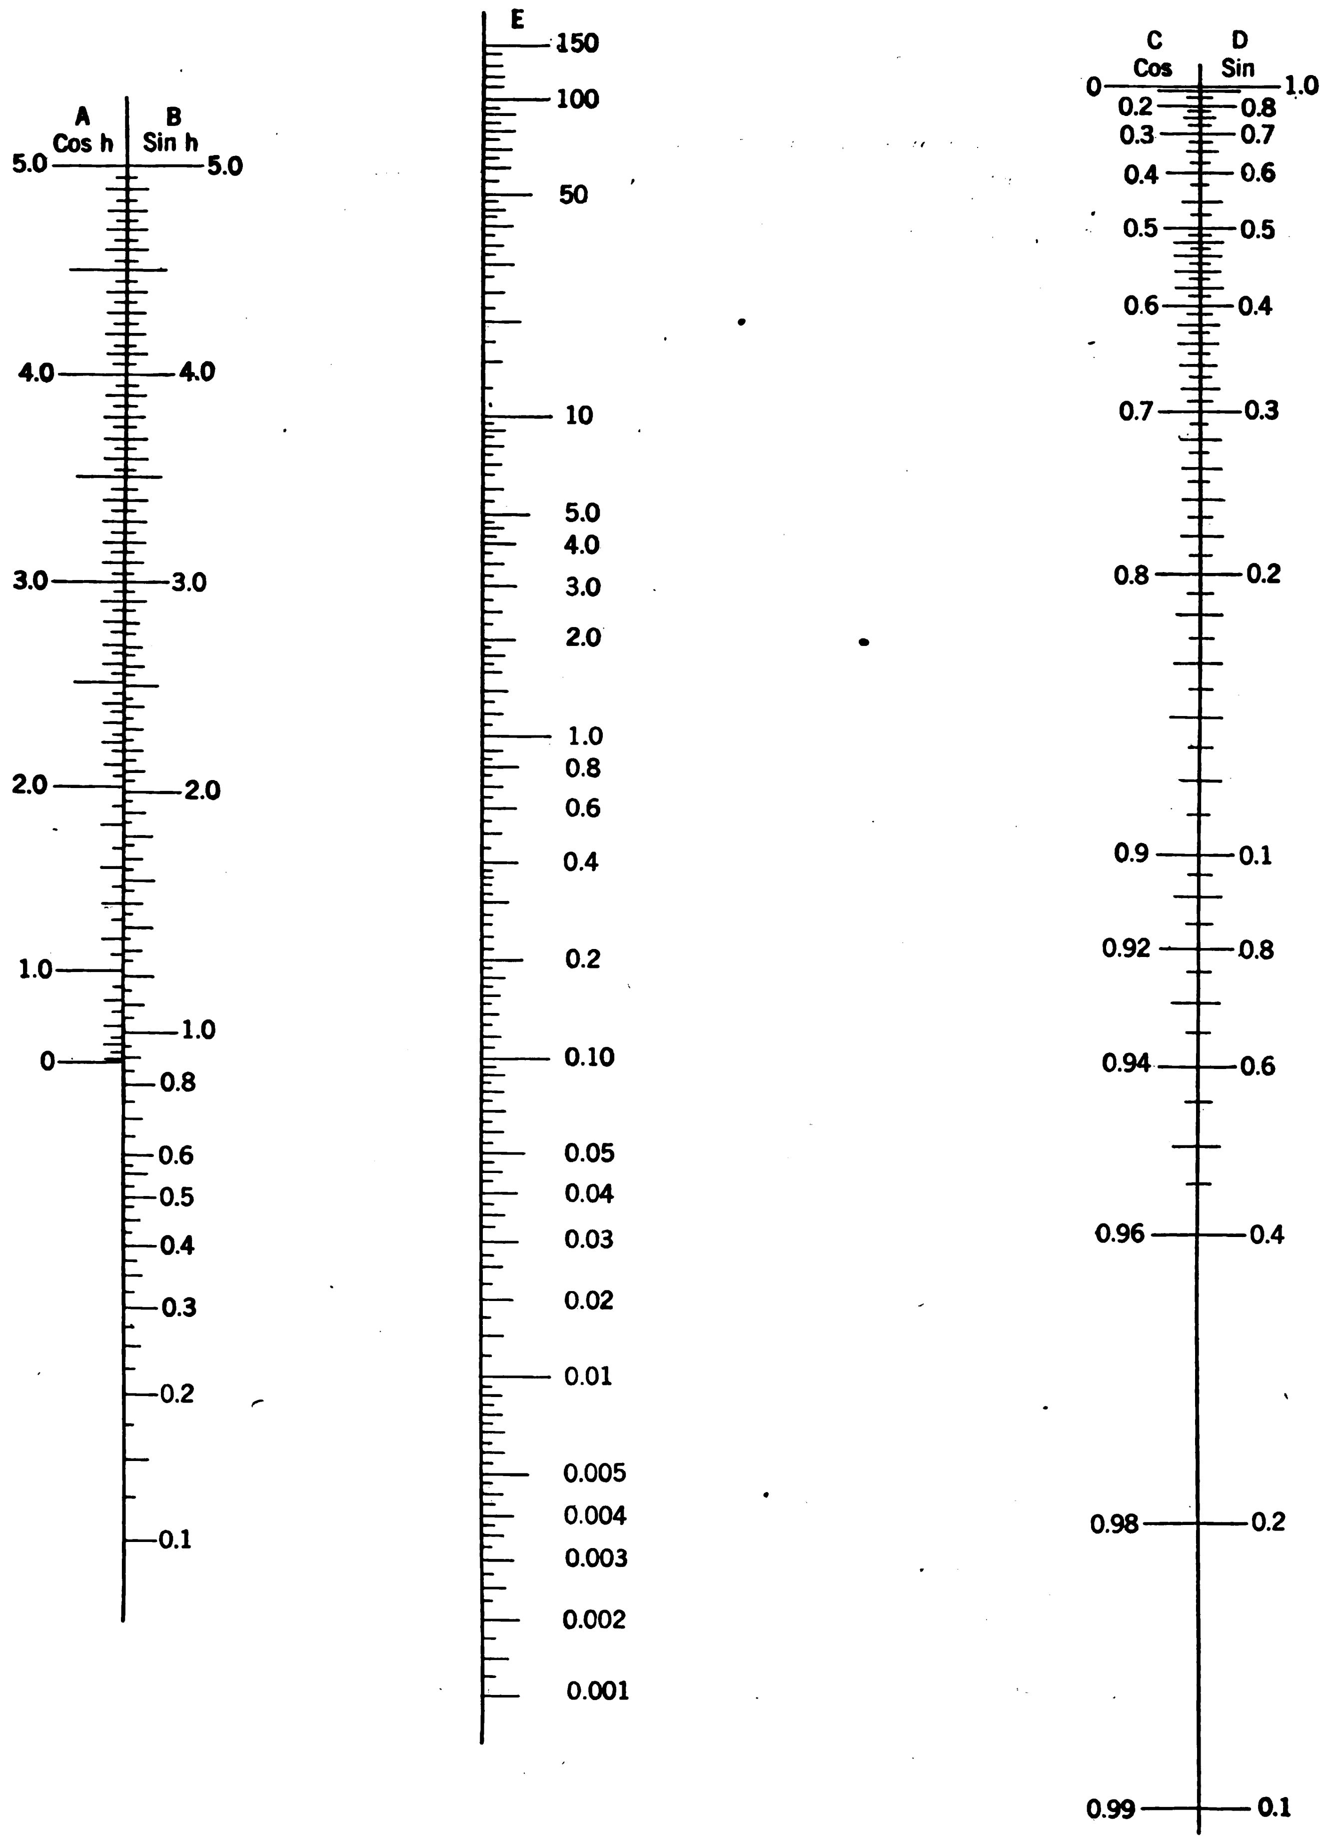
1. Express y in decimal parts of a quadrant.
2. Connect x on Scale B with y on Scale C by straight line. At intersection of this line with Scale E, read u.
3. Connect x on Scale A with y on scale C by straight line. At intersection on E, read v.

Similarly for other functions.

	u	v
sinh	$B\,C$	$A\,D$
cosh	$A\,C$	$B\,D$
sin	$D\,A$	$C\,B$
cos	$C\,A$	$D\,B$

THE TRANSMISSION OF MUSIC BY RADIO

Music can be transmitted by wireless in the same manner as speech or code signals. As an incidental result of research work on radio telephony at the Bureau of Standards, it has been shown that music can be transmitted by radio without loss of quality. The possibilities in this direction are great and very interesting. By this means a concert given in one place may be available to those living at a distance. Experimental concerts are at present being sent out on Friday evening from 8:30 to 11, by the Radio Laboratory of the Bureau of Standards, using a wave length of 500 meters. One way of transmitting music has been to place a phonograph so that the sound from it will pass into the radio transmitter. The Bureau of Standards has made an interesting improvement upon this method, which consists of substituting the carbon microphone, which is the mouthpiece of an ordinary telephone, for the vibrating diaphragm ordinarily used on the phonograph. As a result, the phonograph sound record produces direct variations of electric current in the telephone apparatus instead of producing sound, thus while no sound is heard where the phonograph record is being played, the music is easily heard by those at the distant receiving stations.



ALIGNMENT CHART FOR CIRCULAR AND HYPERBOLIC FUNCTIONS OF A COMPLEX ARGUMENT IN RECTANGULAR COORDINATES

The Design of Air-Core Inductance Coils of Minimum Weight for a Given Inductance and Resistance

BY C. O. GIBBON
Research Engineer, Fessenden Engineering Laboratory.

ANYONE familiar with the design of air-core inductances knows, that for a given resistance, the size and weight of the coil rapidly increase as the inductance is increased. Though the increased cost due to this increase in weight may not be of great importance, it is evident in many types of apparatus in which such coils play an essential part, as in portable radio sets, that both weight and size must be reduced to the minimum possible.

To calculate the inductance and resistance of any air-core inductance coil, given its dimensions, the size of wire, and the number of turns, is a simple matter; but to design a coil which shall have any preassigned values of resistance and inductance, with this added condition, that the coil have minimum possible weight, is a problem which ordinarily presents no little difficulty and necessitates numerous trial calculations.

Any cut and try method of design is both unsatisfactory in results and wasteful of time. It was for the purpose of determining a simple and exact procedure in the design of such coils that the writer recently carried out an analytical investigation of the problem. The results of that analysis render it possible to read directly from curves the dimensions and weight of the lightest air-core inductance coil having any specified inductance and resistance, and by the use of simple formulas, to determine at once the number of turns, manner of winding, and size of wire to be used. The theoretical derivation of these curves and formulas, together with an outline of the proper procedure in their use, in the main, form the subject of the present paper.

The General Inductance Formula

The inductance of a circular coil of rectangular cross-section (see Fig. 1) having an air-core, is given by Maxwell to be:

$$L = 4\,\pi\,a\,N^2 \left[\left(\text{logh}.\ \frac{8\,a}{R}\right) - 2\right] \text{ centimeters} \quad (1)$$

where

L = Inductance in centimeters.
N = Total number of turns in coil.
a = Mean radius of coil in centimeters (see Fig. 1)
R = Geometrical mean distance of the transverse section of the coil from itself.
logh. stands for the Naperian logarithm.

For any value of the ratio $b : c$, where b is the axial length and c is the radial depth of the coil (see Fig. 1), both in centimeters, Maxwell further shows that

$$R = k'\,(b + c) \quad (2)$$

where (k') is a constant of proportionality. Equation (1) then becomes

$$L = 4\,\pi\,a\,N^2 \left[\left(\text{logh}.\ \frac{8\,a}{k'\,(b + c)}\right) - 2\right] \text{ centimeters} \quad (3)$$

General Outline of Theory

Before entering further upon the details of the analysis it may be illuminating to outline, in a general manner, the steps to be taken.

If we assume a wire of which the length (1) and the resistance R are fixed, the cross-section of the wire, its weight, and the product $(4\,\pi\,a\,N)$ are also fixed. This wire we may wind into any circular coil of rectangular cross-section we choose: for each manner of winding a unique value of inductance will result. Our problem then resolves itself into one of determining such relations between a b and c as will, for the given wire, insure maximum possible inductance.

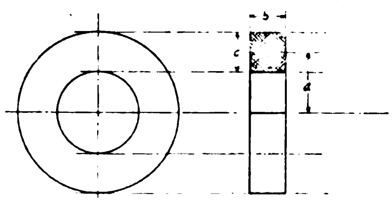


Fig. 1

The mathematical solution of this problem divides itself into the two following steps:

1. We may hold a constant, thereby fixing the number of turns N and the transverse area $b\,c$ of the coil, and determine that ratio $b : c$ which will give maximum inductance.

2. Keeping the ratio $b : c$ so obtained we may allow a to vary, thus arriving at that ratio $a : b$ for maximum inductance.

These ratios determined we may derive the curves and the auxiliary formulas necessary for the complete design.

Step 1.

As stated above our fixed values are first a, R, N and

$$b\,c = k'' \quad \text{whence } c = \frac{k''}{b} \text{ cm.}$$

also

$$4\,\pi\,a\,N^2 = K \text{ (a constant)}$$

Then

$$\text{logh}.\ \frac{8\,a}{k'\,(b + c)} = \frac{K}{b + c} = \frac{k}{b + \dfrac{k''}{b}} \text{ numeric}$$

Substituting these values into equation (3) it becomes

$$L = K\left[\left(\text{logh.}\,\frac{k}{b+\frac{k''}{b}}\right) - 2\right] \qquad \text{cm.}$$

$$= K\left[\left(\text{logh.}\,k - \text{logh.}\,b + \frac{k''}{b^2}\right) - 2\right] \qquad \text{cm.}$$

Differentiating with respect to b and equating to zero we obtain

$$\frac{dL}{db} = -K\left(\frac{1}{b+\frac{k''}{b^2}}\right)\left(1 - \frac{k''}{b^2}\right) = 0$$

or

$$\left(\frac{b}{b^2+k''}\right)\left(\frac{b^2-k''}{b^2}\right) = 0$$

Of the two factors on the left one must vanish. It is obvious that for positive values of k'' the term $\frac{b}{b^2+k''}$ vanishes only if k'' becomes infinite.

Hence we must have

$$\frac{b^2-k''}{b^2} \quad \frac{b^2-bc}{b^2} = 0$$

whence $b^2 - bc = 0$

or finally $b = c$ cm.

This tells us that the coil of minimum weight for given inductance and resistance is square in cross-section.

If $b = c$ Maxwell gives $k' = 0.2235$ and equation (3) reduces to

$$L = 4\pi a N^2\left[\left(\text{logh}17.9\,\frac{a}{b}\right) - 2\right] \quad \text{centimeters} \tag{4}$$

Step 2

Again referring back to the general outline we shall allow a to vary, while our constants are

$$4\pi a N = k_2$$

and

$$2\pi a N = k_2'$$

from which

$$N = \frac{k_2'}{2\pi a} = \frac{k_3}{a} \qquad \text{turns}$$

The size of the wire being fixed evidently necessitates that

$$b\,c = b^2 = k_5 N = \frac{k_4'}{a} \qquad \text{cm.}^2$$

or

$$b = \frac{k_4}{\sqrt{a}} \qquad \text{cm.}$$

Substituting these values into equation (4) and placing $17.9 = k_1$ it becomes

$$L = k_2\frac{k_3}{a}\left[\left(\text{logh}\,\frac{k_1 a^{3/2}}{k_4}\right) - 2\right] \qquad \text{cm.}$$

Differentiating with respect to a and equating to zero

$$\frac{dL}{da} = -\frac{k_2 k_3}{a^2}\left[\left(\text{logh}\,\frac{k_1 a^{3/2}}{k_4}\right) - 2\right]$$

$$+ \frac{k_2 k_3}{a}\left(\frac{k_4}{k_1 a^{3/2}}\cdot\frac{k_1}{k_4}\cdot a^{1/2}\right)\frac{3}{2} = 0$$

$$\text{logh}\,\frac{k_1 a^{3/2}}{k_4} - 3.5 = 0$$

$$\frac{k_1 a^{3/2}}{k_4} = \frac{k_1 a^{3/2}}{b\,a^{1/2}} = k_1\,\frac{a}{b} = \epsilon^{3.5} \qquad \text{numeric}$$

from which $a = 1.85\,b$ cm.

Substituting this relation into equation (4) it reduces to our final formula

$$\left.\begin{array}{lll} & L = 18.85\,N^2 a & \text{centimeters} \\ \text{when} & b = c & \text{centimeters} \\ \text{and} & a = 1.85\,b & \text{centimeters}\end{array}\right\} \tag{5}$$

The writer up to this point has merely retraced a path long ago explored by Maxwell (see "Electricitiy and Magnetism," Vol. II, pp. 345-346, p. 706) who has already pointed out the preceding relations between a, b and c. These relations, however, have been here derived in a manner much more easily grasped, and with far more detailed steps than in their treatment in the classic work of Maxwell. The derivation is therefore given for the sake of its simplicity and for the clearness and completeness of the paper as a whole.

But while the relations in (5) are not new, I now propose to point out and derive a series of relations which, combined with the above are developed into a system of design that to the best of my knowledge is entirely original.

Derivation of Auxiliary Formulas

With these, our fundamental relations, in mind we may consider a as the independent variable, and allow it to assume any other value $a' = n\,a$ while the inductance L is held constant, the other variables will be seen to change according to the following governing relations:

$$\left.\begin{array}{ll} \text{if} & a' = n\,a \\ \text{then} & b' = n\,b \\ & c' = n\,c \\ & L' = L \\ & d' = n^{3/2} d \\ & A' = n^{3/2} A \\ & R' = \dfrac{R}{n^2} \\ & \gamma' = \dfrac{\gamma}{n^{3/2}} \\ & W' = n^3 W \end{array}\right\} \text{Relations for constant inductance } L \text{ but variable mean radius } a. \tag{7}$$

If on the other hand we treat L as the independent variable but hold a constant then:

$$\left.\begin{array}{lll} \text{if} & L' & = m\,L \\ \text{then} & a' & = a \\ & b' & = b \\ & c' & = c \\ & N' & = N\sqrt{m} \\ & l' & = l\sqrt{m} \\ & d' & = \dfrac{d}{m^{1/4}} \\ & A' & = \dfrac{A}{\sqrt{m}} \\ & R' & = m\,R \end{array}\right\} \begin{array}{l}\text{Relations for constant} \\ \text{mean radius } a \text{ but variable} \\ \text{inductance } L.\end{array} \quad (8)$$

Where a = Mean radius of coil in centimeters.
b = Axial length of coil in centimeters.
c = Radial depth of coil in centimeters.
n and m = any multiplier.
d = Diameter of wire (bare copper) in centimeters.
A = Cross-section of wire in circular micrometers.
R = Total d-c. resistance of coil in ohms.
L = Inductance of coil in centimeters.
N = Total number of turns in coil.
γ = Resistance of wire per centimeter.
l = Total length of wire in centimeters.
W = Total weight of coil (copper) in pounds.

Of particular immediate importance are the two relations of (**8**)

$$L' = m\,L$$
and
$$R' = m\,R$$

Dividing, we have

$$\frac{L'}{R'} = \frac{m\,L}{m\,R} = \frac{L}{R}$$

That is, for constant mean radius a the resistance varies directly as the inductance, or the ratio for any given mean radius is fixed and is a function of a

$$\frac{L}{R} = K\,(a)$$

If now, a is allowed to vary while L remains constant, then from (**7**)

$$K\,(a') = \frac{L'}{R'} = \frac{L}{R}\,n^2 = n^2\,K\,(a) \qquad (\mathbf{10})$$

If we assume $a = 1$
then since $a' = n\,a$
we have $a' = n$
whence $K\,(a') = a'^2\,K\,(l)$
or dropping the primes $K\,(a) = a^2\,K\,(l)$ (**11**)

Let us now calculate $K\,(l)$.

If $a_1 = 1$ cm. then $b_1 = c_1 = 0.541$ cm.
Take $L_1 = 1$ millihenry $= 10^6$ centimeters, and solve for (R).

By equation (**5**)

$$N_1 = \sqrt{\frac{L_1\,(\text{cm})}{18.85\,a_1}} = \sqrt{\frac{10^6}{18.85}} = 230.5 \text{ turns}$$

The number of turns per layer η_1 is, since $b = c$

$$\eta_1 = \sqrt{N_1} = 15.5 \text{ turns per layer}$$

The diameter of the wire d_1 is

$$d_1 = \frac{b_1}{n_1} = \frac{0.541 \times 10}{15.5} = 0.349 \text{ millimeters}$$

The resistance of copper wire at 20 deg. cent. is 228.5 ohms per circular micrometer, per centimeter length. Hence

$$R_1 = \frac{2\,\pi\,a_1\,N_1 \times 228.5}{(349)^2} = \frac{2\,\pi \times 230.5 \times 228.5}{(349)^2} = 2.715 \text{ ohms}$$

Then $K\,(l) = \dfrac{L_1}{R_1} = \dfrac{1}{2.715} = 0.368$ numeric

Whence by (**11**) $K\,(a) = 0.368\,a^2$ (**12**)

Taking the weight of copper as 0.01967 pounds per cubic centimeter, the weight of this unit will be

$$W_1 = 2\,\pi\,a_1\,b_1^2 \times 0.785 \times 0.01967$$
$$= 2\,\pi \times 0.541^2 \times 0.785 \times 0.01967 = 0.0284 \text{ lb.}$$

Here the factor 0.785 is the ratio of the area of a circle to the area of the circumscribed square and enters because we are filling a square section with circular wires.

The weight of any coil will be by (**7**)

$$W = 0.0284\,a^3 \text{ pounds} \qquad (\mathbf{13})$$

Combining equations (**12**) and (**13**) gives

$$W = 0.0284\,\frac{K\,(a)}{0.368}\,a = 0.0772\,a\,K\,(a) \text{ pounds} \qquad (\mathbf{14})$$

Curves Convenient in Design

Collecting the important relations we have

$$b = c \text{ centimeters} \qquad (\text{I})$$
$$a = 1.85\,b \text{ centimeters} \qquad (\text{II})$$
$$L = 18.85 \times 10^{-6}\,N^2\,a \text{ millihenrys} \qquad (\text{III})$$
$$\frac{L\,(\text{millihenrys})}{R\,(\text{ohms})} = K\,(a) = 0.368\,a^2 \text{ numeric} \qquad (\text{IV})$$
$$W = 0.0284\,a^3 \text{ pounds} \qquad (\text{V})$$
$$= 0.0772\,a\,K\,(a) \text{ pounds} \qquad (\text{VI})$$

Equations (IV) and (VI) enable us to plot curves from which the mean radius and weight of a coil having any assigned values of inductance and resistance may immediately be read. Such a set of curves of W and a plotted against $K\,(a)$ is shown in Fig. 2. The calculated values from which these curves were plotted are given in Table I. In using these curves it must be remembered that the values read are only approximate. The actual dimensions must be varied slightly to suit standard gage wire, and the insulation thickness must, if great accuracy is required, be taken into account.

Finally, the value of inductance should be checked by the original formula,

$$L = 4\,\pi\,a\,N^2 \left[\left(\text{logh}\,\frac{8\,a}{\mathcal{R}} \right) - 2 \right] 10^{-6} \text{ millihenrys} \tag{15}$$

in which, so long as b and c are approximately equal,

$$\mathcal{R} = 0.2235\,(b + c)$$

Procedure in Design

Having given the inductance L in millihenrys, and the resistance R in ohms, the mean radius a may at once be read off the curves, Fig. 2, or calculated by equation (IV)

$$a = 1.648 \left(\frac{L}{R} \right)^{1/3} \quad \text{centimeters}$$

Then $\quad b = c = 0.541\,a \quad$ centimeters

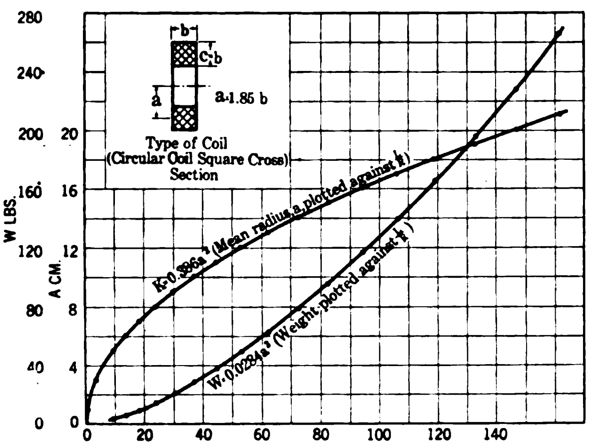

Fig. 2—Curves of Weight and of Mean Radius Plotted Against the Ratio L/R for Air-Core Coil of Minimum Weight and Maximum Inductance

Solid Copper Wire

With a and L known, next determine the number of turns from (III)

$$N = 230.3 \sqrt{\frac{L\ (\text{m. h.})}{a\ (\text{cm.})}} \quad \text{turns}$$

Since the coil is of square cross-section the number of turns per layer (V) is

$$v = \sqrt{N} \qquad \text{turns per layer}$$

The diameter d of the wire can now be found.

$$d = \frac{b}{v} \qquad \text{centimeters}$$

The weight will be given by V or may be read from the curves Fig. 2.

In general N as calculated will not be a perfect square. To meet this we may either change the cross-section of the coil slightly or vary the number of turns. Thus suppose we obtain $N = 242$ turns: the coil may be wound with 240 turns in 16 layers of 15 turns per layer. Likewise, it is improbable that d as solved will correspond to the diameter of any standard gage wire. Simply select the next larger standard gage.

Thus the complete dimensions of the coil, the number of turns, and the size of the wire have been determined by a series of simple steps, each containing but one unknown quantity. It but remains to check the inductance by equation (**15**), the resistance by the formula

$$R = a\,\pi\,a\,N\,\gamma \qquad \text{ohms} \tag{16}$$

and the solution for the coil of minimum weight for the given inductance and resistance is complete.

Coils Wound with Stranded Conductors

For the most part inductance coils are designed to operate either in alternating- or oscillating-current circuits. If the design of a coil shows that a large wire must be used, then the question of the increase of the

TABLE I

a cm.	$K = L/R = 0.368a^3$ numeric	$W = 0.0284a^3$ lbs.
1	0.37	0.03

21	162.20	263.00

a-c. resistance over the d-c. resistance immediately becomes important. As is well-known, this resistance ratio rises rapidly as the size of wire is increased, but may be greatly reduced by employing stranded conductor, the strands, of course, being insulated. In fact, when stranded conductor is used, if means be taken to insure an equal distribution of current in all strands, the ratio may be reduced to that corresponding to that size of wire composing the strands.

Round wires strand best in progressive squares of seven, *i. e.*, 7, 49, 2401, etc.—six conductors spiraled about one as a center in the case of seven strands, or, if 49 strands are used, seven conductors of seven strands each are made up with, say, a left hand spiraling and six of these conductors spiraled about the seventh with right hand spiraling.

If it be found necessary to use stranded conductor then, due to the space factor, the dimensions of the coil are considerably altered. The system of design which I have outlined may, by a very simple expedient, be

made to apply directly to coils wound with stranded conductor.

Suppose that a coil first wound of solid wire has a resistance R_1 and an inductance L_1. Let us now replace the solid wire with a seven-strand conductor occupying exactly the same space. The number of turns, length of conductor and dimensions of the coil will remain the same and hence the inductance will be unaltered. The resistance, however, is increased as follows. Since the diameter of each strand is one-third and the area, one-ninth that of the original solid wire, the resistance R_2 of the coil wound with such a stranded conductor will be

$$R_2 = \frac{9}{7} R_1$$

From this it is obvious that we may use for coils of stranded conductors either the curves or method of calculation given, merely by multiplying our ratio $\frac{L}{R}$ by $\frac{9}{7} = 1.286$ and proceeding as before, but basing our work on this new ratio.

For a solid wire $K_1 = \frac{L}{R}$

For seven-strand conductor $K_7 = 1.286 \frac{L}{R}$

For a 49-strand conductor $K_{49} = 1.653 \frac{L}{R}$

If desired an additional factor may be introduced to care for the space factor occasioned by the added insulation.

Control of Current Distribution among Strands

For the material in the discussion of this topic the writer is greatly indebted to Mr. D. R. Price of the Fessenden Engineering Laboratory.

It has already been mentioned that if the current in a stranded conductor be made to divide itself equally among the strands then the ratio of a-c. to d-c. resistance for the whole conductor is reduced to that of a single strand. Mere stranding, though giving better results than a solid wire, is, however, not sufficient to insure this desirable condition. Special methods must be resorted to.

Since skin effect usually becomes of importance only at frequencies above one hundred cycles, and for large wires, we need only consider the case where the reactance is many times as great as the resistance, *i. e.*, where the power component of the current is negligible compared with the reactive component.

Since the purpose of controlling the current distribution among the strands is to reduce the effective resistance, no end is served by adding resistance in series with any strand taking more than its share of current. Moreover, as the resistance drop is so small compared with the reactive drop, a resistance many times that of the strand would be necessary to produce any appreciable regulating effect. Obviously, the thing to do is to increase the inductance of any strand taking an excess of current, and to do this with as small an increase in the resistance of the strand as possible.

This may be quite simply accomplished by any one of several methods. The method which first suggests itself is to lead each strand separately to a terminal board and to connect in series with each a small independent inductance coil. These coils are then varied to equalize the current in the strands. This method is open to the objection that, since the small coils must set up their own regulating flux, a considerable number of turns may be required to produce the proper current distribution and an appreciable resistance be thereby added to that of the strand. A better method is that of tapering off the strands. That is, those strands which take an excess of current are lengthened out and given added turns about the coil itself. By this means the added turns are linked by the entire flux of the coil itself and a far greater regulating effect thus obtained with much less added resistance than by the preceding method.[1]

A Slight Digression from the Subject

In following any path of research one comes constantly upon cross-paths which enticingly tempt one to explore them and learn what point of interest may be hidden just out of sight around some turn. Thus is one often led to digress and explore a field. Since the writer takes particular pleasure in exploring these by-paths, he wandered along many such while following the research which resulted in the writing of this paper. One of these led to an interesting discovery that I shall now describe.

The coils whose design has been herein outlined may be considered coils of maximum efficiency. In many types of electrical apparatus maximum efficiency obtains when certain quantities reach equality. Thus an electric motor has maximum efficiency when its fixed and variable losses are equal. It was suggested by Prof. Reginald A. Fessenden that in these maximum efficiency coils the reluctance of the flux path through the coil should equal the reluctance of that portion of the path external to the coil.

This I verified mathematically as follows.

For the inductance of circular coils of square cross-section Weinstein has derived the formula (see Bulletin of Bureau of Standards, Vol. 5, No. 1, pp. 46 & 49).

$$L_w = L_w - \Delta_2 L \qquad \text{centimeters}$$

where

$$L_w = 4\,\pi\,a\,N^2 \left\{ \left(1 - \frac{c^2}{24\,a^2}\right)\left(\operatorname{logh} \frac{8a}{c}\right) - 0.03657\,\frac{c^2}{a^2} - 1.194914 \right\} \text{cm.}$$

1. Both of the methods here described and several others for accomplishing the same result are fully covered in patents granted to Mr. D. R. Price. See U. S. Patent No. 1,213,689.

and

$$\Delta_2 L = 4\,\pi\,a\,N \left(\text{logh} \frac{D}{d} - 0.13806 - E \right) \text{ cm.}$$

Here

N = Number of turns in coil.

a = Mean radius of coil in centimeters.

c = Length of one side of square cross-section in centimeters.

D = Diameter of covered wire.

d = Diameter of bare wire.

E = A term which takes into account the difference in the mutual inductances of the separate turns of wire on one another when the wire has a round section from what the mutual inductance would be if the wire were of square section and no space was occupied by the insulation. We shall here take E corresponding to a coil having ten layers of ten turns per layer. For this coil $E = 0.01713$ (see Bulletin of Bureau of Standards, Vol. 5, No. 1, p. 50).

For maximum efficiency coils as already shown

$$a = 1.85\,c$$

We shall take $\frac{D}{d} \doteq 1$ and $\text{logh}\frac{D}{d} = 0$ $N = 100$

Substituting these values into the above equations we find

$$L_u = 4\,\pi\,a\,N^2\,(1.54321)$$

$$\Delta_2 L = 4\,\pi\,a\,N\,(0.15519) = 4\,\pi\,a\,N^2\,(0.001552)$$

$$L = 4\,\pi\,a\,N^2\,(1.54476)$$

If

ϕ = Flux (Maxwells)

M = Magnetomotionforce (Gilberts)

$\mathcal{P}$ = Permeance (c. g. s. units)

λ = Linkages

$\mathcal{R}$ = Reluctance (Oersteads)

we have

$$\phi = M\,\mathcal{P}$$

$$\lambda = M\,\mathcal{P}\,N$$

$$M = 4\,\pi\,N\,i \quad \text{if } i \text{ is in abamperes}$$

$$\therefore \lambda = 4\,\pi\,N^2\,\mathcal{P}\,i$$

$$\frac{d\lambda}{dt} = 4\,\pi\,N^2\,\mathcal{P}\,\frac{di}{dt}$$

$$L = \frac{\frac{d\lambda}{dt}}{\frac{di}{dt}} = 4\,\pi\,N^2\,\mathcal{P}$$

$$\mathcal{P} \quad \frac{L}{4\,\pi\,N^2}.$$

That is, the permeance of the magnetic circuit of a coil equals the inductance divided by $4\,\pi\,N^2$.

Hence for the coil under consideration

$$\mathcal{P} = 1.54476\,a$$

$$\mathcal{R}_t = \frac{1}{1.544762} = \frac{0.646}{a}$$ (reluctance of total magnetic circuit)

The reluctance through the coil is

$$\mathcal{R}_i = \frac{c}{\pi\left(\frac{29-c}{2}\right)} = \frac{0.323}{a}$$

$$\frac{\mathcal{R}_i}{\mathcal{R}_t} = \frac{0.323}{0.646} = 0.5$$

Thus we have found that the reluctance of the total magnetic path is twice that of the portion of the path through the coil, or that the reluctance through the coil equals the reluctance of the remainder of the circuit, for these maximum efficiency coils.

THE PHENOMENA OF RADIO TELEGRAPHY AND TELEPHONY

Communication by means of electricity without wires has progressed very rapidly during the last few years, and has probably been given more consideration by the general public than almost any other scientific subject. It is, nevertheless, a fact that due to the somewhat inaccurate and misleading newspaper accounts which have appeared from time to time dealing with the principles of radio communication and which have been apt to surround the whole matter with an air of mystery most people believe that the principles underlying wireless transmission are not very well-known. On the contrary, radio communication is a natural effect following well-known causes. With the object of giving a concise and easily understood explanation of the principles underlying radio communication, a lecture was given at the Bureau of Standards during May of this year, in which the whole subject was thoroughly discussed in a way easily understood by all. The similarity between various forms of wave motion, of which radio communication is one, was described and illustrated. Copies of this lecture will be available for distribution to those interested.

The Study of Mentality in Industry

BY H. W. JORDAN

Semet-Solvay Co., Syracuse, N. Y.

THE Study of Mentality in Industry, in which the Engineering Foundation has done some preliminary work, marks a new appreciation of the responsibilities which confront us. "Civilization as we know it today is due mainly to the engineer or applied scientist. As a profession, we are largely responsible for present conditions and therefore we should do our part in solving such problems as exist, and in helping to direct aright the tendencies of the day. We have a duty to ourselves to our profession, to society, and to our successor,—and we must perform it," said George F. Swain, ex-president of the American Society of Civil Engineers.

It is a startling paradox of our times that the brain workers, the intellectual classes, who have high school education and beyond, are a decidedly minor force as citizens; while the manual workers are a powerful, swiftly growing civic force. We engineers and our associated brain workers create the industries, direct their operation and forecast their future. But as a factor in citizenship and social life, we are almost ciphers. One reason of this is that we deal with *causes*, with the foundation and substance of material and social structures. The public is not interested in a subway or in a great building under design or construction. It rarely sees these works of the engineer until the job is finished and the opening reception is held. Hence the public neither appreciates nor understands the tremendously important part which engineers play in economic and social life. The time is at hand for us to teach them.

The press, which fashions public opinion, deals with effects. The public is dazzled by sensational news, by stories of the abnormal and the gross, and by the incessant game of politics, rather than the science of government. The press deals with finished things, with effects. If a great bridge falls, the press gives it columns on the front page, but when the New York subway and the Hudson tubes carry hundreds of millions of people without the loss of a single life, that engineering achievement receives not a single line. Public opinion is based on a shaky foundation of distorted, sensational description of events, which are effects. We engineers need to build a new order of public opinion, evolved from social scientific research and based upon fundamental facts, which are causes. Our field for this public opinion is the intellectual public, the brain workers.

In marked contrast to the brain workers, there stand the manual workers of every sort. Directly and indirectly, the manual workers, to the extent of at least 35 per cent of our people, are organized and are adroitly and aggressively led along distinct lines of class purposes. By their numbers and the mere volume of their argument, they carry conviction, and secure strikes and other direct action, which prove disastrous to them and to all of us, because their efforts are directed against effects, rather than toward the discovery and scientific utilization of economic laws and natural energies. Most strikes are a mere infuriated mopping up of the floor, instead of turning off the faucet, from which the flood proceeds.

And our own action in government and in citizenship is mainly such a mad mopping up of the floor. Bernard Shaw has truly said that Americans "are the greatest post mortem nation in the world." We spend millions upon congressional, state and city "investigations," which produce little result other than to furnish front page news which is promptly forgotten.

In recent years, we have begun to learn that the life of mankind is regulated by laws as definite and knowable as the law of gravity. The century before us is destined to be one of marvelous extension in the knowledge of the mind and the application of that knowledge to social life, to government and to industry. The engineers and their industrial corporations which attain the greatest achievements in the twentieth century, will be those who most quickly learn the new sciences of the mind, and apply them promptly and effectively to engineering and to citizenship.

Hollander says: "Starting from a rude social order wherein bare and uncertain existence was the most that man could wrest from nature, society has attained an incredible economic productivity by the development of intellectual force and manual dexterity, by the more efficient arrangement of its own powers, and most of all by the discovery and utilization of natural energy." The economic era upon which we are entering, is to be characterized by similar discovery and utilization of the natural energies of the mind. The Study of Mentality in Industry by the Engineering Foundation and National Research Council, if rightly directed can be developed by the organized American engineers into an agency of prodigious benefit to the engineering industries, to government and to social life.

The work should be early extended to include subjects of international scope. In addition to specific investigations, such as those already undertaken, the study should bring the attention of American engineers to great fundamental world problems of economics, ethnology and sociology. It should be interpreted largely in terms of more efficient living, the production and distribution of food and the raw materials of clothing, the provision of adequate, comfortable housing, the maintenance of working and living conditions which assure contentment, and the expansion of the lives of brain workers into broader activity in the intellectual and spiritual fields of literature, music, art and religion. Above all else, prompt and profound attention should be given to the study of agriculture,

in its relation to industrial and social life. Equally profound thought should be devoted to racial studies, directed toward the improvement and perpetuation of the human race and the protection of the racial interests of the intellectual classes, who are now being sacrificed to industry and property. We can make a good beginning of these researches by reading Madison Grant's "The Passing of the Great Race," and Lathrop Stoddard's "The Rising Tide of Color." Our study of public opinion should include Walter Lippmann's "Liberty and the News."

The bulletins of the Foundation, which summarize these studies, should be widely distributed in pamphlet form, and should be published in all engineering and technical journals. They should then be extended to great weekly journals, like the *Saturday Evening Post*, and *Christian Herald*, *The Outlook* and similar publications which reach intellectual people. Step by step, these mental researches of the American Engineering Societies should be spread before the entire reading public, to the end that the brain workers and all thinking people are consolidated into a social force which moves steadily forward by the light of scientific facts and the newly disclosed laws of mentality, rather than by their present guidance of sensational news and a press inspired by political and selfish class bias. Like the Pilgrim at Plymouth Rock, all our people should work and live "for ye generale good of ye colonie."

If the engineers direct their study of mentality and social science along this program, they can perform their duty to society and truly succeed in "directing aright the tendencies of the day." Let us illustrate the possibilities of such social studies, by citing some of the most important problems, which we can solve by the application of scientific research and experimentation, the medium by which we evolved our engineering industries.

1. The changed condition of the land, of agriculture and our homes, is perhaps the most fundamental subject which requires study and correction. Our nation has shifted from an agricultural, home-farm-owning population to a city-dwelling, home-renting, industrial population. Our engineering industries have caused this shift. The land and agricultural problem of the world is truly vital. In Mexico, the incessant revolution is primarily a land question, a fight of the people to get the land, from which to make their living. Japan seeks more land and increased natural resources to relieve her population pressure. We in the United States have a serious land problem. It is a recently recognized law that as a nation declines in agriculture and the people give up ownership of their farms and move to the cities to gain their livelihood by commerce or industry, they become effeminate. Men and women copy each other's clothes. The people lose their individuality, their personal initiative, their military spirit and their home instinct. They become a metropolitan conglomerate. The birthrate declines, because husband and wife are absorbed in material selfishness, rather than in home, parenthood and the love of children. They lose their finer intellectuality. The drama, art, music and literature decline, the religion dies. When religion dies in a nation, as it is doing in America today, that nation dies. Babylon, Greece and Rome dominated the world, so long as their people lived on their own land and centered their lives in their homes, their families and their religion. They perished at the hands of mediocre barbarians, skilfully and aggressively led, who overwhelmed and conquered these seemingly prosperous people, when they became enervated by materialistic city life and the decay of their religion.

One of the most wicked and race-destroying features in this shift of ours from the land and the open country to the congested city, is the oppressive condition, whereby families with children, even with one little baby, are unable to find houses or apartments which they can rent as homes. This glaring sacrifice of the continuance of the race to the material interests of property should convince us of the need of organized scientific activity by the brain workers, in their own racial defense, that they may have their homes and rear their children. We are so saturated with the grossly selfish spirit, that "it doesn't matter what happens, so long as it doesn't happen to us," that we folks of the engineering industries are undertaking no effective action to assure the next generation an opportunity to enter the world. Unless there be abundant and attractive homes, with happiness and contentment for the next generation, there will be no brain workers to direct the industries we have created, and our plants will fall in ruins, like New York or New England abandoned farm homesteads. Property without people is worthless. Property without people is a wilderness, a desert.

2. Formerly the child learned life by living. The household arts which used to supply home technical training have been almost completely superseded by factory manufactured food and clothing. Water, light, and fuel for cooking are delivered to our homes through pipes or over wires, displacing the old oaken bucket and the chain pump, the bucksaw and the woodpile, and the kerosene lamp. The waterwheel at the brook, the wind-wheel on the woodshed, the figure 4 trap and the muzzle loading shotgun have been supplanted by Mary Pickford and Charlie Chaplin, witnessed seated, in a dark room. Healthful play at home is rarely possible, for there is neither room nor play space. Play is transferred to city parks, where unmarried women of advanced years are hired to teach children to play.

The schools of former days and the long summer vacation were designed for New England and New York village and farm life. The education of that time was adequate, and the training in practical life

which children received from their daily work at home produced self-reliant, resourceful Yankees. The industrial changes of the past thirty-five years have robbed children of active experience in life and have given them passive, commercialized amusement instead.

Our engineers' study should devise means for bringing the children back into touch with agriculture, industry and civics. This can easily be accomplished by conducting the children on study trips to all these activities of daily life and using them as the basis of broad, liberal education. If the instruction include the relation of the entire world to local daily life, if the training be directed literally to the education, the drawing out, of the child's mind, his memory of school, when he goes into the world, will be as vivid and exhilarating as that of a world-series baseball game. With such training, he will go through life reading, thinking, studying, growing; and every day becoming a better citizen and a better American.

3. The third study to which we would call attention is that of retarded marriage. The conditions of our industrial life delay and prevent marriage. It is practically an economic impossibility for women in industry to marry, unless they continue in industry and combine their income with that of the husband, in support of the children and the home, as our mothers did, at home. This disastrous condition manifests itself most destructively upon the best of our people, the old, sturdy American stock, who in three generations have dropped from eight or ten children to two or three children, and to one or no children in the present generation. We are sacrificing womanhood and motherhood to industry, at such a pace that in two generations, there will not be enough Yankee stock to carry on the engineering industries we have created. Notwithstanding this fact, we are gripped by the agricultural tradition that the obvious end and purpose of woman's life is marriage and motherhood, and we fool ourselves into the absurdity that our young women are only temporarily in industry, and that they will marry, after a few years in office or factory. Meanwhile the foundation upon which our industries exist, superior manhood and womanhood, dies for the want of planting. We are swiftly making our race extinct, as we did the American pigeon and the bison.

It is upon such subjects as these that we engineers must educate the brain workers, and with them build profound, scientifically correct public opinion, which shall result in cooperation between our industries and the universities and technical schools in practical organizations, to carry on social experimentation to correct the great evils, which begin to overwhelm us. Industrial plants are as worthless as a mountain of gold on Robinson Crusoe's island, unless there be intellectual people to use the products of industry. Through our lack of foresight, we are steadily destroying our race and rendering our property as useless as an iron mine in the mountain of the moon. Shall we continue to do so?

The question is, are we to be the leaders or the victims of progress?

THE EFFICIENCY OF INSULATION USED IN COLD STORAGE WORK

During the last few years there has been a great demand for information concerning the relative values of various materials that are used for insulation and this has led to extensive experimental investigations in different laboratories. While a great many factors, such as resistance to moisture, inflammability, strength, durability, etc., must be considered in choosing an insulating material, the material must of necessity be a good insulator and the measurement of its thermal conductivity is, therefore, the matter of most importance. The Bureau has developed and used for several years a very satisfactory apparatus for measuring thermal conductivity. The results obtained have been assembled and a standardized form of the apparatus suitable for general use has been designed. The American Society of Refrigerating Engineers has taken an active interest in this work, so that a standard apparatus may be available, the use of which will eliminate disputes due to differences resulting from the employment of unsuitable testing methods.

It may be said that the technical difficulties which led to such discrepancies have been largely overcome but a considerable amount of educational work is still necessary among the manufacturers and users of insulating materials in order to eliminate misunderstandings. The results of the Bureau's work will be published in a forthcoming number of the JOURNAL of the American Society of Refrigerating Engineers and will also be issued as a Bureau of Standards Scientific paper.

A report from Geological Survey states that the latest figures on the world's oil supply given out by Survey show that foreign countries are using only half as much petroleum as United States, but have seven times as much oil in the ground. These countries are now using about 200,000,000 barrels of oil yearly, but they have resources large enough to last over 250 years at this rate of consumption. In striking contrast are production figures for the United States which at the present rate of more than 400,000,000 barrels a year has only an 18 years' supply.

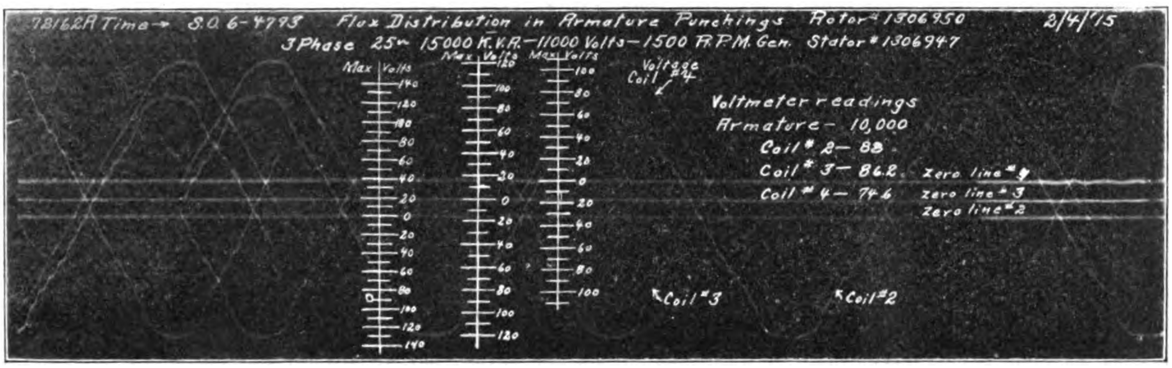
Flux Distribution in the Core of a Turbo Alternator

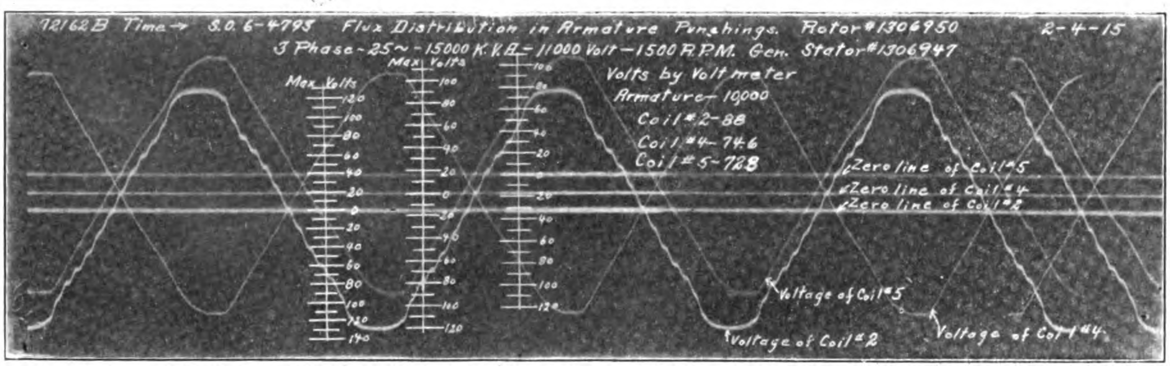
BY CARL J. FECHHEIMER
Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

ENGINEERS have long known that the density of the flux in the cores of electrical machinery changes with the depth, but there has been considerable divergence of opinion in regard to the magnitude of such variations.

In a two-pole revolving field turbo alternator, a greater variation in density would be expected than in any other type of machine. A mathematical analysis is extremely difficult, and therefore an analysis was obtained experimentally.

The alternator on which the test was made is axially ventilated; thus, there are axial holes at different radii in the stator core. Single insulated conductors were inserted in one of each of the various holes. A voltmeter and an oscillograph were connected to the terminals of each of these conductors in turn, and by means of this arrangement the voltages, as well as the wave forms of the voltage, at various depths of core, were determined. The normal voltage of the generator is 11,000, but oscillograms were taken with the terminal voltages of 8500, 10,000 and 12,500, all at no load. The oscillograms are shown as Nos. 72162–A to 72162–L inclusive. The voltmeter readings are also recorded. A picture of the stator core is shown from Fig. 4. The coil numbers recorded on the oscillograms refer to conductors placed in axial holes shown in Fig. 4; number 1 refers to the hole in the tooth, number 2, to the first hole just back of the tooth, etc.





In order to determine the space distribution of flux in the core, the oscillograms at 8500 and 12,500 volts were integrated, and the results are plotted in Figs. 1 and 2. It was found that the fluxes determined from oscillograms were in agreement with those determined from voltmeter readings, allowing for slight inaccuracies in calibration in the case of the oscillograms, and for form factors as determined from oscillograms and applied to voltmeter readings.[1]

In reviewing the various oscillograms, it is of interest to note that their shapes are not the same, and the maximum points of some of the voltage waves do not come midway between their respective zero points. Thus, whereas the shapes of the waves taken on coil No. 2 at all three voltages show that there are substantially symmetrical about ninety degree lines measured from the zero points, and that their shapes are substantially the same as those of flux density distribution in the air gap, the waves taken on coils 7 and 8 are not symmetrical about ninety degree lines, nor are the voltages of these waves at maximum values at ninety degrees. On the other hand these waves all pass through zero at substantially the same instant of time. (See *e.g.* oscillograms Nos. 72162 C, 72162 G and 72162 K coils Nos. 1 and 7). Thus, the fluxes

1. The method of integration adopted was the trapezoidal method, a description of which may be found in article by Bedell and Bown in *Electric Journal* for Jan. 1915.

must reach their maximum values along the same radial lines in the machine at all depths of core (for all three voltages), but are not zero along the same radial lines for all depths of the stator core. Furthermore, the distortion is less marked at 12,500 volts than 8500 volts for those coils toward the back of the core. Compare coil No. 8 on 72162-H for 8500 volts with No. 8 on 72162-K for 12,500 volts). Figs. 1 and 2 will give a clear picture of flux distribution radially and circumferentially. Note the points where the fluxes are maximum and where the fluxes are zero, and also compare the slight dissymmetry of No. 7 on Fig. 1 with the symmetry of No. 7 on Fig. 2. This distortion and time lag of flux are without doubt due to hysteresis and eddy currents; the former produces a direct time lag of flux and the latter sets up counter magnetomotive forces, thus delaying the time that the flux passes through zero. The less degree of distortion at the higher voltage is no doubt due to the effect of saturation with the high core densities then obtaining.

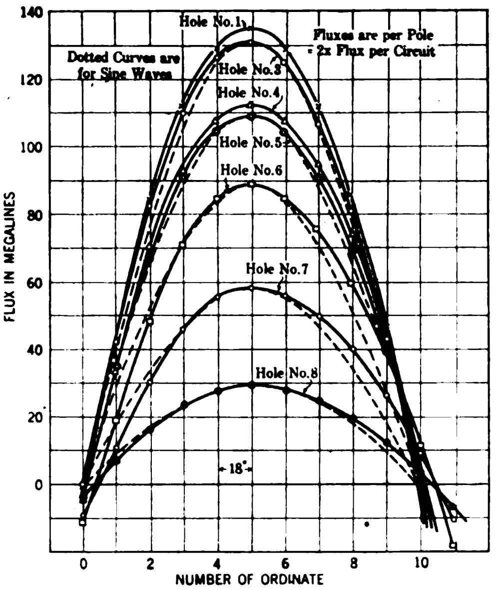

FIG. 1—FLUX BACK OF VARIOUS HOLES—8,500 VOLTS

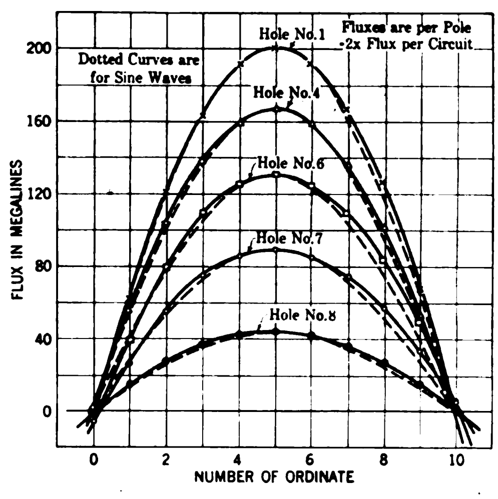

FIG 2—FLUX BACK OF VARIOUS HOLES AT 12,500 VOLTS

From the data obtained, it has been possible to draw the approximate curves in Fig. 3, these being based upon the maximum values of fluxes from curves in Figs. 1 and 2 and sections between adjacent sides of consecutive holes. If we call R_2 the outer radius, r any radius, B_0 the density at radius R_2, (K being a constant) then these curves may be quite closely approximated by equation:

$$B = B_0 + K (R_2 - r)^{3/2}$$

If R_1 is the inner radius, the average density is:

$$B_{av} = \frac{1}{(R_2 - R_1)} \int_{R_1}^{R_2} [B_0 + K (R_2 - r)^{3/2}] d r$$

$$= B_0 + \frac{2}{5} K (R_2 - R_1)^{3/2}$$

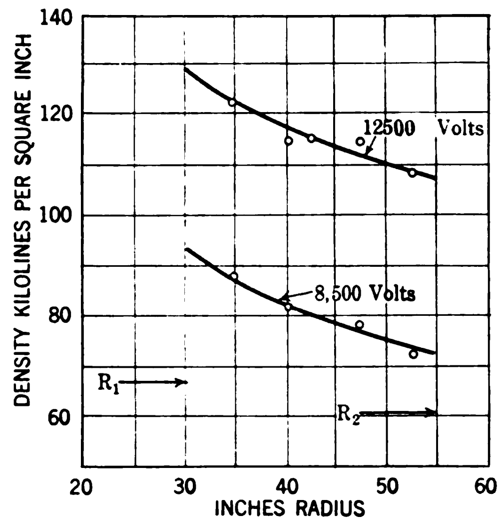

FIG. 3—FLUX DENSITY IN CORE

Thus we find the average densities for the two curves, which agree within about one per cent with the average densities figured from the total fluxes and total section; that is, within error of plotting, etc. Thus we find the following for the two curves in Fig. 3:

Volts	8500	12,500
$\frac{\text{Dens. at } R}{\text{av. dens.}}$	0.900	0.93
$\frac{\text{Dens. at } R_1}{\text{Av. dens.}}$	1.15	1.110
$\frac{\text{Dens. at } R_1}{\text{Dens. at } R_2}$	1.270	1.195

Fig. 3, we believe, to be valuable in that it shows the comparatively small change in density with depth, even with negligible saturation as at 8500 volts. Much of the flux reaches the back of the core even though

the length of its path is considerably longer than at the inner radius.

On Figs. 1 and 2 a number of sine waves have been plotted in dotted lines to indicate the degree of departure of the flux waves in space from the ideal sine distribution. We have previously referred to the dis-

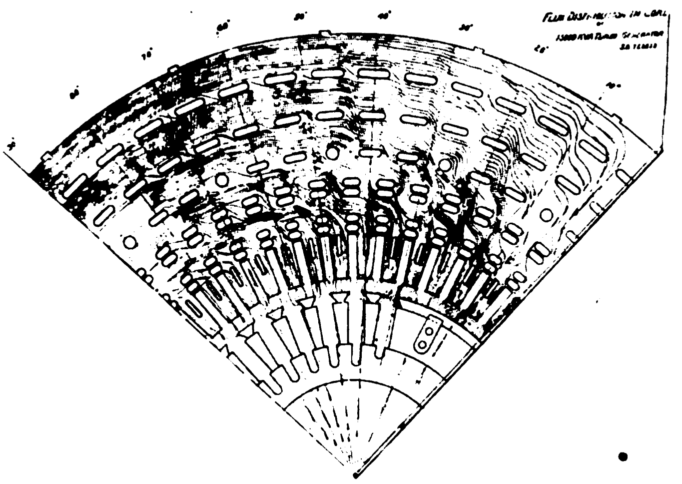

Fig. 4

tortion, and it will be seen that if in Fig. 1 the waves for holes 6, 7, and 8 be turned slightly about their point of maximum density, their departure from sine space distribution will not be very great. The other waves in Fig. 1 and 2 agree sufficiently with the sign curves to enable sine wave distribution to be assumed

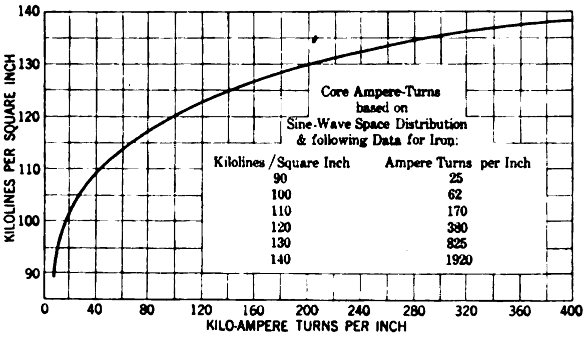

Fig. 5

for calculations. Especially at the higher voltages will this be true (Fig. 2), and we therefore assumed sine wave space distribution in calculating densities which enabled the drawing of flux distribution, shown in Fig. 4. Thus Fig. 4 does not show one distortion which is especially pronounced when the flux passes through zero at the lower voltages but is nearly negligible at 12,500 volts for which Fig. 4 is drawn. Even with sine wave space distribution Fig. 4 is only approximately correct, and its purpose is solely to give a slightly clearer picture of the distribution in the core.

We may employ the assumed sine wave distributon for estimating the ampere turns required to drive the flux through the stator core, which may be of assistance in predicting saturation curves. We take the ampere turns needed for the mean length of path for the mean density to be the same for any depth. The curve which we have calculated is shown in Fig. 5. To illustrate the method, calculations at average density of 130,000 lines per square inch are given below:

				B	A. I. inch
First........	5 deg.	130 cos 2 ½ deg.	=	130	825
Second......	5 deg.	130 cos 7 ½ deg.	=	129	755
Third.......	5 deg.	130 cos 12 ½ deg.	=	126.9	640
Fourth......	5 deg.	130 cos 17 ½ deg.	=	124	500
Fifth........	5 deg.	130 cos 22 ½ deg.	=	120.2	380
Sixth.......	5 deg.	130 cos 27 ½ deg.	=	115.3	265
Seventh.....	5 deg.	130 cos 32 ½ deg.	=	109.7	160
Eighth......	5 deg.	130 cos 37 ½ deg.	=	103.1	85
Ninth.......	5 deg.	130 cos 42 ½ deg.	=	95.8	42
Tenth.......	5 deg.	130 cos 47 ½ deg.	=	87.8	22
Eleventh....	5 deg.	130 cos 52 ½ deg.	=	79.1	15
				Total amp. turns =	3689

The ampere turns beyond the eleventh 5 deg. are neglected, but we may consider the 3689 ampere turns as having covered 90 electrical degrees. As we have considered five electrical degrees to correspond to one inch of length, 90 degrees correspond to 90/5 = 18 inches. The ampere turns per inch will be 3689/18 = 205. In using Fig. 5, figure the average core density in ordinary way, and then use as length

$$\frac{\text{(External diameter} = \text{depth of core).}}{\text{Number of poles}}$$

Result will be in ampere turns per pair of poles.

It is well-known that, per pound of material, the core losses, in radially slotted rotor type of turbo alternator, are usually materially less than in salient pole alternators, although higher than in transformers. Undoubtedly, the lowered rate of change of flux density due to the approximate sine wave space distribution of flux as compared with the more abrupt rate of change in the salient pole machine, is to a large extent responsible for this reduction. Another cause may be attributed to the lower percentage of iron loss in the stator teeth of the turbo owing to the great depth of cores in that type compared with the general proportions to be found in salient pole alternators.

Portable Oscillograph

BY J. W. LEGG

Westinghouse Electric & Mfg. Co.

Introduction

THE use of the oscillograph for recording the instantaneous values of electrical phenomena has steadily increased in both scholastic and commercial institutions. Formerly it was seldom necessary to use the oscillograph in the field. However, due to the increasing complexity in transmission circuits and in railway electrification problem, it has become more and more desirable to have a special, portable, commercial oscillograph which, besides having the properties of the best laboratory oscillograph shall also be extremely compact and light in weight.

This article describes such an oscillograph which, furthermore, is permanently assembled in two units, which have been taken by the engineer into a Pullman to the place of test, and set up, ready for use in half an hour's time. There are many novel features in this oscillograph which make it independent of a direct-current supply, and which makes it adjustments more permanent, its operation more simple, and its results more reliable than heretofore possible with other forms of oscillographs.

The Oscillograph and its Galvanometer

An oscillograph consists essentially of an optical system for throwing a beam of light onto the vibrating mirror of the galvanometer which mirror in turn reflects this beam of light onto a photographic film, passing at right angles to the vibrating beam, some distance from the galvanometer. This makes a *current-time* record, on the film; in which *distance* along the film is proportional to *time*, and *deflection* (of the beam of light) is proportional to the *instantaneous* value of *current* passing through the galvanometer vibrator.

Several standard makes of the moving coil oscillograph galvanometer were considered when the writer first planned a more portable commercial oscillograph. The permanent magnet type was light in weight but did not have a short enough natural period of oscillation to act properly on very fast transients or to respond to the high harmonics in some alternating current waves. The best standard electromagnet types of oscillograph galvanometer were superior in characteristics of natural period and sensitivity but were bulky and required a supply of direct current (usually 110 volts). Both of these drawbacks were serious for a portable commercial oscillograph, and hence an entirely new galvanometer and accompanying apparatus were designed to fulfill the more exacting requirements.

Surmounting Former Difficulties

This oscillograph was designed to be independent of direct-current supply, for it is often desirable to make oscillograph records in a power-house, substation, factory, etc., where there is either no direct-current supply or where the supply is unreliable, due to sudden voltage changes. Former oscillograph apparatus which used d-c. for the galvanometer fields, arc lamp, electrically operated shutter, etc., required a two-kw. motor-generator set, or a large storage battery (which had to be kept charged) when no suitable d-c. supply was already available. Such was usually larger and much heavier than all of the other oscillograph apparatus combined.

As alternating current is in much more general use, for lighting and for power, the light source and the film motor were designed to operate on a-c. An incandescent lamp was used (with special means to give the filament great intrinsic brilliancy), the photographic shutter was designed to operate mechanically, and the galvanometer field circuit to operate on ten watts, supplied by a small storage battery, all being enclosed in the oscillograph case. This case also contains the low and high resistances, for each of the three galvanometer elements, in order that they may be used for any potential up to several thousand volts.

The lamp and the film motor are operated from a small transformer which may be plugged into any ordinary lamp socket or power supply of approximately *110 or 220 volts at any frequency from 20 to 70 cycles*. Thus this portable apparatus requires, momentarily, less than 300 watts, a-c., instead of 2000 watts, d-c. (as was formerly required).

If a test is to be made where there is no alternating current supply, the gas filled incandescent lamp may be readily removed and an external d-c. arc lamp substituted. Also a d-c. motor can be used in place of the induction motor, for driving the photographic film. In practise it has been found that alternating current is almost always available, while proper direct current is seldom available outside of the laboratory.

A general view of the portable oscillograph is shown in Fig. 1. The main oscillograph case is shown to the left. This is 14 inches high, 13 inches wide, and 25 inches long over all. It contains the lamp house. shown at extreme left, the galvanometer, in the rear upper part of the case, the optical box, to which the photographic drum is attached, the ammeter and control switches, the element resistances with their control panel and the storage battery.

To the right is shown the motor board, on which are mounted: the induction motor with helical gears. for driving the photographic drum at desired speed. the transformer, and the control panel, with switches, fuses and lamp rheostat.

These two units together weigh but 135 pounds including side covers and carrying arrangement. They

take the place of former apparatus which weighed (ready for shipment) *from one-half to two tons* (depending whether or not suitable 110-volt direct current was available at the place of test).

The *galvanometer* is shown in Fig. 2. This instrument is 7 inches square, at the base, and 4¼ inches high over all. There are three separate elements, each insulated for over 10,000 volts from its neighbor. The most novel feature is the electromagnetic series field circuit. There is but a *single* exciting coil which forces the magnetic flux in a *series path* through the three elements. There are three effective gaps in the iron circuit, one for each element, and four *insulating gaps*. The effective gaps are small in cross-section so as to concentrate the magnetic flux about each vibrating element. The insulating gaps are of micarta and are large in cross-section so as to have the least possible reluctance and still present sufficient insulation between the elements. This design is so efficient that it requires but 10 watts, applied to the field coil to nearly saturate the element pole tips, thus giving as strong a magnetic field as is practical.

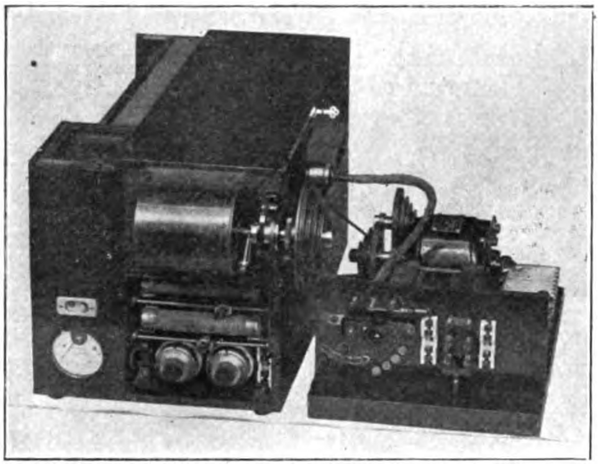

Fig. 1—Portable Oscillograph in Two Units

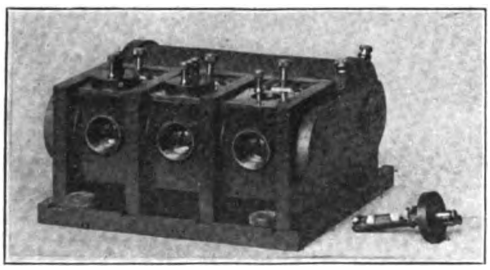

Fig. 2—Three-Element Galvanometer Series Magnetic Circuit

One *vibrator element* is shown to one side, the other two elements are in place in their wells. These wells contain the damping fluid which prevents over-travel of the vibrating mirrors. They are closed by the element tops so as to be both dust and oil tight. This feature is quite important for a portable oscillograph. The very fine ribbon of metal, which forms the moving coil of the galvanometer, is entirely immersed in oil. A low resistance of the same material, is mounted in air so that it will clear the circuit, when an excessive current passes, and thus save the element.

As is the case with most *moving coil oscillograph galvanometers*, the coil actually consists of a single turn of very fine conductor, supported by two ivory bridges so that the effective part of the coil is essentially two parallel wires with the current passing down one wire and up the other. The motoring action of the conductors, carrying a current at right angles to the lines of force of the magnetic field, tends to force one wire forward and the other backward, in proportion to the current passing through them. These parallel conductors are kept taut by a tension spring which transmits its force to the loop through a lever and a tiny ivory pulley. The lever is *balanced* so that any shock will not tend to break the fine conductor. A very small mirror bridges the parallel conductors at the center of the magnetic gap. This reflects the beam of light to the photographic film. With this optical advantage the deflection is approximately one inch to 0.12 ampere. Any element may be used across a shunt, as a millivoltmeter, to record instantaneous current, or, with a series resistance, to record instantaneous values of voltage.

Fig. 3—Panel Side of Oscillograph Case

Fig. 3 shows the front and the element resistance *panel side of the ocillograph.* There are three similar sets of switches and binding posts, one set for each element. Each set consists of two dial resistances, one with a range from 0 to 100 ohms and the other from 100 to 10,000 ohms. The double-pole, double-throw knife switch places the element, and its fine fuse, in series with either the high-resistance or the low-resistance dial. There are four binding posts per element. The two closer together are in the low resistance circuit, for use with e.m.fs. below 10 volts, or for connection across a current shunt. The other two posts have a greater spacing to indicate that they are to be used for higher voltages, with the higher resistance. With this connection the element can be used to record the instantaneous values of e.m.f. up to about *4000 volts*, d-c., or about 1500 volts, a-c. In every case the resistance is nearest the left hand

terminal so that when high voltage is used the right hand terminal can be kept in the side of the line nearest the ground, thus keeping the element on the ground side. If more than 10,000 ohms is desired, in one element circuit, one of the other high resistances can be connected into circuit.

This whole panel, with all the resistance units, can be removed from the oscillograph for inspection or or repair. The resistances are wound on thin micarta cards, so as to be as non-inductive as possible. They are located behind the panel, underneath the galvanometer compartment.

The adjusting screw for the incandescent lamp is shown below the smoked glass window and above the battery charging terminals.

A fine wire screen between the element resistance panel and the galvanometer partition, allows ventilation of the element resistances.

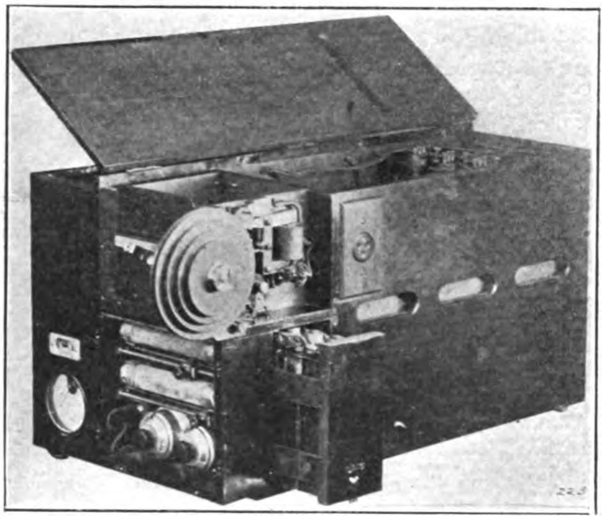

FIG. 4—BATTERY COMPARTMENT SIDE OF OSCILLOGRAPH

One of the *snap switches,* in front, connects the ammeter to indicate either the galvanometer field current or the battery charging current. The normal field current is 2¼ amperes. The conveniently located switch, above the ammeter, is in the field circuit and is used to conserve the battery current when no charging current is at hand. The variable resistances are in the battery and galvanometer field circuits.

Fig. 4 shows the *battery compartment side of the oscillograph.* The common cover to the galvanometer compartment and optical box is shown in its raised position. The top of the galvanometer can be seen at the rear. Below this is the element resistance compartment with 30,000 ohms of non-inductive resistances. The three longitudinal ventilating slots can be seen at the side. There are nine similar slots in the base, to allow cool air to enter below the resistances.

The *storage battery* is shown half withdrawn from its compartment. Above is shown the rectangular plate with the three-point plug receptacle, used in connecting the incandescent lamp and trip magnet mechanism to the low-voltage side of the transformer. The trip magnet is shown on the side of the optical box, in a recess near the film pulley.

Fig. 5 is a detailed view of the trip magnet, remote-control switch, photographic shutter release, lamp-extinguishing switch etc. These are all novel features and all add greatly to the efficiency and simplicity of operation of the oscillograph.

As mentioned before, *the shutter is mechanically operated* and is of the semi focal-plane type. This is

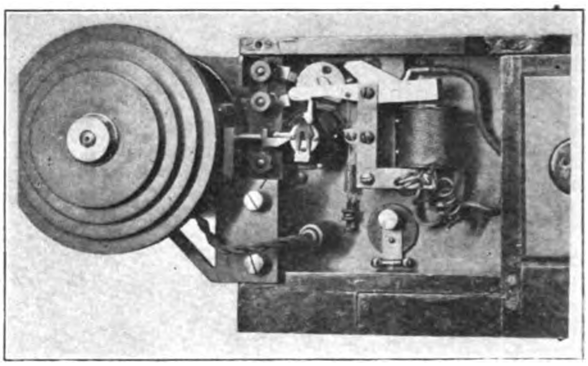

FIG. 5—SHUTTER TRIP AND REMOTE CONTROL MECHANISMS

so arranged as to permit the reflected beams from the tiny vibrating mirrors to strike the film for just one complete revolution. Also the start of the exposure always comes very near the beginning of the rectangular film. *With this arrangement no important transient could ever occur just at the overlapping of the film.*

The *shutter* is essentially a hollow cylinder with a longitudinal slot on each side. When these slots line up, horizontally, the shutter is open. The cylindrical condensing lens lies just between the shutter and the film holder.

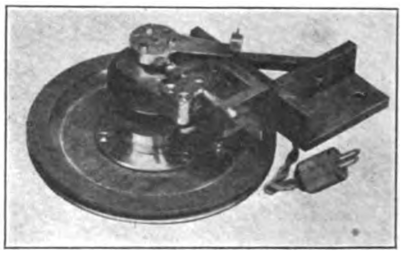

FIG. 6—DRIVING HEAD

The *shutter operating device* is in two main parts. The radial fingers and hub, on the shutter shaft, receive a torsional force from the spiral spring. The release arm is actuated, through a connecting rod, by a crank pin on the film pully shaft. When all is ready for the phenomena to be recorded on the photographic film, the trip magnet releases the longer of the two radial fingers; this allows the shorter finger to rest on the release arm. When the arm almost reaches its extreme travel, away from the shutter, the short arm drops, due to the torsional force exerted by the

spiral spring, the longer finger is stopped by the arm, thus holding the shutter open. As the arm returns it forces the longer finger into the hub, and as it moves outward again a flat spring holds this finger in, so that it is now just the same length as the first finger. When the arm reaches its outward position again the second finger drops and the shutter closes, after allowing just one revolution exposure on the revolving film.

The instant the *trip magnet* is excited it releases the remote control switch, but the shutter does not open until the overlapped end of the film is presented towards the galvanometer. A contact on the film pulley shaft,

Fig. 7—Optical Box

may be set so as to trip the magnet at any interval of time, ahead of the exposure, equal to the time lag of the remote controlled apparatus (circuit breaker, switch, relay, fuses, etc.) being studied. Thus, if the operator desires, he can cause the transient phenomena to occur within 0.01 sec. after the beginning of the exposure. This is of *great value for commercial work,* where many fast transient conditions must be recorded.

Fig. 7 shows the *optical box* on its face with the under side nearest the observer. This is made of aluminum so as to be as light in weight as possible. The trip magnet, shutter fingers, observation door, etc., can be seen to the left. The condensing lens is adjustable and can be twisted to one side when an external arc lamp is to be used. There are four reflecting prisms and slots, one set for each element, and one for a stationary beam or for a timing line device. All of these are very conveniently adjusted from above, their knurled heads being in plain view when the main cover is raised. Furthermore, when using the incandescent lamp, these various items need to be adjusted but once, and then *any number of oscillograms may be taken without further adjustment,* until renewal of the lamp.

Fig. 8 shows a close up view of the *motor board.* The rheostat switch on the panel, is in the lamp circuit, which is supplied from the low-voltage secondary of the transformer. The first contact closes the lamp circuit through sufficient resistance to give normal voltage to the lamp. This *lamp* is of the low-voltage, high-current type with an extremely concentrated filament. The central part of this filament is arranged to have maximum intrinsic brilliancy, its normal brightness being increased by the light from the surrounding coil of the filament. Intrinsic brilliancy, and not total candle power, is of prime importance, for only a projected area of about 20 miles square can be used to any advantage.

The second contact position, on the *lamp control switch,* increases the voltage, applied to the lamp, by about 12 per cent, the third by 30 per cent, and the fourth by 60 per cent. The lamp would burn continuously, many hours, on 112 per cent voltage, but would have a short life at 130 per cent volts. At 160 per cent voltage, filament life would be less than one second. For this reason an automatic *lamp extinguishing switch* is used. This is located between the trip magnet core and the optical box. The closing of the shutter snaps open this special switch. The lamp cannot be lighted except when the shutter is set. A special combination stop and contact is provided, under the lamp control switch arm, so that the instant the desired abnormal voltage is applied, to the lamp, the trip magnet operates the remote-control switch, the shutter opens, the oscillograph record is made, the shutter closes, and in so doing opens the lamp extinguishing switch, thus saving the lamp. With this arrangement hundreds, and possibly thousands of films may be taken before the lamp burns out. The value of the abnormal voltage chosen depends on the speed of the film, for high-speed films require much greater intrinsic brilliancy than low-speed films.

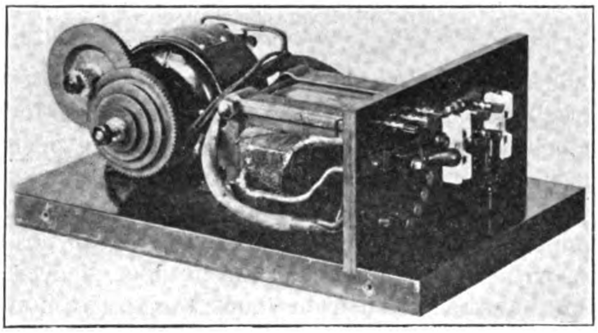

Fig. 8—Motor Board, With Transformer and Control Switches

Note that the lamp is thus at the greatest abnormal voltage for the shortest period of time, and at a moderate voltage for a longer period of time. The abnormal voltage increases the intrinsic brilliancy *many times,* thus enabling one to take oscillograms, with this incandescent lamp, which otherwise would require a direct current arc lamp consuming ten to twenty times as many watts. For some very special work, where the film speed must be greater than about 100 inches per second, it becomes necessary to use a direct-current arc. This can be applied to this oscillograph

in a few moments time, when direct current is available. If great accuracy is required in *recurrent phenomena* (such as in determining wave forms) it would be much better to *use the synchronous polar film*[1] with the incandescent lamp, than to try to get a large scale wave on the rectangular film.

The double-pole double-throw transformer switch places the two primary coils in series or in parallel; the former for 220-volt, and the latter for 110-volt supply. The single-pole switch throws the induction motor on 110 or 55 volts, for 60 or for 25-cycle supply. Actually the motor will run on any frequency from 20 to 70 cycles.

The four steps in the *pulleys*, together with the *helical gears*, give an ideal range of speed reductions. When the motor pulley is pushed in, a clutch engages with the motor shaft and gives direct drive. When this pulley is pulled out it is driven, through the back gearing, at one sixteenth motor speed. The four steps, for the round belt, are so arranged that the center distances are the same, for the four belt positions.

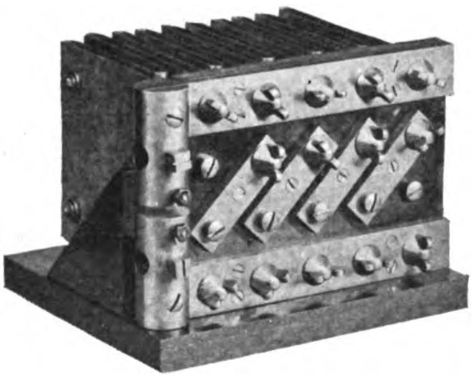

FIG. 9—VARIABLE SHUNT

Provided the induction motor supply does not vary in frequency the film speed remains the same for any one belt position, within a fraction of one per cent. This is a great advantage, for *no timing wave is needed*, on any film, after the film speed has once been determined, for that particular belt and gear position. Also, with this arrangement the number of cycles on a film, may be varied from about two to two hundred and forty. This is a greater range than is needed for any but a commercial oscillograph.

Fig. 9 shows the variable, non-inductive shunt which was designed to go with the portable commercial oscillograph. It consists of five manganin strips with special arrangement for connecting any number of them in series or in parallel. Furthermore their arrangement makes them very nearly non-inductive. When the five strips are all in series the resistance drop is great enough to give a good deflection, on the above oscillograph, with a shunt current of 10 or 20 amperes. With the strips all in parallel, approximately the same deflection would be produced by 500 amperes as was produced by 20 amperes in the series position. The shunt will carry about one thousand amperes continuously and can be used for momentary currents of 50,000 amperes.

The heavy terminals, to the left, receive the power conductors. The arrangement for connecting the strips either in series or in parallel is very convenient. Two heavy brass screws are connected to each end of each of the five strips. One from the right hand side of each strip passes through one bus bar, but is insulated therefrom; and one from the left hand side of each strip passes through the other bus bar, likewise. As the wing nuts are turned down, on these screws of any one strip, that strip is placed across the bus bars. A set of four diagonal conductors, screws and wing nuts make it possible to connect any number of the strips in series. One series-parallel arrangement is also possible. If the drop across the shunt makes too great a deflection, when the element is connected straight across it, series resistance is added in the element circuit by means of the upper dial switch shown in Fig. 3. The resistance of the strips was so chosen that 50 amperes direct current through one strip, gives a deflection of once inch, with no series resistance added to the element circuit. With five ohms, series resistance, added to the element circuit it takes 300 amperes to give one inch deflection. In general the following formula holds, approximately.

Where A = current in amperes D = deflection on film in inches.

P = number of strips in parallel S = number in series.

R = external resistance in element circuit, in ohms.

50 = amperes in one strip to give one inch deflection on film with no external resistance in element circuit.

Then $A = 50D\ (1 + R)\ P/S$ or, sensitivity = amperes per inch = $50\ (1 + R)\ P/S$.

Except for approximate work any oscillograph should be calibrated by passing a steady value of direct current through the particular shunt being used with the same resistance in series with the element as was used in the important test. If this requires a very large current (to give the proper deflection) the true calibration could be figured from the results of a calibration obtained with a much lower current passing through a much higher resistance shunt; the currents required to give the same deflection being inversely proportional to the shunt resistances. Thus, 200 amperes passing through the five strips in series would give approximately the same deflection, on the film, as 5000 amperes flowing through the five strips in parallel. When the exact ratio of resistances is known this can be figured quite accurately.

This one shunt is suitable for a *very great range* of

1. L. W. Chubb, *Electrical Journal*, May 1914.

work, and yet can be carried in a space 10 by 10 by 8 in. Naturally, however, it cannot be extremely light in weight and still be suitable for even a momentary current of 50,000 amperes.

For heavy alternating currents it is advisable to use current transformers with five ampere shunts in the secondary circuit, as is the general practise.

The shutter mechanism construction makes it possible to use a special film holder having a long film, in a magazine, on which several exposures can be taken without reloading, and without the help of a dark room. It would be impossible to use such a film for transients unless the oscillograph shutter mechanism caused the exposure to begin at the same part of the revolving drum, each time, as is the case with this instrument.

The operator can make all oscillograph adjustments and all connections with the apparatus to be tested, at his leisure; then when all is ready he has but to *depress the control switch and everything works automatically.* In fact, the operator could be miles away from the oscillograph, and by the pressure of a single button the whole apparatus could be made to function perfectly.

This oscillograph has been used to operate, successively, a closing switch, which caused an abnormal current to build up through an inductance, then to trip a circuit breaker and operate the polar, multi-exposure, high-speed camera[2] so that the latter would make a series of photographs of the rapidly extinguished arc, while the oscillograph made a complete record of the building up and rupture of the current, and the accompanying voltage surges.

2 J. W. Legg, *Electric Journal*, December, 1919

Summary of the Special Features of the Portable Commercial Oscillograph

1. Special compactness of apparatus, including the series electromagnet galvanometer.
2. Use of an incandescent lamp with special arrangements to obtain very great intrinsic brilliancy.
3. Mechanically operated focal plane shutter, which always starts exposures at the beginning of the film.
4. Remote-control switch to cause transient to appear at any desired part of the film.
5. Trip magnet to operate remote-control switch and shutter immediately after abnormal voltage is applied to the incandescent lamp.
6. Lamp extinguishing switch to prevent the filament from being destroyed.
7. Self-contained storage battery to supply galvanometer field.
8. Switch for placing ammeter in galvanometer field or battery charging circuits.
9. Element resistances and control panel for commercial voltages.
10. All the above apparatus mounted in a single case 13 by 14 by 25 inches over all, and weighing but 82 pounds.
11. Transformer, for 110 or 220 volts, 20 to 70 cycles, supply for incandescent lamp, trip magnet, and induction motor operation.
12. Switches for motor, transformer and lamp control.
13. Induction motor with back gear and step pulley arrangement for driving photographic drum at uniform speed over a great range of speeds.
14. This *portable commercial oscillograph* arranged in but two units which together weigh but 135 pounds, including storage battery and transformer.

THE ELECTRIFICATION OF STEAM RAILROADS

One of the most important subjects to come before the recent N. E. L. A. Convention was "The Electrification of Steam Railroads," and the report of the Committee was submitted at the third general session, Friday, May 21, by Mr. Frank M. Kerr, of the Montana Power Company, of Butte, Montana, who is Chairman of the Committee. An abstract of Mr. Kerr's elaborate study on the subject is as follows:

"If all the steam railroads in the country were electrified with power furnished from large steam-generating electric stations, the total fuel required would be equivalent to 53,500,000 tons of coal, as against the actual figure for railroad coal used during the year 1918, of 175,000,000 tons. Thus, by electrification of the railroads, 122,500,000 tons of coal would have been saved.

"The Chicago, Milwaukee & St. Paul Railway and the Montana Power Company have demonstrated in Montana the entire practicability and great superiority of electric power for the operation of a heavy trunk-line railway, by more than four years of 100 per cent operation. Four-thousand-ton trains go up and down heavy mountain grades under perfect control, at speeds never known before and with a regularity which is phenomenal."

"The change from steam to electric operation means more than a mere change in type of locomotive used. It means a change in the entire conception of the art of railroad transportation."

"In short, by adopting electrification, the railroad company is relieved entirely of the business of generating power, and is enabled to concentrate on its main business of transportation." * * *

"The higher speed at which cars can be hauled over a road with electric operation allows the same amount of freight to be handled with a considerably smaller number of cars. This is such an important item that it is safe to say that if all the roads in the country were electrically operated at the present time there would be no car shortage."—*N. E. L. A. Bulletin.*

A Dynamometrical Comparator

A Differential Dynamometer for Accurate Comparison of Alternating and Direct-Current Strengths

BY EDY VELANDER

Electrical Engineering Research Division; Massachusetts Institute of Technology

ACCURATE ALTERNATING-CURRENT MEASUREMENTS.

IN a direct-current measuring instrument, the deflection is usually proportional to the strength of the current to be measured, and it is also proportional to the strength of a magnetic field, produced by permanent magnets. In the corresponding alternating-current instrument, the magnetic field must ordinarily be produced by the measured current itself, and the deflection will therefore be inherently quadratic with respect to the measured quantity. In a thermal instrument, the heating effect of the current is observed, and the scale is likewise quadratic. This correspondingly holds for electrostatic alternating-current instruments. With this inevitable second-power relation follows uneven scale divisions, and poor sensitivity at low values, two circumstances which have a decidedly detrimental effect upon the accuracy of alternating-current measurements. In work requiring a high degree of precision, some indirect method is therefore often employed, and the alternating-current measurement is reduced to a direct-current measurement by use of an intermediate apparatus, which may be generally called a *comparator*. By aid of the comparator some effect of the alternating current to be measured is either observed, through direct-current measurements, or neutralized by means of a direct current, the exact value of which may be determined with the extremely high accuracy of the direct-current potentiometer.

Thermal Comparators. Very often the comparator is based upon an observation of heating effects. So in the common "thermocouple," where the temperature of a heater is observed by means of a thermocouple, and millivoltmeter or potentiometer, and also in the bolometer, where the change in resistance of the heater is observed in a d-c. bridge, and taken as a measure of the strength of the alternating current. Both of these instruments must be calibrated on direct current.

In the ordinary thermocouple, mutual interactions between the a-c. circuits and the auxiliary d-c. system are avoided by using only a one-point interconnection. In an improved form of the bolometer[1] a double balance in a Wheatstone bridge is used for the same purpose. The heater is built in the form of a quadrilateral with equal sides, the direct current entering and leaving by two opposite corners, while the alternating current to be measured is supplied at the two other corners. Since the four arm-impedances are all alike, the bridge formed by the heater will be in a double balance, and there will be no a-c. potential difference between the d-c. terminals, nor any d-c. potential difference between the a-c. terminals of the bridge, and the two thus will be electrically independent. In a similar instrument, the barretter[2] condensers are used to restrict the direct current to its system, while choking coils prevent alternating current from straying into the d-c. system.

The Barbagelata Differential Current Balance. The principles of an ingenious dynamometrical comparator, where the Wheatstone bridge is used for separating alternating and direct currents, were suggested by Barbagelata in 1908[3]. In a Kelvin current balance, the two fixed and two movable coils are arranged in a bridge, as shown in Fig. 1. Connection is made to the moving part of the balance through the pivot, at *a*, and also through mercury cups, or flexible leads, at *b* and *d*. Alternating current is supplied to the system at the

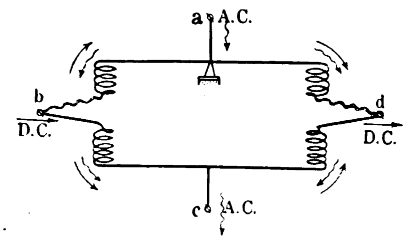

FIG. 1—THE BARBAGELATA DIFFERENTIAL CURRENT BALANCE

points *a* and *c*, while the direct current enters at *b* and leaves at *d*. If an electrical balance is maintained, one-half of the direct current will pass through the moving part, and one-half through the fixed part of the balance. Similarly the alternating current will divide evenly over the left and right hand parts of the system, but due to the bridge feature, no interactions will occur between the a-c. and d-c. systems. It will be seen, from an inspection of the figure, that if the alternating current and the direct current have the same directions in the upper coil on either side, they will flow in opposite directions in the lower coil, and vice versa. Their torques therefore will *oppose,* and at a certain value of d-c. strength the resultant torque will be zero. It is also immediately seen that this instrument is an absolute comparator in the sense that no calibration is necessary. Since alternating current and direct current flow in the same coils, equality of torque means equality of r. m. s. values, without reference to any instrument constants. (In a heavy-current

1. See reference at end of paper.

balance with few turns of large cross-section conductor, uneven current distribution may cause deviations from a one-to-one ratio.)

The New Dynamometrical Comparator. Independently of the Barbagelata differential balance, a dynamometrical comparator, working on very similar principles, has been developed at the Electrical Engineering Research Division of the Massachusetts Institute of Technology, according to a suggestion from the U. S. Bureau of Standards. The new instrument was constructed by Mr. C. O. Gibbon[4], and in its first form was described by him[5]. It is built in the form of a sensitive electrodynamometer, and contains a system of fixed field coils, and a strip-suspended oil-damped moving coil. The deflections are observed by the mirror and beam-of-light method. (For a detailed description of the apparatus see Mr. Gibbon's paper).

To make this instrument work as a comparator, the fixed and moving coils were connected as tow arms of a bridge, as indicated in Fig. 2, the other tow arms of the bridge being made up of an identical set of coils, forming a "dummy" instrument, which served only for obtaining the bridge-balance.

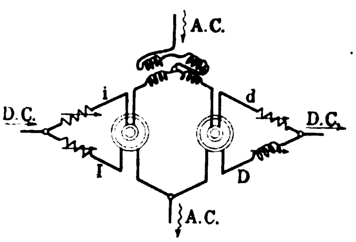

FIG. 2—THE GIBBON DIFFERENTIAL DYNAMOMETER

Mr. Gibbon gives as conditions for the double balance:

$$R_I = R_i = R_D = R_d, \quad (1)$$
$$L_I = L_D : L_i = L_d, \quad (2)$$
and $$M_{iI} = M_{dD}. \quad (3)$$

The last condition was satisfied by adjusting the fixed and moving coils at right angles to each other, making $M_{iI} = M_{dD} = 0$. The equality (1) involves three resistance-adjustments, made on three variable resistances, one in each of three arms, and the conditions (2) were obtained by means of a mutual inductance and a small variable inductance, as indicated in the figure.

The great number of necessary adjustments, and the difficulty to obtain accurate checks upon each one during the use of the instrument, made the practical application of the comparator in its earlier form somewhat cumbersome. However, from some tests made with the apparatus in this temporary bridge-arrangement it became at once clear that this differential dynamometer possessed some very remarkable properties, and in particular that it permitted the measurement of alternating currents of a few hundredths of an ampere with an accuracy far beyond that of any other available instrument.

Second Stage of Development. In connection with some research in alternating-current potentiometry the writer therefore undertook to study the instrument with a view to adapting it for accurate current measurements in the laboratory[6]. It was found that by making certain changes in the connections, a considerable simplification could be effected so that the number of adjustments, necessary to make and check during the use of the apparatus, could be reduced to one. By assembling all auxiliary parts, needed for the adjustment and manipulation during use, into one box, which could be placed within easy reach of the observer, the use of the comparator for actual measurements was still more facilitated. In the following this second step of development will be described, by which the instrument was carried from the experimental stage into the ranks of useful laboratory tools. The development work and tests here described were carried out in the laboratories of the Electrical Engineering Research Division of the Massachusetts Institute of Technology, and the writer is much indebted to the Director of this Division, Dr. A. E. Kennelly, for the encouragement and the valuable suggestions he has given in the course of the work.

Simplified Connections. It is not essential that all four arms of the comparator-bridge shall contain inductance since the d-c. distribution is not affected by its presence. By interchanging the points of supply of d-c. and a-c. in Fig. 2, the dummy can therefore be omitted, and replaced by two non-inductive magnanin resistances adjusted once for all to a certain value. The big field coils of the instrument, if wound with the same resistance as the small moving coil, will have a much bigger inductance than the latter, and as a rule will also have different cooling conditions, so that they are liable to change resistance due to Joulean heat in another proportion than does the moving coil. For similar reasons the change in apparent resistance and inductance which occurs at higher frequencies, due to skin effect and coil capacity, will as a rule be different for the small coil and for the larger one. Therefore, in order to get, in one stroke, an approximate resistance—and inductance-balance, and also symmetrical conditions, not only thermally, but with respect to high-frequency disturbances as well, the dummy was not thrown out, but was instead transferred to the instrument side of the bridge, and connected so that each of the two working arms of the bridge contains one big and one small coil, as shown in Fig. 3. The two remaining arms of the bridge are formed by the ratio-coils N_1 and N_2, which are bifilarly wound of *Ia . Ia* resistance wire. In the existing instrument, the sum of the resistances of the small and the big coil was a little less than 250 ohms, and the ratio-coils N_1 and N_2 were therefore accurately adjusted to this value.

Astatic Double-Instrument. The use of a dummy clearly represents a waste of power, and for the same sensitivity doubles the instrument resistance. In

future new-construction, the instrument therefore should be built either with two as nearly as possible identical coils, or the dummy should be incorporated as a working part of a double-instrument with two equal systems of field coils, and with two identical moving coils put on the same suspension. It is also conceivable that good results could be obtained in a double instrument with one active coil in each arm, whereby the coils N_1 and N_2 could be omitted and the total resistance thus halved. By this arrangement, however, the simplicity in manipulation would be sacrificed, which follows the introduction of constant-resistance coils in two arms.

In its present form the apparatus is strongly susceptible to stationary magnetic fields, such as the field of the earth, and direct-current stray fields, as well as to alternating magnetic fields of the same frequency

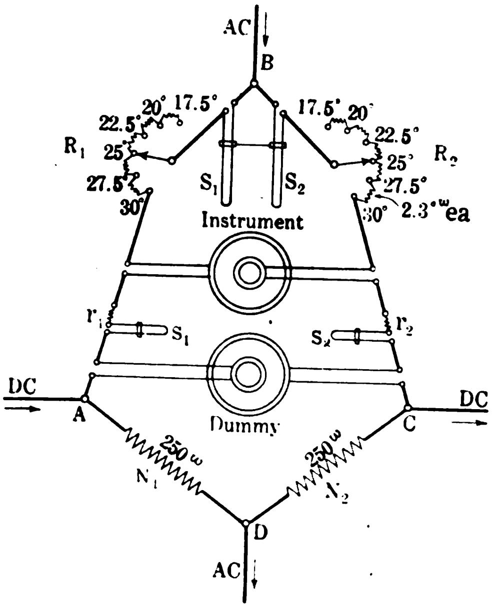

FIG. 3—THE NEW CONNECTIONS OF THE COMPARATOR

as the measured current. The field coils also send out powerful stray fields which may cause disturbances in other apparatus. By proper connection of the coils in a double instrument of suggested form, the conditions of a complete astaticism could be approached, which would tend to eliminate the mentioned inconveniences.

Adjustments. Considering Fig. 3, we find that the following relation must hold in order that the direct current shall split into two equal parts:

$$R_1 + R_2 = N_1 + N_2 \qquad (4)$$

Corresponding condition for the splitting of the alternating currents into two parts, equal in amplitude and phase, is in complex notation

$$R_1 + N_1 + j\,\omega\,L_1 = R_2 + N_2 + j\,\omega\,L_2 \qquad (5)$$

or, since $N_1 = N_2$,

and
$$\begin{cases} R_1 = R_2 & (6) \\ L_1 = L_2 & (7) \end{cases}$$

Mutual inductance between arms 1 and 2 will in this case evidently not affect the current distribution.

Now, if

$$R_1 : R_2 = N_1 : N_2 \qquad (8)$$

or again

$$R_1 = R_2 \qquad (6)$$

then there will be zero d-c. potential difference between the points B and D. This, however, is not essential, since the direct current may easily be cut off from the a-c. system by means of blocking-condensers at these terminals.

In order that no alternating current shall enter the d-c. system, we should have

$$(R_1 + j\,\omega\,L_1) : N_1 = (R_2 + j\,\omega\,L_2) : N_2 \qquad (9)$$

Since $N_1 = N_2$, this equation reduces to conditions (6) and (7).

The condition (7), or $L_1 = L_2$, may be easily adjusted once for all by changing the inductance of either arm.

However, since the two instrument arms of the bridge contain copper resistances, it is necessary to have some temperature compensation, such as is provided by the dial rheostats shown in Fig. 3. Each dial-step corresponds to a 1 per cent resistance increase, or a 2.5 deg. cent. rise in average temperature of the system. The slide-wires S_1 and S_2 provide for a continuous variation between these steps, while r_1, r_2 and s_1, s_2 serve to adjust, once for all, the 20 deg. cent. resistance of either arm to exactly 250 ohms.

Errors Due to Inaccurate Adjustments. If the direct current i splits into two parts, i_i in the instrument side, and i_n in the resistance side of the bridge, then the d-c. torque, being produced by i_i only, will be have the value

$$T_{dc} = K \,.\, i_i^2 \qquad (10)$$

where K is a certain instrument constant.

If the splitting is correct, so that i_i is just one half of i, we have

$$T_{dc}' = \frac{K\,i^2}{4} \qquad (10a)$$

On the other hand, if the alternating current I splits in two parts I_1 and I_2, the a-c. torque will be

$$T_{ac} = K \,.\, |\,I_1\,I_2\,| \cos\,(I_1, I_2) \qquad (11)$$

or, when I_1 is equal to, and in phase with I_2,

$$T_{ac}' = \frac{K\,I_0^2}{4} \qquad (11a)$$

where the r. m. s. value of the current I is denoted by I_0.*

Now, when the compensator shows zero deflection,

$$T_{ac} = T_{dc} \qquad (12)$$

and thus

$$i = I_0 \qquad (13)$$

*We consider here only the case of a purely sinusoidal current. The effect of harmonics has been to some extent treated by Gibbon[5]. Just as the ordinary electro-dynamometer, this instrument will give r. m. s. values, independent of wave-form. The analysis given above may be applied to each and any of the components if the measured current is of a complex wave-form.

The direct current i is therefore exactly equal to the r. m. s. value of the alternating current, independently of the constant K. However, errors may here occur, either by a misadjustment in the d-c. splitting, so that (**10a**) is not true, or by a faulty a-c. adjustment, causing a deviation from equation (**11a**).

If a misadjustment is made in the d-c. splitting condition (**4**), since $i_i + i_n = i$, we may write

$$\begin{cases} i_i = \dfrac{i}{2}\,(1 + \epsilon) \\[2ex] i_n = \dfrac{i}{2}\,(1 - \epsilon) \end{cases} \tag{14}$$

The d-c. torque then will be

$$T_{dc} = \frac{K\,i^2}{4}\,(1 + \epsilon)^2 \tag{15}$$

and an error

$$\Delta\,T_{dc} = T_{dc}'\,(2\,\epsilon + \epsilon^2) \tag{16}$$

will result.

If a similar misadjustment is made in the a-c. splitting condition (5), the relative error ϵ may be a

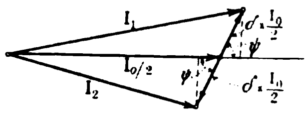

Fig. 4—An Error in the A-C. Splitting Condition

vector, say $\delta \angle \Psi°$, and we get, in accordance with Fig. 4, and in analogy with (**14**):

$$\begin{cases} I_1 = \dfrac{I}{2}\,(1 + \delta \angle \Psi) \cong \dfrac{I}{2} \times (1 + \delta \cos \Psi) \\ \qquad\qquad \angle \tan^{-1}(\delta \sin \Psi), \\[2ex] I_2 = \dfrac{I}{2}\,(1 - \delta \angle \Psi) \cong \dfrac{I}{2} \times (1 - \delta \cos \Psi) \\ \qquad\qquad \angle - \tan^{-1}(\delta \sin \Psi). \end{cases} \tag{17}$$

The a-c. torque then will be

$$T_{ac} = \frac{K\,I_0^2}{4}\,(1 + \delta \cos \Psi)\,(1 - \delta \cos \Psi) \times \cos\,[\,2 \tan^{-1}(\delta \sin \Psi)\,] \tag{18}$$

and the absolute value of the error

$$|\,\Delta\,T_{ac}\,| = T_{ac}'\,(1 - \delta^2 \cos^2 \Psi)\,(1 - 2\,\delta^2 \sin^2 \Psi + \ldots)\,]\,| \tag{19}$$

We may therefore safely put

$$|\,\Delta\,T_{ac}\,| < 3\delta^2 . T_{ac} \tag{20}$$

Expressing eq. (**16**) and (**20**) in words, we may accordingly say, that a misadjustment of 1 per cent in the d-c. splitting conditions will give rise to a little more than 2 per cent error in the current equality, while a misadjustment of 1 per cent in size in the a-c. balance will affect the comparator reading by less than 3 parts in ten thousands. Considering that each step in the dial rheostats represents 1 per cent of R_1, that is, 0.5 per cent of the sum $R_1 + N_1$, the conclusion is that even such a rough misadjustment as one full step on these rheostats will give an error of measurement that is less than 0.0075 per cent. It is therefore permissible to adjust once for all $R_1 = R_2$ and only occasionally check this adjustment. On the other hand, the condition $R_1 + R_2 = N_1 + N_2$ must be very accurately maintained and since R_1 and R_2 are liable to change with room temperature, and with load, facilities must be provided for checking this adjustment at any time during the use of the comparator. In order not to interfere with the adjustment $R_1 = R_2$, the dial rheostats while adjusting the condition $R_1 + R_2 = N_1 + N_2$, should always be

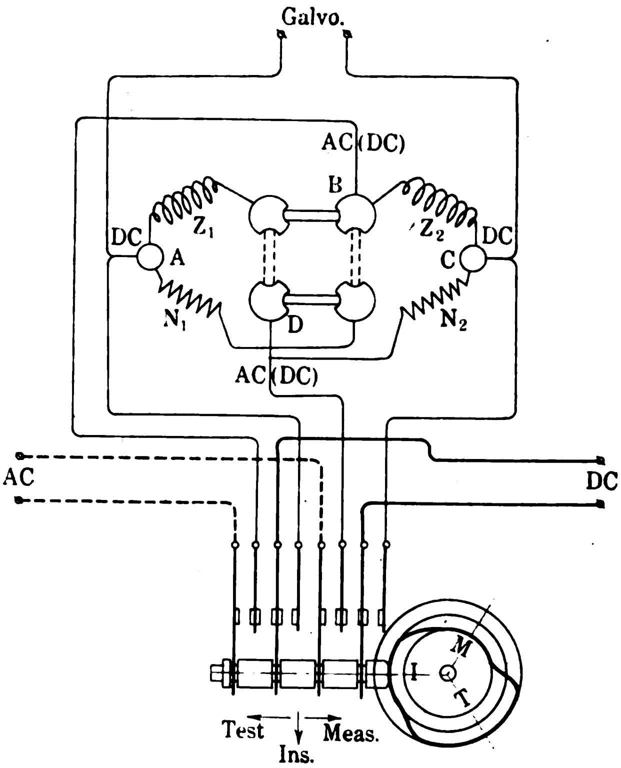

Fig. 5—Plug-contacts and Selector Switch

moved symmetrically, and for similar reasons the runners on the slidewires S_1 and S_2 are mechanically interconnected.

Manipulation. To facilitate the resistance-adjustments the bridge-arms are connected to four plug-contacts, as indicated in Fig. 5, and a four-pole double-throw contact-spring switch is provided, whose mechanism is schematically shown in the figure. For the sake of clearness the contact-plugs are drawn as interconnecting bars. The full-drawn bars indicate the working position. With the switch in position M (Measurement) the bridge will then appear as shown in Fig. 3.

By turning the switch over to position T (Test), direct current is impressed across terminals A and C in Fig. 3, while the a-c. system is disconnected. The

condition $R_1 = R_2$ then may be adjusted to by means of a d-c. galvanometer, as indicated in Fig. 6 a.

If the connecting plugs are changed to the position indicated by dotted bars in Fig. 5, the bridge will take the form of Fig. 6 b. If a balance in the d-c. galvanometer is obtained by increasing or decreasing R_1 and R_2 by equal amounts, the following relation will hold:

$$R_1 : N_1 = N_2 : R_2. \qquad (21)$$

For reasons given above, we have allowed, in the previous adjustments, a certain inaccuracy, so that R_1 may not be exactly equal to R_2. If we denote by R' the arithmetical mean of R_1 and R_2, the condition of exact d-c. splitting may be written

$$2\,R' = N_1 + N_2, \qquad (22)$$

while the two resistances will be, say,

$$\begin{cases} R_1 = R'\,(1 + k), \\ R_2 = R'\,(1 - k). \end{cases} \qquad (23)$$

Introducing these notations in eq. (**21**) we get at a balance

$$R'\,(1 + k) \times R'\,(1 - k) = N_1 N_2, \qquad (24)$$

or

$$R'^2 = \frac{N_1 N_2}{1 - k^2} \qquad (25)$$

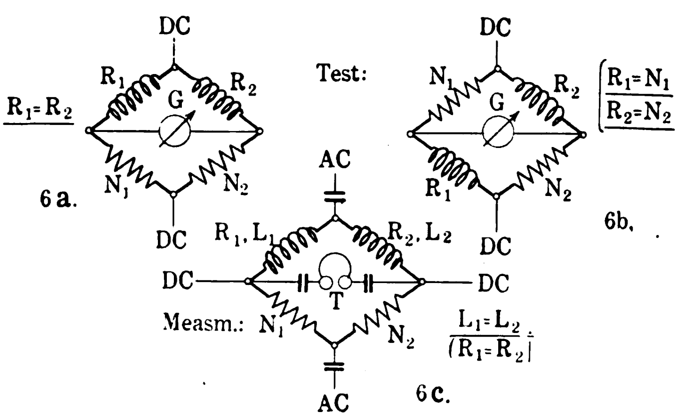

Fig. 6, a, b, c—Connections for Measurement and Test

Therefore, even if an exact adjustment of the bridge in Fig. 6 b is obtained, there may still remain a slight deviation from eq. (22). If the two resistances R_1 and R_2 are just equal, the deviation will vanish. In any other case, the relative error in R'^2 being k^2, there will be an error $\frac{1}{2}k^2$ in the adjustment of R', which results, by equation (**16**), in an error of measurement twice as great, or k^2. Allowing a deviation $2\,k$ of 1 per cent between R_1 and R_2, we shall have $k = 0.005$, and the resulting error in measurement—25 parts in a million. Although the described method of adjusting the instrument does not in general lead to a perfectly correct adjustment, the errors will in any practical case be entirely insignificant, and the method may therefore be recommended because of its convenience.

The a-c. balance condition $L_1 = L_2$ may easily be arrived at by use of a pair of head-phones, with the instrument connected for measurement, as Fig. 6 c suggests. In reality the adjustment was obtained by slightly changing the position of one field coil in the dummy with respect to the other, whereby the total inductance of the arm was varied. It has been experimentally ascertained that such an adjustment, made at a low frequency, will hold true at least up to 2500~.

The one and only adjustment that has to be made, or tested, during run, therefore, is represented by Fig. 6 b. It is to be noted here, that the necessity of using a d-c. galvanometer for this adjustment does not in general imply any appreciable complication, since a d-c. potentiometer is usually employed for the accurate determination of the compensating direct current, and a galvanometer is therefore already included in the outfit.

Correction-Method. It is possible, by making double use of this potentiometer, to avoid all adjustments during run and replace them with arithmetical operations representing experimentally determined corrections to be applied to the measured values of direct-current strength, in order to obtain the actual alternating-current value at balance when condition (4) is not fulfilled. The corrections may be determined by plugging the bridge as Fig. 6 b shows, and measuring with potentiometer the potential difference between the two terminals marked "Galvo." This potential difference, v, is the difference between the drops along R_1 and N_2:

$$v = \frac{R_1\,(R_2 + N_2) - N_2\,(R_1 + N_2)}{R_1 + R_2 + N_1 + N_2}\ .\ i. \qquad (26)$$

Putting $N_1 = N_2 = N$ and using equations (**23**), we obtain

$$v = \frac{R'^2\,(1 - k^2) - N^2}{2\,(R' + N)}\ .\ i \qquad (27)$$

$$= \tfrac{1}{2}\left[\, R' - N - \frac{R'}{N + R'}\ .\ k^2 R' \,\right] .\ i \qquad (27a)$$

From equations (**10** a) and (**11** a) may be derived a general expression for the true alternating-current strength I_0:

$$I_0 = 2\,{}_{a}i = i \times \frac{2\,(N_1 + N_2)}{R_1 + R_2 + N_1 + N_2}\ ; \qquad (28)$$

whence, in the new notation.

$$I_0 = i - i \times \frac{R' - N}{R' + N}\ . \qquad (29)$$

Inserting the value of $R' - N$ from eq. (**27** a) we get

$$I_0 = i - \frac{2\,v}{R' + N} - k^2 \left(\frac{R'}{R' + N}\right)^2, \qquad (30)$$

From the form of eq. (**29**) it is evident that v must be counted positive when R' is greater than N, which is the case that would occur in practise, due to heating effects in the coils. The direct current is then greater than the alternating current and the correction consequently negative.

For all practical purposes R' may be written $= N$

in the correction term, and the last term may be neglected. The result then is the following extremely simple formula:

$$I_0 = i - \frac{v}{N} \ . \tag{31}$$

A more exact formula (the k^2-term only neglected) is

$$I_0 = i - \frac{v}{N + v / a} \tag{31a}$$

As a rule, however, (**31**) may be used, and the correcting becomes very simple. We have here neglected the change in i which may occur when the bridge is plugged over from the position 6 c to 6 b. Clearly, such a change will be very small and affect only the correction term and to a very small extent.

In cases where the comparator is used with varying current strength of such values that the heating effects are appreciable, the correction method probably will be much handier than the regular adjustment method. In determining the corrections it becomes unnecessary to await steady thermal conditions. Each observation on the comparator may instead be interpolated between two determinations of the correction, the mean of which is used.

Precautions. In the use of a dynamometric comparator of non-astatic type there are certain precautions to be taken so as to avoid disturbances from the earth's field. The instrument is conveniently set up with the plane of the moving coil perpendicular to the horizontal component of magnetic intensity. A compensating magnet, suitably placed, often does good service for eliminating the last trace of disturbance. In the control-box, four plug-contacts are provided for reversing the moving coil. The instrument may be tested for constant and alternating magnetic stray fields by passing, correspondingly, direct respectively alternating current through the moving coil, and observing, if any change of zero occurs upon reversal of the moving coil. During this test the instrument field-coil arm s opened by removing one of the bridge plugs.

When the comparator deflects, its effective inductance, which is normally about 80 millihenrys, changes quite appreciably. In work with resonant circuits an instability may therefore occur. Such instability may always be eliminated by reversing the moving coil. When the instrument inductance must be accurately known, the coils are so adjusted that their axes form a 90 deg. angle in the zero or balanced position. Perpendicularity may be reached by passing a relatively strong alternating current through the field coils, and turning the suspension until no deflection occurs upon short-circuiting the moving coil with one of the reversing plugs.

Accuracy and Limitations. The foregoing analysis clearly shows that the bridge-adjustments necessary for correct indications in the comparator easily may be carried to a point where the results have at least a four-figure accuracy. When the instrument is employed to measure an alternating current of 20 milliamperes, a change in current of 1 per cent causes a deflection of 65 mm. (2¼ in.) at a one meter scale distance. At lower currents the instrument is less sensitive, but a comparator may be designed for any current range by choosing the proper number of turns in the coils, etc. Twice the sensitivity would be obtained in an astatic double-instrument, as suggested above, and by building the comparator in the form of a torsional balance an extremely high sensitivity could be reached, permitting the accurate measurement of alternating currents counted in microamperes.

An upper limit is put to the current range of any particular instrument by the heating effects in the coils, and at lower frequencies by mechanical vibrations in the moving system, probably due to unbalanced magnetic pull. The useful frequency range is limited by the high inductance, and by disturbances due to capacity in the coils.

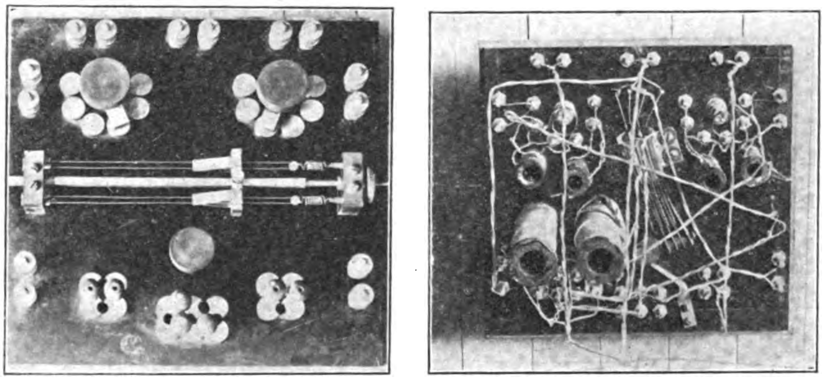

Fig. 7, a & b—Showing the Control-box
a is a view of the top, and *b* shows the inside of the box, seen from below

It is interesting to note, that since this form of comparator probably represents the most sensitive and accurate method of determining the strength of alternating currents of the order of magnitude in question, which is known at the present time, there appears to be no way of experimentally checking its accuracy by comparison with other instruments. It is to be expected that at higher frequencies errors will occur to capacity effects in the coils, but attempts to ascertain the existence of such deviations by direct comparison with an accurate thermocouple gave negative results for frequencies up to 2500 p. p. s.

The Design of the Control Box. Fig. 7a shows the appearance of the control-box as viewed from above, and Fig. 7b is a picture of the interior of the box. The two dials and slide-wires on the top are easily identified, and to the left are the four plug contacts for the bridge while the four plug contacts to the right serve for the reversal of the moving coil. The six plugs in the middle of the lower edge are intended for connection to a constant-impedance shunt on the moving coil, a refinement which did not appear necessary with the

instrument as built, since it could well stand 90 deg. deflections without damage to the sturdy suspension.

Practical Applications of the Dynamometrical Comparator. Fig. 8 will give an indication how the comparator may be used for the accurate calibration of a shunted thermocouple at various frequencies. A d-c. potentiometer is used for determining the thermo-e.m.f. of the couple, and also, by observing the drop across a standard resistance, for measuring the compensating current in the comparator. The same potentiometer may be employed, in the correction-method, for determining the quantity v (**31**) and the instrument correction.

An interesting suggestion regarding the possibility of increasing the range of the instrument was made by Mr. Varley[7] who proposed to measure heavy alternating currents by means of much weaker direct currents. For this purpose auxiliary d-c. field coils would have to be arranged outside the bridge proper, so as to aid the ordinary field coils in building up the counter-

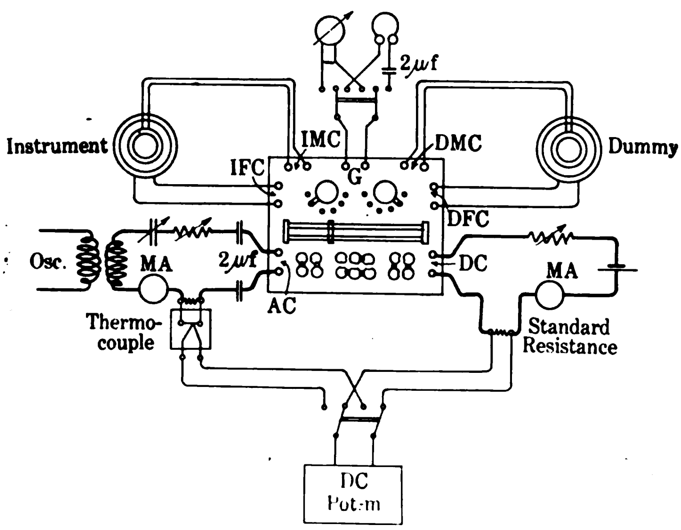

Fig. 8—The Dynamometrical Comparator and its Control Box Employed for Calibrating a Shunted Thermocouple

acting d-c. torque. The instrument would then have to be calibrated, and the very important feature of automatic equality between a-c. r. m. s. value and compensating d-c. strength, without reference to instrument-constants, would have to be given up.

Until very recently there was no need, at least not for work within the telephonic frequency-range, for an alternating-current measuring instrument of any such accuracy as may easily be obtained by this dynamometrical comparator. Since there was no sufficiently constant source of alternating current available, current measurements of high accuracy were of no use. However, with the advent of the three-electrode high-vacuum tube oscillator as a laboratory source of audio frequency current, the situation has changed. When fed from storage batteries the triode oscillator gives an output of four-figure constancy to amplitude as well as to output frequency. The need for an instrument of comparable accuracy has thus arisen, and the differential dynamometer will no doubt find many applications in the new technique of accurate alternating-current measurements which is growing up on the basis of the triode oscillator as a source of current. When used for instance in conjunction with an alternating-current potentiometer for adjusting the potentiometer current to a certain fixed value, the manipulation of the comparator is very simple. In such a case it is evidently not necessary to use a regular potentiometer with the outfit, but a once for all adjusted resistance and a standard cell, will equally well serve for checking of the compensating current.

Summary

1. Due to inherently lower precision of alternating-current measurements, more accurate results are often obtained in transferring, by means of a comparator, the alternating-current measurements into direct-current measurement of related type.

2. A dynamometrical comparator, acting as a differential dynamometer, with its coils connected as two arms of a Wheatstone bridge, was constructed by Mr. C. O. Gibbon, in the Electrical Engineering Research Division of the Massachusetts Institute of Technology.

3. Even in its first experimental form this instrument proved capable of a most remarkable sensitivity and accuracy.

4. In the hands of the present writer, the dynamometrical comparator has reached a second stage of development. By the introduction of a special control-box the manipulation has been much simplified. Means have also been provided for the quick and accurate adjustment of the comparator-ratio at any time during use of the apparatus for measuring purposes.

5. An analysis of the main sources of error shows that the accuracy of the instrument is extremely high, the readings being reliable to within a few hundredths of a per cent.

6. The comparator has very successfully been applied to various types of practical current measurements. In fact, this instrument, in conjunction with a direct-current potentiometer, seems to offer the most accurate means which are known at the present time, for the determination of the r. m. s. value of alternating currents of the order of 5 to 50 milliamperes, at frequencies up to about 2000 p. p. s.

7. Already in its present form the dynamometrical comparator thus has proved to be a very useful laboratory instrument. Certain definite suggestions are made, however, concerning further improvement in the apparatus.

PACIFIC COAST CONVENTION

The Ninth Annual Pacific Coast Convention of the A. I. E. E. will be held in Portland, Oregon, July 21-24, 1920, under the auspices of the Portland Section. Headquarters at the Multnomah Hotel.

A program has been arranged as follows:

Wednesday, July 21

9:30 A. M.

1. *Address* by President Calvert Townley.
2. *Factors Controlling the Design and Selection of Suspension Insulators*, by W. D. A. Peaslee, Electrical Engineer, Jeffery-Dewitt Insulator Company.

2:00 P. M.

3. *Unit Voltage Duties in Long Suspension Insulator Strings*, by Professor Harris J. Ryan and H. H. Henline of Leland Stanford Jr. University.
4. *Electrical Characteristics of the Suspension Insulator at the Higher Voltages*, by F. W. Peek, Jr., Consulting Engineer, General Electric Company, Pittsfield, Mass.

7:30 P. M.

Automobile tour over scenic boulevards of the city.

Thursday, July 22

9:30 A. M.

5. *Electrification of Railroads*, by Reinier Beeuwkes, Electrical Engineer, C. M. & St. P. Railroad.
6. *Bridge Methods for Alternating-Current Measurements*, by D. I. Cone, Engineering Dept., Pacific Telephone and Telegraph Company.

2:00 P. M.

7. *Sawmill Refuse, Fuel Oil and Pulverized Coal*, by Darrah Corbet, Chas. C. Moore and Company.

7:30 P. M.

General discussion on Institute Welfare.

Friday, July 23

9:30 A. M.

8. *Power Factor Correction on Distribution Systems*, by D. M. Jones, General Electric Company, Schenectady, N. Y.
9. *Use of Special Steels in Pressed Steel Transmission Line Fittings*, by L. R. O'Neill, Chief Engineer, Maryland Pressed Steel Company.

In addition to the presentation of the papers scheduled above the Convention Committee has arranged for various entertainment features including a Golf Tournament for the John B. Fisken Cup to start at 1 p.m. on Friday, a trip over Columbia River Highway starting at 2 p.m. on the same day and followed by a banquet at the Crown Point Chalet at 7 p.m.

Saturday, July 24

Tours of inspection to the steam and hydroelectric plants of the Portland Railway, Light and Power Company and the Northwestern Electric Company and to other points of interest in and around Portland are arranged for Saturday, July 24.

Special entertainment will be provided for the visiting ladies.

EDISON MEDAL PRESENTATION TO W. L. R. EMMET

A brief notice of the presentation of the Edison Medal to Mr. W. L. R. Emmet was given in the June JOURNAL which was published before the details of the meeting could be reported. The program consisted of addresses by Carl Hering, Chairman of the Edison Medal Committee; Past President, H. W. Buck; and the recipient, Mr. Emmet. Mr. Hering described the origin and history of the medal and said in part:

"In 1904 a group of twenty-four friends and former associates of Thomas A. Edison, forming an association known as the

W. L. R. EMMET

Edison Medal Association, initiated the thought of founding what was to be called the Edison Medal, for the purpose (as quoted from the Deed of Gift) 'of appropriately recounting and celebrating the achievements of a quarter of a century in the art of electric lighting, with which the name of Thomas Alva Edison is imperishably identified.'

"They subscribed to a fund of $5000 which is to be held in trust in perpetuity, and from the income of which a gold medal is to be executed, and a parchment certificate issued, which together with a part or the whole of the residue of this income, shall be awarded by a committee (to quote again from the Deed of Gift) 'to some one resident of the United States of America

and its Dependencies, or of the Dominion of Canada, for meritorious achievement in Electrical Science or Electrical Engineering or the Electric Arts, whenever in the judgment of said Committee a resident of either of said countries is properly deserving of such award.' The character of the achievement is to be stated on the certificate.

"This was thought by the founders and donors to be the most effective means to accomplish their object, which was that this Edison Medal (to quote again from the Deed of Gift) 'should, during the centuries to come, serve as an honorable incentive to

scientists, engineers and artisans, to maintain by their works the high standard of accomplishment set by the illustrious man whose name and features shall live while human intelligence continues to inhabit the world. * * * No change shall ever be made in such name."

"In the Deed of Gift the American Institute of Electrical Engineers agreed to undertake the awarding of this medal in accordance with the wishes of the donors, which function is characterized in that Deed as an 'extremely difficult and delicate task.' The Institute does so through a committee of 24 of its

members. The decision of this Committee is final, hence its responsibilities are great, and the rule has been to award this medal once a year. The medal itself was designed by James Earle Frazer; on its obverse side there is a portrait of Thomas A. Edison, and on its reverse side an allegorical conception entitled, 'The Genius of Electricity Crowned by Fame.'

"I presume that I am not divulging any confidential information of this committee in making the statement, which is so creditable to our country, that the 'difficulty' of its task mentioned in the Deed, has not been to find one who is worthy of the medal, but rather to decide which one of several shall be its choice for that year; let us hope, to the credit of this country, that this will continue to be the only difficulty of this Committee."

Mr. Harold W. Buck gave an account of Mr. Emmet's achievements in the Engineering field beginning with his entrance into the Navy in 1881. "After staying in the Navy for about two years, he went into business, and was occupied with various engineering and architectural work until the year 1887, when he joined the Sprague Electric Company, which was then coping with the electric railroad development in Richmond and later on in Harrisburg and other cities throughout the country.

"Mr. Emmet acted as Assistant Engineer of this Company and his first job was to go to Harrisburg to get the electric railroad system in that city working. He then went, in the same capacity, to Cleveland, Wichita and Kansas City, where he installed electric railway apparatus.

"In 1889 and 1890, he was sent to Pittsburgh, for the Sprague Electric Company, to oversee that installation, which was one of the largest electric railroad installations which had been made up to that time. There were 60 equipments, which at that time, was a very large installation.

"Mr. Emmet, with his characteristic determination, tackled this job, rewound the motors, reinsulated the coils, and devised new methods of attaching the brushes—devised and invented this method, which was really quite an historic development in electrical engineering, and he invented a new system of insulation for armature coils.

"In 1890, Mr. Emmet went with the Westinghouse Electrical Manufacturing Company for a short time, and in 1891, he associated himself with the R. D. Nuttall Company in Pittsburg, which was, at that time, developing electric railroad appliances. Mr. Emmet invented and patented several trolley devices and other electric railway supplies that were very successful.

"From there he went to Buffalo, as Engineer of the Buffalo Railway Company, and in 1891, he went to Chicago as the District Engineer of the Edison General Electric Company, which at that time had been formed, and he was engaged on construction work. In 1892, Mr. Emmet was transferred from the Chicago office to the New York office of the Edison General Electric Company, and started in there as engineer of the Foreign Department. From that position he was transferred to be engineer of the Lighting Department, and his most important professional work commenced at that time."

Mr. Buck then described at some length Mr. Emmet's work in the development of electric lighting, alternating-current distribution, air-blast transformers, oil circuit breakers, cable and generator insulation, steam turbines, electric ship propulsion, and his most important development, the mercury turbine, on which he is now engaged.

The Edison Medal and certificate of award were then presented to Mr. Emmet by President Townley, to which Mr. Emmet responded, expressing his appreciation of the honor conferred upon him. He also gave an interesting account of some of the more important activities of his career.

ANNUAL REPORT OF THE BOARD OF DIRECTORS

FOR THE YEAR ENDING APRIL 30, 1920

The annual report of the Board of Directors of the A. I. E. E. was presented at the annual business meeting of the Institute held in New York on Friday evening, May 21st, 1920.

This report consists of a brief summary of the principal activities of the Institute during the year, including abstracts of various reports submitted by officers and committees, covering their respective branches of work. Inasmuch as most of the matters of importance referred to in the report have been, or will be, covered in much more detailed form in the JOURNAL, the report will not be published in full herein, but any member

of the Institute may obtain a pamphlet copy upon application to the Secretary of the Institute.

The Board of Directors held ten regular meetings during the year; five of these were held in New York, one at the Lake Placid Club, N. Y., in June; one in Philadelphia in October; one in Chicago in January; one in Pittsburgh in March, and one in Boston in April; one Executive Committee meeting was held on April 27, 1920.

During the year President Townley attended many Institute and Section meetings including the Annual and Midwinter Conventions and meetings in Boston, Chicago, Detroit, Milwaukee, New York, Philadelphia, Pittsburgh, St. Louis, Schenectady and Toronto.

The report contains ample indication that the numerous committees of the Institute have resumed their pre-war activities. The increasing interest in the Institute's work is indicated by the large increase in membership during the year. With the demobilization of the army and navy completed, and industry returned to a peace basis, engineers are turning their attention to the zealous pursuit of their profession, which probably accounts largely for the fact that 2033 applications for membership were received during the year, which exceeds by 437 the number received during the previous year. The following tabulation indicates the present membership, and the additions and deductions during the year:

	Honorary Member	Fellow	Member	Associate	Total
Membership, April 30, 1919.	6	489	1467	8290	10,252
Additions:					
Transferred.....	....	18	106	....	....
New Members Qualified......	....	6	100	1717	....

Membership April 30, 1920........	6	498	1617	9224	11,345

Net increase in membership during the year.......................1093

The number of Sections has been increased during the past year by the addition of those at New York, Worcester, Mass., and Providence, R. I., and the number of Student Branches has been increased by the addition of Branches at the University of Wisconsin, and the School of Engineering of Milwaukee. The tabulation below indicates that the activities of the local organizations have returned to a condition corresponding to that prior to the war.

	For Fiscal Year Ending

The Finance Committee's report together with the General Balance Sheet and detailed Financial Statements of the certified public accountants who audited the Institute books are included in the report, and show that there has been a deficit of $3333.31 in the Institute's financial operations during the year; which, however, is considerably less than the original estimated deficit.

The reports of the Meetings and Papers Committee and the Publications Committee which were abstracted in the Directors' report are published in full herewith.

ANNUAL REPORT OF THE MEETINGS AND PAPERS COMMITTEE

FOR YEAR ENDING APRIL 30, 1920

The Meetings and Papers Committee has held a meeting every month except July and August. These meetings have been well attended and marked by much interest and discussion. A very large number of papers has been offered to the committee in the last year, more than could possibly be presented at the regular meetings of the whole Institute.

In order to make an opportunity to bring these papers before the members the M. and P. Committee recommended to the Board of Directors that the Chairman of each Section be made ex-officio a member of this committee in order that the Sections might be kept informed of the papers available and have a representative to ask for the assignment of appropriate papers for Section Meetings. The Board approved this suggestion and now each Section Chairman receives each month a list of papers available and is encouraged to ask for papers for presentation before the Section. So far the Sections have not taken full advantage of this arrangement.

The Committee has also found it advisable to recommend to the Publications Committee a number of papers that were of general interest but which could not be scheduled for meetings for lack of opportunity. A number of papers have thus been published without presentation at meetings.

In a great number of cases in the last year a Technical Committee has taken charge of a whole session or meeting of the Institute and presented a group of papers by different authors, all dealing with the same subject but from different points of view. The popularity of this scheme is one cause for the large number of papers presented.

Three conventions were held during the past year as follows:

The thirty-fifth Annual Convention at the Lake Placid Club, Adirondacks, New York, June 24-27, 1919.

The Pacific Coast Convention at Los Angeles, California, September 18-20, 1919.

The Mid-Winter Convention in New York, February 18-20. 1920.

Eight other Institute meetings were held during the year:, four in New York, and one each in Philadelphia, Chicago, Pittsburgh and Boston.

At the Conventions and other meetings referred to above, there were 52 papers presented upon various subjects as follows:

Traction 6, Electric Machinery 2, Power Stations 4, Electro-Physics 5, Standards 1, Electro-Chemistry 6, Protective Devices 3, Instruments 4, Lighting 5, Telephone and Telegraph 6, Transmission and Distribution 5, Miscellaneous 5.

REPORT OF THE PUBLICATION COMMITTEE

FOR THE YEAR ENDING APRIL 30, 1920

The Publication Committee was established for the first time during the present year by an amendment to the By-laws, in order to carry into effect the recommendations of the Development Committee relating to the Institute publications, as approved by the June 1919 Convention and subsequently by the Board of Directors. This committee has supervision of the monthly JOURNAL and the annual TRANSACTION of the Institute;

the functions of the former Editing Committee have been incorporated with those of the new Publication Committee.

The chief activity of this committee has been to put into effect the recommendation of the membership of the Institute that the monthly Proceedings be enlarged both as to scope and physical size and that it should serve as a medium of much more general information for the membership in addition to the customary Institute papers. This change was not easy to make during the past year, due to existing conditions of the publishing and related industries, including labor troubles and shortage of supplies. The change was inaugurated, however, with the issue of January 1920 and the committee submits the five numbers already published as a part of this report.

The committee is endeavoring to supervise the contents of the successive numbers so that the topics and branches of the profession represented will be diversified and so that in a reasonable sequence of numbers every interest will have been represented. The enormous increase in the cost of paper, printing and engraving has made it necessary for the committee to supervise its expenditures carefully in order to keep within the available funds, and therefore it has not yet been possible to do all that was hoped for and desired.

The appropriation for publications for the present fiscal year is 50 per cent greater than for any preceding year, thus more of the benefits of the Institute are being given directly to the membership in the form of publications than ever before, and this has been accomplished without any increase in the dues.

The committee wishes to express its appreciation of the encouragement it has received in the large number of unsolicited letters written by individual members expressing their approval and commendation of the new JOURNAL.

THE FEDERATED AMERICAN ENGINEERING SOCIETIES ORGANIZE

TO REPRESENT THE PROFESSION IN MATTERS OF COMMON INTEREST IN NATIONAL AND STATE AFFAIRS

In response to the call issued April 19, 1920 by the Joint Conference Committee representing the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, about 140 delegates representing 71 societies, having an aggregate membership of over 110,000, convened in Washington, D. C., June 3-4, 1920.

The Conference was called to order by the temporary Chairman, Richard L. Humphrey, Chairman of the Joint Conference Committee who outlined the history of the movement of which the meeting was the culmination, and sounded the keynote for the Conference.

An address of welcome on behalf of the District of Columbia and of the Washington Engineers, was delivered by Lt. Col. Charles W. Kutz, U. S. A., Engineer-Commissioner of the District of Columbia, which was responded to by the temporary Chairman.

Organization was effected through the election of Calvert Townley, Chairman, and John C. Hoyt, Secretary.

The following resolutions introduced by Gardiner S. Williams, embodying the fundamental principles of the comprehensive organization recommended by the Joint Conference Committee, were debated for a considerable portion of the morning session on June 3d:

RESOLVED, That it is the sense of this convention that an organization be created to further the public welfare wherever technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions.

RESOLVED, that it is the sense of this convention that the proposed organization should be an organization of societies or affiliations and not of individuals.

They were finally adopted without a dissenting voice, the roll call showing 121 delegates, representing 53 societies, voting in the affirmative; 8 delegates representing 5 societies present but not voting; and none voting in the negative.

Chairman Townley announced that the Joint Conference Committee had endeavored in all possible ways to facilitate the work of the Organizing Conference so as to conserve time and with this in view he offered the following suggestions for Committees:

Committee on Constitution and By-Laws, to deal with the form of the proposed organization embodied in a constitution and bylaws, to which the Joint Conference Committee had given consideration and would offer for the guidance of the proposed committee, the results of its deliberations.

Committee on Resolutions to which could be referred important resolutions of the Conference, for consideration and report.

Committee on Program to consider the program arranged by the Joint Conference Committee and make any changes or modifications which in its judgment were necessary.

The addresses by Arthur P. Davis, Philip N. Moore and Leroy K. Sherman, scheduled for the morning session were presented at the afternoon session and the remainder of the program was completed.

The report of the Committee on Program was presented by its Chairman, Robert H. Fernald. This report approved the program as prepared by the Joint Conference Committee, with the exception that it was recommended the report of the Committee on Resolutions, scheduled for presentation at the Friday evening session, be made an order of business for 4:30 p. m. at the Friday afternoon session. The report was unanimously adopted.

The evening session was held at the New Willard Hotel, and interesting addresses were presented by Homer L. Ferguson, James H. McGraw, and George Otis Smith. These were followed by a smoker under the auspices of the Washington Society of Engineers and its affiliated organizations.

The report of the Committee on Constitution and By-laws was presented by its Chairman, Richard L. Humphrey, at the Friday morning session. The Committee reported on the resolutions that had been referred to it by the Conference, and its recommendations were approved by the Conference.

Mimeographed copies of the proposed Constitution were distributed; it was then read by the Chairman and considered paragraph by paragraph; some minor modifications were made and the Constitution unanimously adopted. The vote showed 90 delegates, representing 57 societies, present and voting in the affirmative; none voting in the negative: 27 delegates refraining from voting because of instructions from the Societies they represented, limiting their power.

Mr. F. M. Feiker speaking for fourteen representatives of technical papers in attendance at the Conference, was recognized by Chairman Townley and stated that these technical press representatives were extremely interested in the proposed organization and wanted to aid the movement through publicity and in other ways and with the view of bringing about a close affiliation between the representatives of the press and the new organization, he offered an amendment to the Constitution providing for publicity which after some discussion was referred to the Committee on Constitution and By-laws.

At the afternoon session the Committee on Constitution and By-Laws reported on the resolution offered by Mr. Feiker at

the morning session, and its recommendation that the following be inserted in the Constitution, as Article X was agreed to.

"This organization stands for the principle of publicity and open meetings under such regulations as may be provided in the By-Laws."

The Committee further recommended that there be inserted in the By-Laws, the following:

Chap. IV. Publicity

Sec. 1. The privilege of attendance at all meetings of the American Engineering Council, of the Executive Board, and of Committees, when not in executive session, should be extended to any proper person, but this privilege does not extend the right to speak or vote. Any proper person shall have the right to inspect and make true copies of the official records of all meetings of the Council, the Executive Board, and the Committees.

Sec. 2. The Publication Committee may employ a Publicity Secretary whose duty, under the direction of the Executive Board, shall be to prepare and supply to the engineering, technical and general press, information concerning the Federated American Engineering Societies, or the engineering world, and to cooperate with the editors of engineering and technical publications in disseminating information in regard to the organization and its activities. The Publication Committee may appoint a cooperating board of engineering editors to counsel and assist in any or all of its activities.

Mimeographed copies of the By-Laws were distributed. The Chairman then read the By-Laws as thus amended, which were discussed and unanimously adopted without a roll call.

The Constitution and By-Laws as amended were referred back to the Committee for editing and will be printed and distributed at the earliest possible moment.

The Chairman of the Committee on Constitution and By-Laws stated it was the opinion of the Committee that there should be an ad interim Committee to carry on the work during the period following the adjournment of the Organizing Conference and the convening of the American Engineering Council and offered the following resolution, which was unanimously adopted:

That it is the sense of this Committee that the Joint Conference Committee should be entrusted with making provision for putting the conclusions of this Conference of Engineers into effect, and that we recommend to the Conference that Engineering Council be requested to carry on its work until the new organization has been established by all proper means to further the program of the new organization, and that the Conference recommends to the contributing societies that they continue supplying the funds required by Engineering Council until its work is taken over by the new organization.

Mr. O. J. Sterrett, delegate from the Detroit Engineering Society, stated that the Society that he represented had voted to join the new organization at its last meeting.

The delegates of the American Society of Mechanical Engineers, through their Chairman, L. P. Alford, stated that they had been sent to the Conference with power to act for their organization and announced that that Society pledged its membership in the new federation. Mr. Calvert Townley, President of the American Institute of Electrical Engineers, stated that he could predict with reasonable certainty that the Institute would also at an early date pledge its membership in the new organization.

The delegates of a number of other societies stated that while the matter would have to be referred back to the organizations which they represented for final action, it was their opinion that this action would be favorable.

The report of the Committee on Resolutions was presented by George G. Anderson and was unanimously adopted:

Major Bond, representing the Society of American Military Engineers, presented a brief outline of the work of this new organization and made an appeal to all American Engineers to become identified with the organization and thus aid by doing their bit toward keeping America prepared for future emergencies.

The afternoon session concluded with the adoption of resolutions of appreciation of the work done, in organizing the Federated American Engineering Societies by the Joint Conference Committee and by the Committee on Constitution and By-Laws which were extended by the Chairman Townley to Richard L. Humphrey the Chairman of both these Committees, and by Chairman Calvert Townley who presided over all sessions of the Conference.

The Conference finally adjourned Friday evening following addresses by Samuel M. Vauclain, President of the Baldwin Locomotive Works, Robert S. Woodward, President of the Carnegie Institution, James R. Angell, Chairman of the National Research Council, and an informal reception and smoker at which the delegates and guests of the Organizing Conference were the guests of the Washington Society of Engineers and the Affiliated Organizations.

The meeting of the Organizing Conference was thoroughly representative. National, Local, State and Regional Engineering Organizations, from Maine to California and from the Gulf to the Lakes had delegates in attendance. The gathering is unparalleled in the history of the engineering and allied technical societies of this country and marks a forward step in the history of these professions. The Conference had two distinct characteristics, the business sessions which moved smoothly and harmoniously, voicing the unanimous desire of the engineering societies of this country for a comprehensive organization as planned by the Joint Conference Committee; and the sessions at which addresses of an inspirational character were presented. The deliberations were characterized by great harmony and a form of organization, including Constitution and By-Laws, was adopted without a dissenting vote; if the attitude of the delegates in attendance reflects the spirit of the organizations they represent, it is evident there is a wide-spread and unanimous desire for some form of comprehensive organization that will represent the solidarity of these professions.

The Joint Conference Committee will send to various organizations, reports of proceedings in the Organizing Conference, including the inspirational addresses referred to and the Constitution and By-Laws that have been adopted. It will also send at a later date formal invitations to become members of the Federated American Engineering Societies and to send delegates to the American Engineering Council which is expected to hold its first meeting either during the latter part of October or the first part of November; the call for this meeting announcing the time and place will be sent in due course by the Joint Conference Committee.

The Joint Conference Committee feels that it reflects the unanimous judgment of the representative body of Engineers that attended the Organizing Conference in Washington when it states that at this historic meeting action of the greatest importance to the future of the engineering and allied technical professions was taken in the formation of a comprehensive organization that will represent these professions in a service dedicated to the city, state and nation.

The Joint Conference Committee strongly urges the engineering and allied technical societies of this country to take immediate action in the matter of becoming members, to appoint at an early date delegates to participate in the first meeting of the American Engineering Council and in all ways do their bit in making eminently successful the new organization which shall speak for these professions in all matters affecting the public welfare, where technical knowledge and engineering experience are involved, and on other matters of common concern to the public and to these professions.

The constitution, in accordance with the instructions of the conference, is now in the hands of an editing committee, and will be published later in its complete and finished form. The main features of the Constitution are as follows:

Membership. Membership is to consist of national, local, state and regional engineering and allied technical organizations and affiliations, classified as follows:

(1) National engineering and allied technical organizations.

(2) Local, state, or regional engineering or allied technical organizations other than local associations, sections, branches or chapters of national organizations.

(3) Affiliations consisting of local sections of national organizations, local engineering societies or clubs and local engineers.

Management. The management of the new organization is to be vested in a body known as the American Engineering Council and its Executive Board. This Council is to consist of representatives of member societies each of which shall be entitled to one representative for a membership of from 1 to 1000, and one additional representative for each additional thousand members or a major fraction thereof. This Council is to hold an annual meeting. The elected officers of the Council will be a president, to hold office for two years, four vice-presidents to hold office for two years, two to be elected each year, and a treasurer to hold office for one year. An Executive Board is also provided, to consist of thirty members of the Council, and this Board is to conduct the business of the new organization under the direction of the Council. The six officers selected by the Council are to be members of this Executive Board and the balance of twenty-four shall be selected by the National Societies and local, state and regional organizations according to districts. The president and secretary ofthe Council shall be, respectively, the chairman and secretary of the Executive Board.

Funds. The funds for the use of the new organization are to be obtained in the following manner: Each national member society represented on the Council is to contribute annually $1 50 per member. Each local, state or regional organization represented is to contribute annually $1 per member.

Local Affiliations and State Councils. The Council is empowered to encourage the formation of local affiliations to consider matters of purely local public welfare with which the engineering profession is concerned. It is also authorized to create state councils consisting of representatives of the local affiliations within the state. These councils are also for the purpose of considering matters of public welfare as associated more particularly with state matters.

The delegates appointed to attend the meeting on behalf of the A. I. E. E. were as follows: H. W. Buck (*chairman*), New York City; C. A. Adams, New York City; A. W. Berresford, Milwaukee, Wis.; John H. Finney, Washington, D. C.; James H. McGraw, New York City; L. F. Morehouse, New York City; E. W. Rice, Schenectady, N. Y.; L. T. Robinson, Schenectady, N. Y.; Samuel Sheldon, Brooklyn, N. Y.; C. E. Skinner, East Pittsburgh, Pa.; Calvert Townley, New York City; R. H. Dalgleish (*alternate*), Washington, D. C.; C. F. Lacombe, (*alternate*), Babylon, L. I.

FEDERATED AMERICAN ENGINEERING SOCIETIES ENDORSED BY ENGINEERING COUNCIL

Engineering Council has in numerous ways expedited the creation of a comprehensive, representative body to perform for the engineers of America in a larger fashion, such functions as Council has performed for the past three years. At its meeting in October, 1919, Council endorsed the general plan for a national engineering council, as outlined by the Joint Conference Committee of the Founder Societies. January 23, 1920, it assembled in joint meeting in Engineering Societies Building, the governing bodies of all its member societies and United Engineering Society, at which meeting the plan was given strong impetus. Through its Washington office, and otherwise, Council aided the Organizing Conference of Technical Societies, held June 3 and 4, in Washington.

At its regular meeting June 17, 1920, after hearing a report on the Organizing Conference, Engineering Council took the following actions:

VOTED: that Engineering Council heartily endorse the plan of organization of the Federated American Engineering Societies and the American Engineering Council, adopted by the Organizing Conference of technical societies in Washington June 3 and 4, and authorize its Executive Committee to proffer and perform on the part of Council such assistance as may be practicable in completing the work of the Organizing Conference and of the Joint Conference Committee of the Founder Societies in establishing the American Engineering Council.

VOTED: that Engineering Council authorize its Executive Committee to deal with any question of cooperation with the Joint Conference Committee of the Founder Societies, relating to the permanent organization of the Federated American Engineering Societies, which may come up during the summer.

VOTED: that the Secretary be instructed to invite to future meetings of Engineering Council delegates of the societies participating in the Organizing Conference in Washington, June 3 and 4, and editors of technical journals who may be interested.

JOINT MEETING OF FOUNDER SOCIETIES

A special joint meeting of the founder societies was held in the Engineering Societies Building on May 26, 1920, having for its subject the value to the Engineering Profession of a liaison between the Engineering Societies of Russia and of America, to further cooperation for the benefit of the engineers of both countries. Mr. Walter N. Polakov, Member, American Society of Mechanical Engineers, presided, and the speakers were Mr. N. A. Stephanoff, President, Russian Society in America, and Mr. W. F. Dickson, Director, Russian Singer Company. An illustrated lecture upon the resources of Russia was given by Dr. J. M. Goldstein, Professor of Economics, Moscow University.

Mr. Stephanoff's address was on the subject of the Russian engineer as a personality. From the three viewpoints of training, social situation, and psychological characteristics, he discussed briefly his fellow engineers. A few of the high points he touched upon follow:

In Russia, engineers were divided into two classes: that of the engineers who had been graduated from the high technical schools and received their diplomas, which can be compared to the Massachusetts Institute of Technology; these were termed "Graduate Engineers." The second class composed the practical engineers from special technical colleges.

Every specialty of engineers had its own societies, grouping all its members, as the Government of the old Regime was strongly opposed to any scheme of one large union, which would have united all the engineers of Russia. However, within two months of that Government's overthrow, one All-Russian Engineers Union was formed, which admitted in its ranks, not only the graduate engineers but also the practical, regardless of political opinion as this Association, which counted about 60,000 members, was a purely professional organization.

My second point was the social situation of the Russian engineer. Sixty per cent of Russian engineers made their careers in the government administration, which provided them becoming uniforms and not a few glittering decorations. They were always deprived of their initiative by the government. About 10 per cent, let us say, allowed their training to become unproductive, and the remaining 30 per cent found their way into industry where they had to compete with foreign, and especially German, engineers, and it is only during the fifteen years which preceded the war that they really began to come into their own and occupy the first place in their own country.

I will now pass on to the third point; that of the psychological characteristics of the Russian engineer:

First come his disinterestedness and absence of selfish aims in his work. I can best illustrate this by mentioning that during my 22 years of experience in Russia, I never heard of one industrial engineer having made money.

The Russian engineer's special ability for construction had, as you know, attracted the attention to the famous Professor Bach, whose motto was: "Less Invention, More Construction." In addition shall I term as a peculiarity the Russian engineer's belief that, independently from any political point of view, the first place belongs to men, the second to animals, and the third to machines, contrary to the general practise ascribing the first place to machines, the second to animals, and oftentimes no place at all for men?

Mr. Dickson spoke on Russian achievements ine ngineering among which he included the following:

In the field of bridge building some very fine work has been accomplished. The suspension bridge across the Dnieper at Kiev, the bridges over the Volga at Syzran and Yaroslavl, the Palace Bridge over the Neva at Petrograd—all rank high among similar structures in this and other countries.

The great Siberian Railway stretching from the Gulf of Fin-

land to the Pacific Ocean and linking together Petrograd and Vladivostok, cities almost exactly five thousand miles apart, can be compared very favorably with our own transcontinental lines. The skill displayed by the Russian engineers in spanning the wide Siberian rivers and in piercing, as I remember it, forty-two tunnels through the rocky cliffs bordering the southern shore of Lake Baikal, situated about halfway across Siberia, is something engineers of any nationality might be proud of.

In a museum at Nijni-Tagil there is, or was, preserved a steam engine built by a mechanic named Polzunoff for his own use for mining purposes in the Ural Mountains, which is credibly stated to have antedated, by a few years, James Watt's first steam engine (1765). It was in use for over a hundred years.

In the realms of electricity Russia has not lagged behind. Those of us who are still only middle aged will remember the invention of the Russian engineer Yablokoff of the arc light. I am not prepared to say that his was the first application of the arc for lighting purposes, but if it was not actually the first, it was amongst the earliest and most practical and was an independent invention. Lodegin produced an incandescent lamp at a time when electricity as a means of lighting was just beginning to be thought of. Dolevo-Dobrovokski developed the theory and practical application of the three-phase current.

The Russian Professor Popoff invented wireless telegraphy simultaneously with Marconi and the latter, I understand, freely acknowledges this.

In aeronautics Russia has been well to the fore. Sikorski designed and built in 1912 what I believe was the first aeroplane to carry a dozen or more persons.

WATER POWER LEGISLATION

The long-pending water power development bill received final action by Congress when the Senate approved the conference report by a vote of 45 to 21.

When the bill was sent to the President for signature it had to be referred to the Secretary of the Interior, the Secretary of Agriculture and the Secretary of War because it involved parts of bureaus and offices coming under their jurisdiction. The Secretary of the Interior recommended to the President that this bill be held up because of the effect which, it had been reported to him, would be had on the National parks. When the Secretary was apprised of the facts in the case however he withdrew his objections to the legislation, but it was then too late for the President to sign the bill because Congress adjourned that afternoon.

A subsequent ruling from the Attorney General's Office declared that under existing conditions the President could still sign the bill within ten days from the time it was received from Congress, and that the bill would become law by such action. This time limit expired on June 11th at midnight, and several days after this it was announced that the President had signed the bill within the time limit specified thus making it a law.

POLITICAL PARTY ENDORSES DEPARTMENT OF PUBLIC WORKS IN PLATFORM

One of the planks in the platform of the Republican Party at Chicago read as:

Reorganization of Federal Departments and Bureaus. "We advocate a thorough investigation of the present organization of the Federal departments and bureaus with a view to securing consolidation, a more businesslike distribution of functions, the elimination of duplication, delays and overlapping of work and the establishment of an up-to-date and efficient administrative organization".

This was initiated and brought about by the National Public Works Dept. Assn. It is understood in Washington that the Smoot-Reavis bill proposing a general reorganization of all departments along the lines suggested by the Engineers for the Department of Public Works carries the provision that the first department to be so reorganized will be the Department of the Interior and its conversion to a Department of Public Works.

IMPORTANT CONFERENCE ON HUMAN RELATIONS IN INDUSTRY

Under the Auspices of a Committee of Prominent Leaders of Industry Cooperating with the Y. M. C. A.

There will be held this year at Silver Bay, Lake George, New York, August 27th to 29th, a conference on "Human Relations in Industry." Over six hundred representatives of industry are expected to attend, including some of the most prominent industrial leaders. Among the speakers who have already accepted are Mr. Allen T. Burns, Americanization Study of the Carnegie Foundation for the Advancement of Teaching; Mr. F. J. Kingsbury, President, Bridgeport Brass Company; Mr. Clarence H. Howard, President, Commonwealth Steel Company; Mr. C. J. Hicks, Assistant to the President, Standard Oil Company; Mr. R. B. Wolf, Consulting Engineer; Mr. S. J. Carpenter, Lumber Manufacturer; Mr. L. P. Alford, Editor, Industrial Management; and Mr. Timothy Healy, International Brotherhood of Stationary Firemen.

A similar conference held at Silver Bay last year, attended by five hundred prominent industrial leaders and others, created a demand for a larger conference this year. The greatest problems of the day are industrial. The most important factor in industry is the human factor. Men dealing with the human factor want to get together, exchange experiences, and discuss these matters with experts in the field. The conference at Silver Bay affords the ideal opportunity. Members of the A. I. E. E. who would like to attend should reserve accommodations through Mr. Fred. H. Rindge, Jr., Secretary, Industrial Service Movement of International Y. M. C. A., 347 Madison Avenue, New York City.

FALL MEETING OF A. I. M. E.

The American Institute of Mining and Metallurgical Engineers will hold its fall meeting in the Lake Superior, Copper and Iron districts, August 20 to September 3, 1920. Houghton will be the first general assemblying place, and from there a trip will be made by special trains to Duluth, one train by way of Ishpeming, another by Vulcan. From Duluth the guests may either return to Chicago by special train, or go to Buffalo by steamship.

Technical sessions have been provided for at various stops, also social entertainments. Those who make the trip will have a chance to see many interesting developments in mining engineering, such as a new hoisting plant, from a depth of 12,500 feet, which will be in operation at the time of the visit in Houghton. Members are requested to make early reservations for themselves and their guests, as accomodations are limited.

ILLUMINATING ENGINEERING SOCIETY ELECTS OFFICERS

The election of the following officers of the Council of the Illuminating Engineering Society for the fiscal year 1920-1921, was confirmed by the Council on June 11th, 1920. These men were elected to fill the offices made vacant by expiration of terms: President: General George H. Harries; Vice-Presidents: H. F. Wallace, Dr. Geo. S. Crampton, J. J. Kirk; General Secretary: Clarence L. Law; Treasurer: L. B. Marks: Directors: Adolph Hertz, Walton Forstall, Frank S. Price.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

CLASSIFICATION AND COMPENSATION OF ENGINEERS

In reserving its efforts to advance the material as well as the professional interests of the members of the engineering profession, the Committee on Classification and Compensation of Engineers, of Engineering Council desires the benefit of the views of individual engineers as to the suitability of the scale of compensation and the employment policy suggested in their report which was published in the February 1920 issue of the JOURNAL of the Institute. Information of this sort will be of substantial assistance in enabling the Committee to complete its investigation and it is intended to make it available to any group of engineers for use in discussing these matters with those who have responsibility for fixing compensation. Members of the Institute and other interested engineers are urged to communicate any information which they may have or to express their views to Arthur S. Tuttle, Chairman, 1347 Municipal Building, New York.

EXTRACTS FROM REPORT OF NATIONAL SERVICE DEPARTMENT

June 17, 1920

Since the last meeting of Engineering Council many events of interest have taken place in connection with the work of the National Service Department and it is believed that the interval has been productive of more useful results to the engineering profession than in any similar period since the establishment of the Washington office. In many instances the efforts of the Department with respect to legislation, appointments, etc. have been apparently non-productive, yet this statement is true with respect to the work of every other organization in Washington, not excluding Congress itself. An impartial survey of the situation demonstrates that we have experienced a smaller percentage of failures than almost any other public body interested in National affairs. It is to be remembered that failure in a tangible instance does not mean lack of progress. In the matter of securing the appointment of engineers to engineering positions, for example, every time we fail we become stronger for the next attempt. Overlying all is the fact that we are still new in the field. Official confidence is something that is secured slowly, and the engineers cannot expect after decades of non-participation to jump into the arena and achieve success over night.

Requests for Assistance and Information. During the past seven weeks requests for assistance and information from the engineering profession have numbered 62.

Among the special services rendered and not included in this number are: (a) a full report on the status of compulsory military training, for the Colorado Society of Engineers; (b) efforts to secure the appointment of a representative from the American Society of Mechanical Engineers to the Council of the Petroleum Research Institute; (c) the effect of the proceedings of the Buenos Aires trade mark convention on copyrights in this country, for the American Society of Mechanical Engineers; (d) the accredited status of the so-called Swiss Economic Tours, for the American Society of Mechanical Engineers; (e) an investigation of the substitutes devised and used by Germany during the war period, at the request of the American Society of Mechanical Engineers. It is an interesting fact that the American Society of Mechanical Engineers makes more use of the Washington office of Engineering Council than do all of the other member societies combined.

Appointment of an Engineer to the International Joint Commission. Shortly after the death of Governor Glynn, a member of the International Joint Commission, Council's request for the appointment of an engineer in his place was presented at the White House, accompanied by a list of engineers who were regarded as qualified for service on that commission. This effort was supplemented by representations made to members of Congress who are supposed to be interested or influential in the matter, and also by several engineering organizations in the State of Minnesota, especially in advocacy of the appointment of Mr. Shenehon. Our last advice is that the President had received and taken note of the several recommendations and had determined upon the appointment, but we have so far been unable to ascertain the name of the appointee.

Appointment of Engineer to Interstate Commerce Commission. As the representatives on Council are probably aware our efforts to secure the appointment of an engineer to the Interstate Commerce Commission failed. The President appointed three representatives but the Senate refused to confirm the appointments and since the adjournment of congress these three men have been given recess appointments.

Advisory Board to Post Office Commission. Efforts to secure the appointment of one or more engineers on the Advisory Board attached to the Post Office Commission for the study of mail transportation systems in cities have apparently failed.

Advisory Council to the U. S. Board of Surveys and Maps. The Washington representative has completed his duties in connection with the organization of this council, and the future activities of Council will probably be guided by the necessities as they appear from time to time.

Convention Assistance. Among the time-consuming the laborious duties carried on by Mr. Oliphant of the Washington office are the work for the Joint Conference Committee in caring for the local arrangements of the organizing conference of engineering societies, which was held in Washington, and similar work for the Chairman of the Convention Committee of the American Institute of Electrical Engineers in connection with the forthcoming White Sulphur Springs convention.

Amendment to the War Minerals Relief Act. At the last meeting of Council your representative was authorized to proceed adversely to the legislation amending the present War Minerals Relief Act, and is glad to report that although the bill was slipped through the Senate, action in the House has apparently been blocked, and even the bill which passed the Senate contains errors which will make its reconsideration necessary by that body. As such reconsideration can be secured with difficulty, except by unanimous consent, and as unanimous consent is apparently impossible to secure, it is believed that this bill has been effectively killed for the present at any rate.

Taxation of Personal Service Corporations. It is believed that Council may render service to the entire profession by calling the attention of the engineering organizations to pending legislation on the taxation of personal service corporations. The bill is H. R. 14197 and has been favorably reported from the Committee on Ways and Means and is now on the

union calendar of the House of Representatives. "A personal service corporation, as defined in the revenue law of 1918, means a corporation whose income is derived from a profession or business (a) which consists principally of rendering personal service; (b) the earnings of which are to be ascribed primarily to the activities of the principal owners or stockholders; and (c) in which the employment of capital is not necessary or is only incidental * * * * * *."

Obviously, this includes engineering corporations, of which there are a large number in the United States, and the prosperity of which affects the professional welfare of all members of the profession whether in the employer or employee class.

The provisions of the act of 1918 taxed these corporations practically the same as partnerships, but the decision of the Supreme Court, while not specifically mentioning such corporations, has raised a question as to whether this portion of the act of 1918 is not invalid. The effort of the Committee on Ways and Means to pass legislation covering these doubtful points was inspired by a letter of the Secretary of the Treasury dated March 17, 1920 recommending amendatory legislation to make certain that the decision of the Supreme Court relative to stock dividends does not exempt from income and profits taxation personal service corporations and their stockholders. Time will not be taken here to analyse the facts and conditions and proposed legislation. It is recommended, however, that the matter be referred to an attorney-at-law for thorough analysis and that a small committee consisting of engineering stockholders in such corporations who are members of one or all of the constitutent societies of Engineering Council be requested to prepare a statement on the subject for circularization among the engineers of the country, and that when the proper time arrives steps be taken to present to Congress the opinions which are finally evolved by this committee. It is very clear that unless Congress is made aware of the peculiar conditions and circumstances that surround the conduct of professional engineering corporations the bill as finally enacted may contain provisions wantonly detrimental not only to the corporations themselves but to all engineers who directly or indirectly are affected by the progress or poverty of these corporations.

Nation Plans. The writer desires to invite Council's attention to a project which involves a long forward look—something which cannot be accomplished within a short time but which the writer believes to be worthy of a place on the constructive program of the engineers of the country. The subject is nation planning, the essential feature of which is the extension to national scope of the principles and ideals underlying what we know as city planning, that is, the efficient arrangement and direction of the public and private utilities of the Nation so that they will contribute to the maximum extent to the social, industrial and economic weal. The fact is becoming more and more apparent that the cities are after all merely the foci through which the economics of the Nation are made manifest, and city planning is but the first economic step in the improvement of our economic status.

This matter of nation plans has been visualized by Mr. Cyrus Kehr of Knoxville, Tenn., who has organized the so-called "Joint Board on Nation Planning," of which he is Chairman.

Mr. Kehr is a visionary man whose dreams tend to converge toward practicalities. He has completed the manuscript of a book on the subject of nation plans, which the writer has read with much interest. Of course the subject is too big for any one man and the great merit of Mr. Kehr's work lies in its ideals and generalities. He clearly describes a field full of logic and promise, while his discussion of details is valuable if for no other reason than to reveal the complexity of the subject and to show the need for many wise guiding hands. The whole subject is so attractive that it will, (if indeed it not already has,) stir the imagination of the chronic reformers who are constantly looking for new Elysian fields. If this movement is not steered wisely it will result in untold misfortune, disarrangement of values, disruption of credit and industrial chaos. The country is now in a condition to go to extremes on everything that is new so long as it is sufficiently revolutionary. For that reason, if for no other, it appears to the writer wise that this movement be guided by men of stability, while on the other hand it is believed that it contains so vast a field of merit that it is not only worth while but also highly desirable.

The matter is in large degree an engineering concern and it is thought appropriate for the consideration of Engineering Council. It is suggested that Engineering Council act for the present as a committee of the whole on this subject and that each member review the proposal between the present and the next meeting of Council, the idea being to take positive or negative action at the October meeting.

COMPARISON OF REPORT OF CONGRESSIONAL JOINT COMMISSION WITH REPORT OF COUNCIL COMMITTEE ON RECLASSIFICATION OF SALARIES

On March 12, 1920, the Congressional Joint Commission on Reclassification of Salaries presented its report to Congress. Ever since this report was made public, discussion concerning it has been rife, and naturally much misunderstanding about the recommendations regarding salary schedules and employment policies has gained currency. In an endeavor to clear up these misunderstandings and in order to present an analysis of the Commission's report, the Committee on Classification and Compensation of Engineers presents the accompanying table "Comparison of Report of the Congressional Joint Commission on Reclassification of Salaries with the December 1919 Report of Council's Committee."

The essential features of the Joint Commission's report are incorporated in the table which shows the salary range for the various grades of service as compared with that suggested by Engineering Council. The table also shows how the average salary as proposed by the Joint Commission, compares with the average salary received by employees in 16 engineering bureaus in civil establishments of the Federal Government on July 1, 1919.

There have been certain increases since that date, particularly in positions carried on lump sum appropriations. It is probable, therefore, that averages at the present time would be slightly higher than those shown in Column 14, particularly in the lower grades.

The research staff of the Commission made estimates of the average salaries in the different classes for the Engineering service which are somewhat different from the figures of Column 14. They are slightly higher in the lower grades and slightly lower in the higher grades. These differences are brought about as follows: The Commission's averages are for the Washington service only. The averages in Column 14 include both the Washington and the field services. The Commission's figures included salaries paid in civilian positions in the War and Navy Departments. The Navy Department schedule is considerably higher than that of the civil bureaus and therefore the Commission's averages would be somewhat higher on this account alone. Finally, the averages will vary according to the classification of positions. It is believed that the Commission classified positions more liberally than Engineering Council's Committee. The Commission probably included more positions in the higher grades than did Council's Committee, with the result that the averages for these grades are lower in the Commission's than in Council's calculations.

Since the Commission in any comparison of proposed with existing salary scales will use somewhat different data, it is evident that the averages will not be identical. There appears no doubt, however, that in the lower two grades the averages proposed are less than the averages now paid with the bonus, but how much less will depend upon what positions are classed within these grades and what date is taken for determining the averages.

In the Professional Group, the Joint Commission recommends the same educational and experience standards for grades 5, 4, and 3 as Engineering Council, but it recommends 4 years "in the direction or performance of important engineering works for grade 2, and 8 years for grade 1, against Engineering Council" recommendation of 3 years, and 5 years, respectively. The Joint Commission provides for a minimum increase in salary from $1800 for grade 5 to $4140 for grade 2; *i.e.*, $2340, or 130 per cent in a minimum of eight years. Engineering Council provides for a minimum increase for the same grades and number of years from $1620 to $5940; *i.e.*, $4320 or 267 per cent more than double the rate of increase recommended by the Joint Commission.

TABLE SHOWING COMPARISON OF CLASSIFICATION AND COMPENSATION OF ENGINEERS

As Suggested by Engineering Council Committee and by Congressional Joint Commission and of Average Salary per Annum as Suggested by Congressional Joint Commission and Present Average Salary of Employees in 16 Engineering Bureaus in Civil Establishments of the Federal Service

Grade	Engineering Council: Title	Educational Equivalent	Minimum Experience in Years	Annual Salary Range: Minimum	Maximum	Estimated Average
1	2	3	4	5	6	7
8	a. Junior Aid, Office b. Junior Aid, Field	High School	0	1080	1560	1240
7	a. Aid, Office b. Aid, Field	"	2	1680	2400	1920
6	a. Senior Aid, Office b. Senior Aid, Field	"	5	2520	3240	2760
5	Junior Assistant Engineer	Degree	0	1620	2580	1940
4	Assistant Engineer	"	2	2700	4140	3180
3	Senior Assistant Engineer	"	5, 1*	4320	5760	4800
2	Engineer	"	8, 3*	5940	....	....
1	Chief Engineer	"	12, 5*	8100	....	....

Grade	Congressional Joint Commission: Title	Educational Equivalent	Minimum Experience in Years	Annual Salary Range: Minimum	Maximum	Estimated Average	Present Average Yearly Salary (Note)	Average Per Cent Increase or Decrease (Note)
1	8	9	10	11	12	13	14	15
8	a. Copyist Draftsman b. Junior Engineering Aid	High School Common School	0	840	1260	980	1215	—19
7	a. Draftsman b. Aid	High School	2	1200	1800	1400	1533	— 9
6	No Corresponding Grade							
5	Junior Engineer	Degree	0	1800	2160	1920	1959	— 2
4	Assistant Engineer	"	2	2400	3000	2600	2402	+ 8
3	Associate Engineer	"	5, 1*	3240	3840	3440	3128	+10
2	Engineer	"	8, 4*	4140	5040	4440	3801	+17
1	a. Senior Engineer b. Commissioner, Director, Chief Engineer, Chief, Superintendent, etc.	"	12, 8* 8, —*	—	—	—	5867	—

NOTES

Columns 4 and 10. *Years in responsible charge of work.

Columns 7 and 13. Estimated average salary is the minimum plus ⅓ the difference between the minimum and the maximum. This relation was found to hold approximately for positions in the Federal Service and was assumed in the studies conducted in connection with the salary schedules of the Reclassification Commission.

Column 14. Present average yearly salary, including bonus, of employees in 16 bureaus in civil establishments of the Federal Government. The bonus is $240 for salaries of $2500 and under; for salaries above $2500, it is the amount, if any, necessary to make a total of $2740.

Column 15. Average percentage increase (+) or decrease(—) in pay per employee under schedule proposed by Congressional Joint Commission over present schedule if distribution of employees within each grade remains unchanged. The estimated increase in the salary roll which would be caused by putting the Commission's recommendations for all branches of the Civil Service into effect is, as estimated by the Commission, 8 to 10 per cent, probably 8.5 per cent.

AMERICAN ENGINEERING STANDARDS COMMITTEE

SPONSORS FOR SAFETY CODES SELECTED

Definite arrangements have been made for the formulation of a considerable number of safety codes under the auspices and rules of procedure of the American Engineering Standards Committee. The subjects of the codes for which arrangements have been completed, together with the organizations which have been designated by the Committee to act as sponsors, and who have accepted such responsibility are as follows:

Abrasive Wheels. The Grinding Wheel Manufacturers of the United States and Canada, and the International Association of Industrial Accident Boards and Commissions, joint sponsors.

Explosives. The Institute of Makers of Explosives, sponsor.

Foundries. The American Foundrymen's Association and the National Founders Association, joint sponsors.

Gas Safety Code. The U. S. Bureau of Standards and the American Gas Association, joint sponsors.

Head and Eye Protection. The U. S. Bureau of Standards, sponsor.

Paper and Pulp Mills. The National Safety Council, sponsor.

Power Presses. The National Safety Council, sponsor.

Pressure Vessels, Non-fired. The American Society of Mechanical Engineers.

Refrigeration, Mechanical. The American Society of Refrigerating Engineers, sponsor.

Woodworking Machinery. The International Association of Industrial Accident Boards and Commissions and the National Workmen's Compensation Service Bureau, joint sponsors.

A number of additional codes are under consideration. A large representative advisory committee of specialists, organized by the National Safety Council, the National Workmen's Compensation Service Bureau, and the Bureau of Standards, at the request of the Committee, to act as its advisor, is actively working on the question of what additional codes are most urgently required and what organizations are in the best position to undertake sponsorship for such codes.

AMERICAN SOCIETY FOR TESTING MATERIALS SUBMITS SPECIFICATIONS FOR APPROVAL AS AMERICAN STANDARDS

At a recent meeting of the American Engineering Standards Committee, five standard specifications were submitted by the American Society for Testing Materials for approval as "American Standards."

1. Standard Specifications for Drain Pipes
2. Standard Test for Toughness of Rock
3. Standard Test for Penetration of Bituminous Materials
4. Standard Method for Distillation of Bituminous Materials suitable for Road Treatment
5. Standard Method for Sampling Coal

All of these specifications are included in the *Proceedings* of the American Society for Testing Materials, or copies may be obtained from the office of the American Engineering Standards Committee at New York. These specifications were referred to a special sub-committee to make recommendations to the American Engineering Standards Committee for final action.

STANDARDIZATION OF BALL BEARINGS

At the request of the Swiss Standards Association, Baden, Switzerland, for cooperation in the work of standardization of ball bearings, the American Engineering Standards Committee requested the American Society of Mechanical Engineers and the Society of Automotive Engineers to act as Joint Sponsors for the project. These societies have accepted the responsibility and are now organizing a Sectional Committee for the work. The Sectional Committee will be thoroughly representative of all the interests involved and is the body which will be responsible for the detailed formulation of the standards.

FOREIGN STANDARDIZING BODIES VISITED BY SECRETARY OF THE AMERICAN ENGINEERING STANDARDS COMMITTEE

The American delegates who attended the meetings of the Advisory Technical Committees of the International Electrotechnical Commission, at Brussels, March 27th to April 1st, were accompanied by P. G. Agnew, Secretary of the American Engineering Standards Committee, who later visited the national standardizing bodies in Belgium, England, France and Holland.

The Association Belge de Standardisation was organized by the Central Industrial Committee of Belgium. While only recently organized, the Association is actively at work and has already carried out several important standardization projects.

The French Commission Permanente de Standardisation differs from other national standardizing bodies in that it is strictly an official organization, and supported wholly by government funds. It is a part of the Ministry of Commerce and Industry. The standards already adopted include the specifications for cement, tile, brick, also standards for electrical machinery, steel sections, and various elements of machine tools, such for example as tool rests, lathe carriages, keys, and keyways.

Most American engineers are more or less familiar with the British Engineering Standards Association and its work. It is the oldest and largest of the national organizations, having been founded in 1901 as the British Engineering Standards Committee. The work of the Association is playing a most important role in British industry. The standards now in effect cover an extensive range of engineering subjects.

The Main Committee for Standardization in the Netherlands was organized in 1916, by the Society for the Encouragement of Industry and the Royal Institute of Engineers. As in the case of Belgium, the relatively small size of the country, and the industrial and commercial position necessarily affect their standardization work. The form of publication is unique. Standards are issued as single sheets, perforated for binding in loose-leaf folders. The essential information is given in compact form, any necessary explanatory notes being given on the back of the sheet. The general style is that of a working drawing, and the idea is that they shall be issued directly to the draughtsman in the plant. The price is 15 Dutch cents ($0.06) per sheet. Their work is proceeding very actively. New sheets are being issued at the rate of about one per week. There are 16 on the staff of the central office.

The American Engineering Standards Committee is already in active cooperation with some of the other international bodies, the most important project being that of steel sections (with the British). There is an almost unlimited field for such work, and Dr. Agnew reports that he found a most cordial attitude and desire for cooperation on the part of all of the organizations which he visited.

There are similar national standardizing bodies in Canada, Germany, Sweden and Switzerland, while one is in process of organization in Italy.

NEW BODIES REPRESENTED

Five additional bodies have been admitted to representation on the Main Committee of the American Engineering Standards Committee. They are:

Electrical Manufacturers Council (Electric Power Club, Associated Manufacturers of Electrical Supplies, Electrical Manufacturers Club)

Fire Protection Group (National Fire Protection Association, National Board of Fire Underwriters, Associated Factory Mutual Fire Insurance Companies, Underwriters Laboratories)

National Electric Light Association

National Safety Council

Society of Automotive Engineers

These, with the five engineering societies who founded the Committee, (American Institute of Electrical Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Civil Engineers, American Society of Mechanical Engineers, American Society for Testing Materials), and the three government departments, added later, (Commerce, Navy, and War), make a total of thirteen organizations having representation on the Main Committee.

The Constitution of the A. E. S. C. provides for representation of "groups of organizations." It is the policy of the Committee to encourage representation by groups in such a manner that a group shall represent substantially the entire field of a particular industry in order that it may "be of national scope." In the opinion of the Committee the group plan makes both for efficiency in standardization work and for effectiveness of representation. The groups are autonomous, such matters as the apportionment of representatives and the allotment of fees among the constituent bodies resting wholly with the group.

Two of the new bodies have already designated their representatives as follows:

Electrical Manufacturers Council: LeRoy Clark, A. H. Moore, C. E. Skinner.

National Safety Council: C. P. Tolman, Chairman. Manufacturing Committee; Albert W. Whitney, General Manager, National Workmen's Compensation Service Bureau; Sidney J. Williams, Secretary and Chief Engineer.

NATIONAL RESEARCH COUNCIL

The National Research Council has elected the following officers for the year beginning July 1, 1920: Chairman, H. A. Bumstead, professor of physics and director of the Sloane physical laboratory, Yale University; First Vice-Chairman, C. D. Walcott, president of the National Academy of Sciences and Secretary of the Smithsonian Institution; Second Vice-Chairman, Gano Dunn, president of the J. G. White Engineering Corporation, New York; Third Vice-Chairman, R. A. Millikan, professor of physics, University of Chicago; permanent secretary, Vernon Kellogg, professor of biology, Stanford University; Treasurer, F. L. Ransome, treasurer of the National Academy of Sciences.

The Council was organized in 1916 under the auspices of the National Academy of Sciences to mobilize the scientific resources of America for work on war problems, and reorganized in 1918 by an executive order of the President on a permanent peace-time basis. Although cooperating with various government scientific bureaus it is not controlled or supported by the government. It has recently received an endowment of $5,000,000 from the Carnegie Corporation, part of which is to be expended for the erection of a suitable building in Washington for the joint use of the Council and the National Academy of Sciences. Other gifts have been made to it for the carrying out of specific scientific researches under its direction.

ANNUAL MEETING OF JOSEPH A. HOLMES SAFETY ASSOCIATION

The annual meeting of the council of the Joseph A. Holmes Association was held on March 5, 1920, at Washington, D. C.

This association was established to perpetuate the memory of Dr. Holmes, the creator and first Director of the Bureau of Mines, whose activities led to the inauguration of a nation wide movement for the conservation of life and health among the mining and metallurgical workmen and to the introduction of greater safety in these industries. Diplomas and medals of honor are awarded to persons in these industries for deeds of heroism in rescue work and to persons who may devise or put in use appliances for greater safety.

After presentation of various reports and other routine business a discussion was entered into on the necessity for obtaining much larger funds to carry on the work of the association. It was agreed that among others the various miners' unions would undoubtedly prove valuable sources of revenue if the benefits of the Association's work were properly placed before them. Big mining men and operating companies were also suggested as a fruitful source of funds.

The Committee on Awards, Diplomas, and Medals submitted a report in which it was shown that 16 awards had been made during 1919, the delivery of the diplomas and medals to take place at various public functions. In making the awards for 1920 the records of the Bureau of Mines and the reports of State Mine Inspectors have been carefully canvassed to locate deserving persons. Seven are recommended and their names with a brief statement of circumstances of the acts performed are included. All awards to date are for a very high order of heroism involved in rescue work.

The Institute is cooperating in this meritorious work and is represented in the Association by John H. Finney, Washington, D. C.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities, is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Arthur J. Hall, 624 East End Ave., Pittsburgh Pa.

2.—Lincoln Nissley, 1213 Pioneer Bldg., St. Paul, Minn.

3.—Cyril H. Light, Office of Inspector of Engineering Material, U. S. N., 938 Edison Building, Chicago, Ill.

PERSONAL

Carl A. Baer, of Carl A. Baer & Co., Engineers, Land Title Building, Philadelphia, announces that the firm's business will now be conducted under the name of Baer, Cooke & Company, Engineers, Land Title Building.

W. Frank Sutherland, formerly editor of Power House, has severed his connection with the MacLean Publishing Company, Toronto and has accepted a position on the engineering staff of the Deloro Smelting and Refining Company, Deloro, Ont.

E. K. Bibb has resigned from the Westinghouse Electric & Mfg. Company to accept the position of Assistant Electrical Engineer of the Jeffery-Dewitt Insulator Company. Mr. Bibb will be in charge of the factory testing and inspection for this company.

John D. Ball has resigned the Deanship of the School of Engineering of Milwaukee and has accepted a position as manager of the Planning Department for Ed. Schuster & Company of Milwaukee. Mr. Ball is retaining his affiliations with the School as vice president for the present.

Edward J. Cheney, secretary of the Standards Committee of the Institute, formerly connected with the General Electric Company and recently Chief of the Division of Light, Heat and Power of the Public Service Commission, Second District, Albany, N. Y., opened an office on June 1 at 61 Broadway, New York, for a general engineering and consulting practise, with particular attention to public utility problems.

L. Lustig, formerly with the G. & W. Electric Specialty Co., Chicago, and with the Switchboard Engineering Departments of the Westinghouse Electric & Mfg. Co., East Pittsburgh, and the General Electric Co., Schenectady, has been appointed

during his visit to his native country as engineer in charge of the Switchboard Engineering Department of the Křižik-Chaudoir Electric Mfg. Co., Karlin-Prague, Czechoslovakia

---

L. Earl Deane is leaving the American Enameled Magnet Wire Co., where he has served for more than six years in the capacity of traveling engineer and salesman, and will take up work under the Board of Foreign Missions of the Presbyterian Church. His assignment is to their work in French Cameroun, West Africa. About six months will be spent in France for language work after which he will proceed directly to West Africa.

H. L. Dawson, manager of the Chicago Office of the Cutler-Hammer Mfg. Co., which handles the business of nineteen states with sub-offices in Cincinnati and Detroit, has been removed from the Peoples Gas Bldg. to the company's own building on the new Michigan Boulevard link (323 No. Michigan Ave.). This new building makes available considerable extra storage space for the company, becoming necessary with their growth of business.

OBITUARY

Oliver B. Hodgson, lately connected with the Stone Franklin Company in the capacity of electrical engineer, died in New York on February 8, 1920, after a lingering illness. Mr. Hodgson was born in New York on November 20, 1887. He was graduated from Pratt Institute, Brooklyn, in 1908, and the following year entered the employ of the New York Central Railroad, specializing later in axle lighting apparatus. He left the New York Central in 1917 to become electrical engineer with the Stone Franklin Company, which position he held until September, 1919, when he resigned on account of poor health. Mr Hodgson joined the A. I. E. E. as Associate in 1910.

James R. Nelson, Superintendent of Power House, San Joaquin Light and Power Co., Springville, Cal., died March 29, 1920, following an operation. Mr. Nelson was born in Kansas in 1885. He went to California in 1910 and entered the employment of the San Joaquin Light and Power Corporation of Bakersfield as Superintendent of the Kern River Power House, and held that position until 1915 when he was transferred to Springville, Cal., where he was Superintendent of the Tule River Power House, remaining there until his death. He was an Associate of the A. I. E. E., and had joined also the N. E. L. A.

Charles Blizard, an Associate of the Institute since 1894, died on June 12, 1920, after a prolonged illness. Mr. Blizard had been in the electrical industry for about thirty years, first with the Franklin Accumulator Company, and then with the Electric Storage Battery Company, which he joined in 1893 as manager of the New York office. Later he became manager of sales for the same company, with headquarters in Philadelphia, and then third vice-president in charge of sales, holding this position until his death. He had also been one of the governors of the Associated Manufacturers of Electrical Supplies since its beginning and was chairman of the finance committee of that association for a number of years.

Edmund Gybbon Spilsbury, mining and metallurgical engineer of international reputation, died suddenly of heart failure May 28, 1920, in the New York Eye and Ear Infirmary, where the operation for cataract had been successfully performed upon his eyes a few days previous. He was President fo the American Institute of Mining and Metallurgical Engineers in 1896 and of the Engineers' Club of New York in 1916 and 1917. He was also a member of the American Society of Civil Engineers, the American Society of Mechanical Engineers, The Institution of Mining and Metallurgy of Great Britain, the Mining and Metallurgical Society of America, the American Electrochemical Society, and of the Rocky Mountain Club of New York. As the representative of one or another of the national engineering societies, he was a Trustee of United Engineering Society from 1916 until his death; a member of Engineering Societies Library Board from its organization in 1913 until 1920, being its Chairman from 1918 to January, 1920; and a member of the Engineering Foundation Board from 1916 until his death. He was also a member of the Division of Engineering of the National Research Council, of Washington and New York. In all these societies and boards, he was an active, useful member, serving on numerous committees and contributing freely of his time and ability.

Born in London, England, in 1845, he attended school in Liege, Belgium, whither he went at an early age. His technical education was gained at the University of Louvain, Belgium; he was graduated in 1862. After leaving the University, he had a practical course at Clausthal, Germany. He came to the United States in 1870. His practise as a consulting mining engineer and metallurgist took him into many parts of Europe, Africa, the United States, Mexico and South America. During the winter and early spring of 1920, he spent a number of weeks in Brazil on a mining project for clients in the United States and had returned to New York only a few weeks before his decease.

In 1864 he entered service of the Eschweiler Zinc Company, Stolberg, one of the largest miners and smelters of lead and zinc in the world, as Assistant Engineer; 1865 took charge of that company's mines and works on the Island of Sardinia; from Sardinia he went to the Atlas mountains, in Morocco. In 1867 he entered the service of McClean and Stilman of London, and had charge of the construction of the iron gates for the Surrey Commercial Docks; in 1868 he was designing engineer with J. Casper Harkort and had charge of most of the detail work of the Keulenberg Bridge in Holland and the Danube Bridge in Vienna, also the Rhine Bridge at Dusseldorf. In 1870 he was again with the Eschweiler Corphalic Company as Chief Engineer. In 1870 he was sent by the Austro-Belgian Metallurgical Company to investigate the resources of the United States in lead and zinc. After spending two years in this work, he resigned in order to practise in the United States, where he was the first to introduce the Harz system of ore-dressing for the zinc ores of Pennsylvania and New Jersey. During this period he was engaged in explorations also on the northern shore of Lake Superior and in Colorado, Montana, Utah and California. From 1873 to 1875 he was engaged as General Manager of the Bamford (Pa.) Smelting Works; in 1879 he designed and built the Lynchburg Blast Furnace and Iron Works; he was also Consulting Engineer for the Coleraine Coal and Iron Company, of Philadelphia. In 1883, he became General Manager of the Haile Gold Mine in South Carolina, and in 1887 engaged with Cooper, Hewitt and Company, of New York, and was Managing Director of the Trenton Iron Company, Trenton, New Jersey, from 1888 to 1897. While Manager of these works, he introduced as specialities of their business the Elliot locked wire rope and the Bleichert system of aerial tramways.

In 1893 he presided over the sessions of the Mining Division of the International Engineering Congress, of the World's Fair at Chicago.

He was the author of a number of important technical papers. In a lighter vein he also wrote entertainingly. To the Mining and Scientific Press in 1915, he contributed "Technical Reminiscences." This narrative recalls early interesting experiences and the notable progress in mining engineering during his half-century of active practise.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

INSTRUCTORS: All engineers willing to consider teaching positions are invited to register with Engineering Societies Employment Bureau. The Bureau has been called upon to fill more positions, varying in grade from laboratory assistant to heads of department, in various engineering and technical schools of this country, than it has been able to do from among the men now registered. Blanks for purpose of registration and information regarding the Bureau may be had by addressing W. V. Brown, Manager, 29 West 39th Street.

GRADUATE MECHANICAL AND ELECTRICAL ENGINEER, experience in car shop work. Competent to keep in first class condition of maintenance sub-surface-contact, electric, street railway cars, and to develop a repair shop for that work, selecting and placing the proper tools and take charge of such operations when effected. Location New York City. Z-1211.

INSTRUCTOR for technical school in electrical laboratory and class room work. Duties will include responsibility for an elementary electrical course, and assistance in a more advanced course. Must be engineering school graduate with few years practical experience. Previous teaching experience desirable. Apply by letter stating age, education and experience and enclose recent photograph if available. Location Brooklyn, New York. Z-1214.

ENGINEER for research and investigation on cable insulations. Must be able to conduct investigation on own initiative and report progress to company. Location Hastings, N. Y. Z-1272.

ELECTRICAL OR MECHANICAL ENGINEERS, technically trained, with selling experience on electrical or power plant installations to go to Columbia or Venezuela. Prefer men who have been through the General Electric Company's test. Age between 25 and 35. Z-1275.

INSTRUCTOR IN ELECTRICAL ENGINEERING. Duties beginning September 1st, in New England Engineering College, mainly instruction in electrical engineering Laboratory. Graduate of one or two years engineering experience desired. Z-1284.

INSTRUCTOR in Electric department school. Location Connecticut. Z-1331.

ELECTRICAL ENGINEER for research work on high-frequency current and particularly its application to plant life (electroculture). Must have thorough technical education and have had considerable experience in conducting research and in the practical application of the results therefrom. A knowledge of either chemistry, and allied subjects, or botany or of both, while not essential, is highly desirable. Although it involves his being absent from the United States for rather long periods at a time, this is an excellent opportunity for the man who can carry on the work, develop its practical application to industrial problems and later direct the research of others along similar lines. Z-1337.

ELECTRICAL ENGINEER to translate from French into English. German also desirable but not essential. Location New York State. Z-1352.

SUPERINTENDENT OF MINING property in Chile Technical graduate, preferably in Electrical or Mechanical. Executive and operating experience in electric railroading, steam turbine power plant, and open pit mining desirable. Only experienced men wanted. Knowledge of Spanish desirable, but not necessary. Good opporunity for right man. Give age, married or single, education, technical training technical and executive experience, salary expected, references and when available. Location Chile. Z-1355.

INSTRUCTOR IN ELECTRICAL ENGINEERING for 11 months work commencing September 1st. Candidates should be graduates with an Electrical Engineering degree and should have had some experience either in practical work or in teaching. Location Ohio. Z-1359.

GRADUATE MECHANICAL ENGINEER, with electrical and shop experience for large textile mill. The position will be that of Mechanical Superintendent and will embrace direct supervision of machine, carpenter, pipe, blacksmith, tinsmith shops, etc. The work will require a man with executive qualifications and a large amount of tact. State training, age, references, salary and other details necessary for reaching quick decision. Location Rhode Island. Z-1389.

GRADUATE ELECTRICAL ENGINEERS under thirty years of age, for investigating problems of inductive interference between power and communication circuits and for designing remedial measures in the Rocky Mountain region. Positions are open for men to take the lead in this work and for assistants. Preference given to those having experience in radio, telegraph and telephone work. Apply stating salary required. Z-1410.

SUPERINTENDENT familiar with small generator construction for department employing about 60 men engaged in manufacturing engines, switchboards, and generators for farm lighting plants. One man as general factory superintendent, who has a production knowledge in the items mentioned and understands the importance of keeping in contact with the working men in actual production operations. Location Wisconsin. Z-1411.

WORKING FOREMAN who knows how to wind armatures and has a general knowledge of small generator manufacture of about 1 kw. capacity. Location Wisconsin. Z-1412.

INSTRUCTOR IN MATHEMATICAL DEPARTMENT, young man. Principal work will be to give an elementary course in calculus to engineering students. Location New York State. Z-1439.

EXAMINATION TO FILL VACANCIES IN THE COMMISSIONED GRADE OF ASSISTANT CIVIL ENGINEER, CORPS OF CIVIL ENGINEERS, U. S. NAVY

Applications are being received at the Bureau of Yards and Docks, Navy Department, Washington, D. C., to fill 30 vacancies, more or less, in the commissioned grade of Assistant Civil Engineer, U. S. Navy, with the rank of Lieutenant (junior grade) The pay and allowances at entrance are approximately $3,200 per annum, with increases up to $9,600, depending upon length of service and promotions.

The candidate must be an American citizen, between the ages of 21 and 34 years on August 1, 1920; must have received a degree in engineering from a college or university of recognized standing; must have had not less than 12 months' practical, professional experience since graduation, and must be of good moral character and repute.

The preliminary examination to determine general fitness will be based on papers submitted by the candidates, reaching the Board on or before August 23, 1920, covering college record testimonials, references, and professional experience. The candidate is not required to report in person for the preliminary examination. Physical examination by a Board of Medical Examiners will be made of those candidates who qualify in the preliminary examination.

Those who qualify in the preliminary and physical examinations will take the final oral and written examinations to be held in Washington, D. C., as soon as possible after the preliminary examination papers have been passed on by the Board.

Officers of the Corps of Civil Engineers are detailed principally to the various navy yards and naval stations to supervise the work under the Bureau of Yards and Docks, Navy Department, Washington, D. C., consisting of the design and construction of all the public works of the naval establishment on shore as

well as the maintenance and repair of existing structures. The work is exceptionally varied and offers an attractive field for able and ambitious young engineers. Z-1485.

C. W. PARKS, *Chief of Bureau.*

PRODUCTION ENGINEER, technical graduate, electrical or mechanical, between thirty and forty years of age, thoroughly competent to plan, tool-up, organize and maintain efficient production on a large scale of a fractional motor, in the small motor department of a large corporation in New England; a man of strong character and personality backed by record of achievement. Z-1450.

OPERATING & CONSTRUCTING ENGINEERS with operating company in Southwest service, population of about one hundred and eighty thousand, previous experience in construction and operation of distribution systems, substations and power plants, desirable technical training essential, in applying give age, married or single, education, technical training experience, salary expected, references and when available. Z-1484.

DRAFTSMEN (2) good advancement, must be acquainted with high-tension electrical design. Capable of doing own designing preferred. Location New Jersey. Z-1489.

EXPERIENCED ELECTRICAL SUBSTATION OPERATORS having a technical training and capable of promotion. State experience, education and salary desired. Location Illinois. Z-1490.

TRANSFORMER DESIGNER, young, capable and up to date to fill position in Sydney. Good possibilities. Expenses paid to Sydney and if the man is not satisfactory, his expenses will be paid back. Location Australia. Z-1492.

ASSISTANT PROFESSOR and Instructor in Electrical Engineering. Location Kansas. Z-1503.

ENGINEERS for research and development work on radio apparatus. Applicants should have an electrical engineering degree or its full equivalent in training and experience and must have had substantial experience in radio engineering. Apply by letter only to Engineering Manager, International Radio Telegraph Company, 326 Bway. New York City, stating age, education, radio experiences, references and salary desired. Z-1504.

INDUSTRIAL PHYSICIST OR ENGINEER interested in research on electrical control problems. Location, Middle West. Salary, according to training and experience. Z-1525.

YOUNG MAN, graduate engineer, to teach physics. Location New Jersey. Z-1506.

MEN AVAILABLE

GRADUATE ELECTRICAL ENGINEER, 25, two years experience in operating before graduation. One year Sales Engineer in Mechanical and Electrical Work. Desire general electrical work with some sales opportunity. Prefer position of immediate or eventual location in Orient or South America. E-2224.

GRADUATE ELECTRICAL ENGINEER desires business or engineering position with growing concern near Boston, 6 years office and field experience in power plant and distribution design including some mechanical and civil engineering experience. B. S. Tufts College. Familiar with contract work, estimating, and power equipment. E-2225.

YOUNG MAN, age 28, single; partial technical training. Five years electrical experience, actual construction, engineering, and merchandise jobbing. Desire position with prospects for advancement to an executive position. Any Location. Available immediately. E-2226

SALES ENGINEER, with fourteen years experience large electric manufacturing company including ten years on apparatus sales and executive work. Desire position as representative of reliable company in Ontario, or executive position of business nature requiring a knowledge of engineering. E-2227.

TECHNICAL GRADUATE; in charge of electrical engineering department of large designing and contracting company. Familiar apparatus and material of electrical and allied industry, through specifying, selecting and recommending. Speak Scandinavian and German. Will consider exporting firms. E-2228.

PRACTICAL ELECTRICAL MAN, on any electrical field work. Age 21, single, 5 years practical experience, 3 years technical training. Salary $1500, exclusive of room and board expenses. Location desired Wisconsin. E-2229.

GRADUATE ELECTRICAL ENGINEER of 10 years standing from an Eastern Institution. 34, married, speak French. Experienced supervision and direction of tests, instrument work, line construction cable work, electrolysis mitigation. At present with power department of large street railway company in New York as Electrical Assistant. Salary $3400. E-2230..

ENGINEER, SUPERVISING or operating chief; position of responsibility in charge of power plants or plant and mechanical and electrical industrial equipment especially where proportionately large amount of steam and power is used in manufacturing; 20 years experience. Married, Location immaterial. Salary commensurate with position. Immediately available. E-2231.

ELECTRO MECHANICAL ENGINEER, Cornell; 2 years general electric test; 2 years inspection work at large shipbuilding plant. Desire position with good opportunity for advancement. New York City preferred. Available short notice. Salary $2400. E-2232.

ENGINEER AND MANAGER; technical graduate, eight years factory construction and field installation of electrical machinery and operation of power plants and transmission systems, two years and at present district manager of gas, water and electric properties of a large holding company. Middle West location desired; minimum salary $3300. E-2233.

POWER ENGINEER, 15 years experience. Generation, distribution and Construction in United States; Canada and England. Industrial Construction and Appraisal. Good knowledge of chemistry. Alexander Hamilton Institute Business Training. Desires responsible position with large industrial or public utility concern. Prefer New England but would consider British connection. E-2234.

ELECTRICAL ENGINEER; desires location Pacific Coast. Age 34. A. B. and E. E. degrees. Ten years with large engineering and construction company responsible for electrical estimates, designs and purchases in connection with power stations, industrial plants and various power and lighting applications. Salary $4500. E-2235.

TECHNICAL GRADUATE, 36, 5 years electric railway experience, prefer heavy traction electric railway work, but will consider any engineering work pertaining to electric traction. E-2236.

ELECTRICAL ENGINEERING TEACHER, 12 years experience at institutions of recognized standing. Position leading to head of department preferred. Broad experience in commercial engineering work. Age 35 married. Minimum $3500. E-2237.

PROFESSOR OF ELECTRICAL ENGINEERING, now engaged on electrical research and development. Desires to return to teaching in University where Engineering research can be organized. Over ten years experience in large University. During war (Major) in charge of extensive work. Minimum $4000. E-2238.

CAPABLE EXECUTIVE, Graduate Electrical Engineer, Naval Engineering Officer during war, now with government in position of responsibility in electric propulsion work, desires to connect with private manufacturing concern. Considerable efficiency and organization ability, with experience obtained from contact with many large manufacturing companies during war period. E-2239.

PROFESSOR OF ELECTRICAL ENGINEERING, broad education; Member of A. I. E. E. Thirteen years practical and teaching experience in mechanical and electrical engineering. Minimum salary $3500. Also desire temporary connection for summer months. E-2240.

ELECTRICAL ENGINEER; graduate 1917; business training, two years operation, maintenance, power plants, refrigerating machinery; lightning arrester installations. Lieutenant, Signal Corps. Telephone experience; assistant to consulting engineer, one year. Will accept responsible teaching position in engineering college, manufacturers educational department or position as electrical engineer with railway, power, or manufacturing company. E-2241.

ELECTRICAL ENGINEER, technical graduate, 2 years G. E. Test, 1½ years Construction Foreman, 1 year Second Lieutenant, 1 year laboratory instructor University. Desires employment in power work as factory Electrical Engineer. Power superintendent, or Assistant purchasing Agent. E-2242.

ASSISTANT CONSTRUCTION ENGINEER, ELECTRICAL. Technical graduate with six years of railroad, telephone and power experience. Age 27. Salary $225-250 per month. E-2243

YOUNG MAN, 24, 5 years experience electrical engineer, duties electric hoists, power and substation, radio apparatus engineering correspondent with manufacturing concern. At present assisting vice-president of public utility in valuation etc. Self educated. Initial salary $200 per month. E-2244.

ELECTRICAL ENGINEER, (B. E. 1919) desires connection Baltimore district. Experience includes investigations and re-

ports on power and transmission problems, industrial layouts, industrial sales engineering and a variety of industrial engineering problems. Position with good future desired. E-2245.

MECHANICAL AND ELECTRICAL ENGINEER 15 years experience in the design, erection and operation of power plants steam and electrically driven manufacturing machinery. Qualified as executive to handle many men in all departments. Good experience in the combustion of bituminous and anthracite coal. Operation and maintenance of extensive heavy equipment are my specialties. Salary $7500 per year. E-2246.

ELECTRICAL RAILROAD INSPECTOR with technical education. Qualified in both Electrical and Mechanical features of light and heavy traction equipment. Is experienced in D. C. and high voltage A. C. Railroading. Position in or around New York City, desired. At present employed on large railroad with A. C. trunk line electrification. E-2247.

GRADUATE ELECTRICAL ENGINEER (1909) married, age 31 desires position of greater responsibility in consulting and engineering. Has had factory and office experience, also erection repair and executive experience with large industrial corporation. Capable of handling construction erection and operation work. Salary $3000. Available at once. E-2248.

ELECTRICAL ENGINEER, 32, university graduate desires engineering position. 9 years experience in construction, design and distribution of power plants, substations, transmission lines, etc. E-2249.

TECHNICAL GRADUATE, age 42, married, Associate A. I. E. E. Three years Westinghouse test, motors and generators, year and one half erecting engineer. Eight years superintendent municipal light, power and water works. At present holding such position. Desires change offering responsible position with broader opportunities. Available at short notice. E-2250.

ELECTRICAL ENGINEERING GRADUATE with twelve years practical experience in design, construction and maintenance of steam and industrial power plants and substations in the west. Age 34, single. Desires position with manufacturing concern in or near New York. Salary $4000. E-2251.

GRADUATE ELECTRICAL ENGINEER with ten years experience in design, construction, maintenance and operation of hydroelectric and commercial electrical equipment wishes to connect with some large concern which appreciates initiative, executive and technical ability, proven dependability and personality. At present holding responsible position and in excellent standing. Reason for change purely personal. Married. Age 30. Salary about $4000 depending on location. E-2252.

EXECUTIVE MECHANICAL AND ELECTRICAL ENGINEER (Graduate 1911) of broad electrical and mechanical experience in testing of machinery, production and cost accounting. Thoroughly familiar with modern production methods, accounting, the installation and operation of scientific management. Ex-army officer. Age 32, unmarried. Would consider a sales proposition. Salary of secondary consideration to opportunity. E-2253.

ASSOCIATE MEMBER OF A. I. E. E. and certified member of several other national engineering societies who has had engineering and scientific college training now supplemented by several years practical experience with both Electrical Utility and Manufacturing Companies of East along lines of designing, experimental, research and test engineering desires a position as Electrical Engineer or similar supervisory position where a steady, ambitious person of good ability, character and habits, with wife and child can locate in permanent position. Fair living salary desired at start:—commensurate with duties and location but salary is of secondary importance to other conditions as permanency, living conditions, advancement and treatment accorded. E-2254.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (MAY 1-31 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

AIRMAN'S INTERNATIONAL DICTIONARY.

Including the most important technical terms of aircraft construction, English—French—Italian—German. Edited by Mario Mele Dander. Lond., Charles Griffin & Co., Ltd. (1919). 227 pp., 6 x 4 in., cloth, 6 shillings. (Gift of J. B. Lippincott Co.)

The terms in this dictionary are classified under systematic headings, so that those relating to a particular part of the airplane are brought together, and an alphabetic index is provided.

ASBESTOS AND THE ASBESTOS INDUSTRY AND OTHER FIREPROOF MATERIALS.

By A. Leonard Summers. Lond. & N. Y., Sir Isaac Pitman & Sons, Ltd., n. d. 107 pp., illus., plates, 7 x 5 in., cloth, 2s 6d.

This little book gives a non-technical account of asbestos, its sources, varieties and uses, that is intended for users of this material and for general readers, rather than for those in search of detailed information.

AUTOMOBILE CONSTRUCTION AND REPAIR.

With Questions and Answers. By Morris A. Hall. Chicago American Technical Society. 1920. 711 pp., illus., 8 x 6 in., flexible cloth, $3.50.

In this book the various parts of the automobile are described in detail, and explicit instructions for their adjustment and repair are given. The volume is intended for owners, chauffeurs and repairmen.

CEMENT.

By Bertram Blount, assisted by William H. Woodcock and Henry J. Gillett. Lond. & N. Y., Longmans, Green & Co., 1920. 284 pp., illus., plates, tables, 9 x 6 in., cloth, $6.00.

This monograph, like its companion volumes, is intended to give a connected, balanced account of the cement industry, in the light of our scientific knowledge of the principles underlying it. Processes are explained, so far as they are necessary to elucidate principles, but no attempt is made to present minute technical details.

COAL MEN OF AMERICA.

Arthur M. Hull, Editor-in-Chief, Sydney A. Hale, Associate Editor. Chic., The Retail Coalman, 1918. 506 pp., portraits, 12 x 9 in., cloth, $10.

A brief historical and descriptive account of the coal trade in each state is given, followed by alphabetical lists of those engaged in it. The business connections of these men are noted and many portraits are included. The coal trade, not coal mining, is the industry under consideration.

CREATIVE CHEMISTRY.

Descriptive of Recent Achievements in the Chemical Industries. By Edwin E. Slosson. N. Y., The Century Co., 1920. 311 pp., illus., chart, plates, 8 x 6 in., cloth, $2.50.

In this work, Dr. Slosson gives a readable account of some of the great results of modern chemical activity, as well as some of the big problems which engage attention today. The book is intended for general readers and as supplementary reading for college students.

DYKE'S AUTOMOBILE AND GASOLINE ENGINE ENCYCLOPEDIA.

Treating on the Construction, Operation and Repairing of Automobiles and Gasoline Engines—also Trucks, Tractors, Airplanes and Motorcycles.

By A. L. Dyke. Twelfth edition. St. Louis, A. L. Dyke. 940 pp., illus., charts, 10 x 7 in., cloth, $6.

This well-known book has undergone its annual revision and has also been enlarged by the addition of material on motor trucks, tractors, motorcycles and airplanes. With its wealth of illustrations and its clear, practical information on all subjects connected with automobile operation and repair, it is well named an encyclopedia of the subject.

A FEW SECRETS OF THE METALLURGIST SIMPLY TOLD.

By Gerald W. Hinkley. First edition. Atlas Crucible Steel Co., Dunkirk, N. Y. 99 pp., 7 x 5 in., cloth, $1.00.

The question discussed by the author is "Why does steel harden?" This he answers by a brief non-technical explanation of the allotropic theory of iron and steel, suited to those without metallurgical training. About half of the book is devoted to alloy steels.

FORGE-PRACTISE AND HEAT TREATMENT OF STEEL.

By John Lord Bacon. Third edition, revised & enlarged by Edward R. Markham. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1919. 418 pp., illus., tables, 8 x 5 in., cloth, $1.75.

This is a textbook to accompany a course in forge practise, which explains the principles and provides a suitable set of exercises, but does not attempt to give minute instructions for making tools. The present edition has been enlarged by the inclusion of instruction in the heat treatment of steel.

FURTHER INCIDENTS IN THE LIFE OF A MINING ENGINEER.

By E. T. McCarthy. Lond., George Routledge and Sons, Ltd.; N. Y., E. P. Dutton & Co., 1920. 400 pp., por., 9 x 6 in., cloth, $7.00. (Gift of E. P. Dutton & Co.)

The success of Mr. McCarthy's previous volume, "Incidents in the Life of a Mining Engineer", has caused him to continue his account of his travels in little known countries. In "Further Incidents" he describes his adventures in Yucatan, Swaziland, China, the Malay States, Dutch West Borneo, Korea, Siberia and Siam.

As was the case with its predecessor, the proceeds of the sale of the book will be devoted to the St. Dunstan's Hospital for the Blind.

HAND BOOK OF NATURAL GAS.

By Henry P. Westcott. Third edition, 1920. Erie, Penn., The Metric Metal Works. 725 pp., illus., plates, charts, tables, 8 x 5 in., cloth, $3.75.

The intention of this work is to supply a one-volume manual covering the entire industry in a practical way. It begins with a brief statement of the geology of the gas fields, followed by a history of the industry and then proceeds successively to the properties of gases, field work, measurement of gas wells, pipe line construction and capacity gas compression, measurement, regulation, distribution and consumption. Casing head gasoline, the carbon black industry, helium and acetylene welding are also discussed. The present edition has been revised and enlarged.

HARDENING, TEMPERING, ANNEALING AND FORGING OF STEEL.

Including Heat Treatment of Modern Alloy Steels. A Complete Treatise on the Practical Treatment and Working of High and Low Grade Steel, comprising the Selection and and Identification of High and Low Carbon Steel, and Modern Chrome-Nickel and Chrome-Vanadium Alloys; the Most Modern Hardening, Tempering, Annealing and Forging Processes, the Use of Gas Blast and Electric Furnaces, and Heating Machines.

By Joseph V. Woodworth. Fifth edition. N. Y., The Norman W. Henley Publishing Co., 1919. 321 pp., illus., tables, 9 x 6 in., cloth, $3.

The author has prepared a compendium of practical information on the subjects mentioned, based on trade literature and personal experience, for the use of mechanics and other users of steel. The present edition has been revised and enlarged, and a section treating of the newer alloy steels has been added.

INTERNAL-COMBUSTION ENGINES.

Their Principles and Application to Automobile, Aircraft and Marine Purposes. By Wallace L. Lind. Boston, Ginn & Co. (copyright 1920). 225 pp., illus., chart, 8 x 6 in., cloth, $2.20.

This is a brief, practical, up-to-date text for students, covering the theory and operation of these engines, but omitting the question of design.

A KINETIC THEORY OF GASES AND LIQUIDS.

By Richard D. Kleeman. First edition. N. Y., John Wiley & Sons— Inc.; Lond., Chapman & Hall, Ltd., 1920. 272 pp., tables, 8 x 5 in., cloth, $3.00.

The object of this book is to formulate a kinetic theory of certain properties of matter, which shall apply equally well to matter in any state. By considering atoms or molecules as mere centers of forces of attraction and repulsion, instead of as elastic spheres and by modifying the definition of the free path of a molecule so that the exact nature of molecular interaction is not involved, it is possible to lay the foundation of a general kinetic theory which applies to matter in any state, and which furnishes a number of important formulas.

PIEUX ET SONNETTES.

By Edouard Noe and Louis Troch. Paris, Gauthier-Villars et Cie, 1920. 348 pp., illus., 10 x 7 in., paper, 20 francs, plus 50 per cent temporary increase

This work is a theoretical and practical discussion of piles and pile-driving, intended for engineers and architects. The first chapter treats of wooden piles, the second of metallic piles and the third of the different varieties of concrete piles, their advantages and disadvantages. Chapter four discusses metal sheet-piling. The theory of pile-driving is then studied, followed by a description of the various types of pile-drivers and of the method of driving by means of a water-jet. The volume ends with a study of the equilibrium of piles and notes on the proper choice of piles.

THE RUNNING AND MAINTENANCE OF THE MARINE DIESEL ENGINE.

By John Lamb. Lond., Charles Griffin & Co., Ltd.: Phila., J. B. Lippincott Co., 1920. 231 pp., illus., plates, 7 x 4 in., cloth, 8s 6d. (Gift of J. B. Lippincott Co.)

This is a practical manual, intended to prepare marine engineers who have not had previous experience with oil engines, so that they can qualify for positions on motorships. For this purpose the author describes the usual types of marine Diesel engines, the defects which have developed during operation and the methods that he has used to remedy them.

TECHNICAL WRITING.

By T. A. Rickard. First edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 178 pp., 8 x 5 in., cloth, $1.50.

Mr. Rickard's primary object is to awaken the interest of engineers in the importance of the proper use of language. His volume is a discussion of the subject, in which particular attention is given to the usual faults of technical writing, as he has observed them during his long experience as an editor. His rules are simple and definite, and their use is illustrated by numerous examples, so that the book will prove a useful guide to authors.

A TEXT-BOOK OF INORGANIC CHEMISTRY.

Edited by J. Newton Friend. Volume IX, Part 1. Cobalt, Nickel, and the Elements of the Platinum Group. By J. Newton Friend. Lond., Charles Griffin & Co., Ltd., Phila., J. B. Lippincott Co., 1920, 367 pp., tables, 9 x 6 in., cloth, 18s.

This instalment of this important reference work covers the eighth group of the Periodic Table, with the exception of iron. Like the previous volumes, it gives a concise, yet full, account of our present knowledge of these elements and their inorganic compounds, accompanied by numerous references to the leading works and monographs that treat of them.

ZINC AND ITS ALLOYS.

By T. E. Lones. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd. 127 pp., illus.; plate, 7 x 5 in., cloth, 2s 6d.

This is a concise, readable account of the occurrence, recovery and uses of zinc, intended for persons engaged in the zinc trade or in search of general information about the metal.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Chicago.—May 12, 1920, Fullerton Hall, Art Institute. Joint meeting with Electrical Section of Western Society of Engineers. Election of officers as follows: Chairman, J. R. Bibbins; Secretary, M. M. Fowler. Subject: "City Building and Transportation." Speaker: Mr. J. R. Bibbins, of The Arnold Company, Chicago. Attendance 250.

Denver.—May 8, 1920, Kenmark Hotel. Business meeting and election of officers as follows: Chairman, D. C. McClure; Vice-Chairman, J. C. Lawler, Secretary-Treasurer, R. B. Bonney. Attendance 28

Detroit-Ann Arbor.—May 12,1920, Board of Commerce. Subject: "The Electric Furnace in the Metallurgical Industry." Speaker: E. L. Crosby, of the Detroit Electric Furnace Co. Attendance 65.

Erie.—May 17, 1920, Commerce Rooms. Subject: "Some Present Day Problems in Engineering Research." Speaker: Professor V. Karapetoff, of Cornell University. Attendance 55.

Indianapolis-Lafayette.—May 21, 1920, Subject: "The Coming Science of Acoustical Engineering." Speaker: Professor V. Karapetoff, of Cornell University. Attendance 50.

Madison.—June 2, 1920, Engineering Bldg., University of Wisconsin. Election of officers as follows: Chairman, G. C. Neff; Secretary, H. M. Crothers. Subject: "Submarine Detection." Speaker: Professor M. Mason, of the University of Wisconsin. Attendance 30.

Panama.—May 8, 1920, Balboa Heights, C. Z. Subject: "Light, Lamps and Lighting Accessories." Speaker: Robert E. Hattis. A moving picture film showing the method of manufacturing National Mazda Lamps was projected and 31 views showing installations by the National X-Ray Reflector Company were shown. Attendance 20.

May 22, 1920, Hotel Corco, Panama. Business meeting and election of officers as follows: Chairman, Baxter R. Grier; Vice-Chairman, Elbert C. McDonald; Secretary-Treasurer, M. P. Benninger. Attendance 26.

Philadelphia.—June 7, 1920, Howard McCall Field. The afternoon was given over to golf. quoits and tennis matches between individual members, and two baseball games, followed by annual dinner, and election of officers as follows: Chairman, Chas. E. Bonine; Managers, C. W. Fisher, Baxter Reynolds, L. J. Costa and W. D. Carr; Secretary, R. B. Mateer. Attendance 117.

Pittsburgh.—May 11, 1920, Chamber of Commerce. Subject: "Ship Propulsion." Speaker: W. E. Thau, of the W. E. & M. Co. Attendance 57.

Pittsfield.—May 27, 1920, Masonic Temple. Subject: "What Industrial Workers are Really Thinking About." Speaker Mr. Whiting Williams. Director of Personnel, Hydraulic Press Steel Co., Cleveland, O. Attendance 200.

Portland.—May 11, 1920, University Club. The tentative program for the Pacific Coast Convention was discussed. Subject: "The Swan Island Project." Speaker: Mr. Robert G. Dieck. Refreshments were served. Attendance 51.

Seattle.—May 18, 1920, Arctic Club Assembly. Business meeting, followed by presentation of paper on "Methods Used in Laying Submarine Cables," by Mr. H. J. Sheppard, of The Pacific Tel. & Tel. Co. Attendance 75.

Toronto.—May 7, 1920. Engineers' Club. The meeting took the form of a "Question Box" discussion on a number of subjects suggested by the local members as follows: Wireless Transmission, A-C. Generators, Induction Generators, Rates for Electrical Energy, Relationship Between Technical and Commercial Phases of Electrical Industry, and Power Transformers. Attendance 68.

Worcester.—May 25, 1920, Worcester Polytechnic Institute. Subject: "Notes on Electric Power Conditions During the War, in New England and on the Pacific Coast." Speaker: Mr. George F. Sever. Attendance 55.

PAST BRANCH MEETINGS

Carnegie Institute of Technology.—May 27, 1920, Machinery Hall, C. I. T. Election of officers for 1920-21 as follows: Chairman, A. J. Hanks; Vice-Chairman, E. A. Brand; Secretary, W. S. Andrews. Subjects of the meeting: "Electrification of Railroads" by L. H. Hale '20, and "New Possibilities in Hydro-Electric Development" by F. I. Lawson '20. Attendance 60.

University of Cincinnati.—May 25, 1920, Engineering Building. Subject: "What is Electricity." Speaker: C. W. Coleman. University of Cincinnati. Attendance 72.

University of Kentucky.—May 12, 1920, Mechanical Hall. Business meeting, followed by a talk on "Inductive Effects of Transmission Lines" by Professor E. A. Bureau. Attendance 20.

University of Maine.—May 26, 1920, Lord Hall. Election of officers as follows: Chairman, Conan Priest; Secretary, Foster B. Blake; Treasurer, Virgin Trouant. Talks as follows: "Application of Electricity to Practical Lines" and "The Relation of the Engineer to His Work" by Mr. Davis of the B. R. & E. Co.; "Paper Making" by I. E. Craig. Attendance 28.

Massachusetts Institute of Technology.—May 27, 1920, Boston, Mass. Annual banquet; installation of new officers as follows: Chairman, D. B. McGuire; Secretary, M. C. Hall; Treasurer, L. R. Janes. Addresses were given by Acting President Elihu Thomson. Prof. D. C. Jackson and Prof. W. H. Timbie. Short talks were given by Professors A. E. Kennelly, W. S. Franklin, T. H. Dillon, and the incoming officers. Attendance 100.

Michigan Agricultural College.—June 3, 1920, Olds Hall of Engineering. Subject: "Direct-Current Machine Design." Speaker: Mr. H. L. Smith, of the Howell Motor Co., Attendance 24.

University of Michigan.—May 26, 1920, Engineering Bldg. Business meeting and election of officers as follows: Chairman, L. E. Frost; Vice-Chairman, J. H. Pilkington; Secretary, Leon A. Sears; Treasurer, M. B. Covill. Attendance 15.

School of Engineering of Milwaukee.—May 21, 1920. Subject: "Fundamental Principles of Modern Telephony." Speaker: Mr. W. J. Elmore, of the Wisconsin Telephone Co. Attendance 41.

Montana State College.—June 7, 1920, Assembly Hall. Subject: "Industrial Relations." Speaker: Mr. A. D. Stuart of the W. E. & M. Co. Attendance 77.

June 9, 1920.—Electrical Lecture Room. Election of officers as follows: Chairman, John L. Hastings; Vice-Chairman, Fred Cruzen, Secretary, J. A Thaler. Attendance 37.

University of North Carolina.—May 10, 1920. Subject: "The Grounding of Secondaries." Speaker: Mr. L. V. Sutton, of the Carolina Light & Power Co. Attendance 42.

May 31, 1920. Subjects: "Methods of Predetermining Motor Characteristics" by W. E. Merritt, and "The Senior Project" by C. M. Hazelhurst. Attendance 54.

Ohio State University.—May 25. 1920, Ohio Union. Banquet, at which election of officers for 1920-21 was held as follows: Chairman, S. S. Hunt; Vice-Chairman, J. C. Steffan; Secretary-Treasurer, R. H. Kaspar. The members then adjourned to Robinson Laboratory where an illustrated talk on "Automatic Telephone Circuits" was given by Mr. S. B. Williams, of the Western Electric Co. Attendance 34.

University of Oklahoma.—May 26, 1920, Engineering Bldg., Election of officers as follows: Chairman, M. G. Ross; Vice-Chairman, Archie Wallace; Secretary, Virgil Pendleton; Treasurer, Fred Huckaby. Attendance 39.

University of Pennsylvania.—May 10, 1920, Subjects: "Electrical Precipitation" by Mr. Shakeshaft, and "Household Electrical Appliances" by Mr. Zippler.

May 17, 1920. Subject: "Transmission Lines" by Mr. Greenstein.

May 24, 1920. Subject: "Development of Transformer" by Mr. Ten Broek. Total attendance 150.

University of Pittsburgh.—May 18, 1920. Paper: "Wireless Telephony." Speakers: Messrs. G. B. Anderson and J. C. Wolfe. Attendance 28.

May 25, 1920. Paper: "Vacuum Tubes." Speakers: Messrs. C. R. McGann and W. B. Jones. Attendance 25.

Purdue University.—April 20, 1920, Electrical Building. Three reel motion picture entitled: "The Story of a Fire" was presented by the Goodyear Rubber Company. Attendance 89.

May 22, 1920, Electrical Building. Subject: "The Coming Science of Acoustical Engineering." Speaker: Professor V. Karapetoff, of Cornell University. Attendance 95.

Stanford University.—April 28, 1920. Subject: "The Electrical Engineering of Radio Telegraphy." Speaker: Mr. Pratt, of the Federal Telegraph Company. Attendance 22.

University of Texas.—May 8, 1920. An interesting program on Electric Railways was given by the committee in charge, and Prof. J. M. Bryant gave a short interesting talk on "Where the Nickle Goes." A paper on "The Development of the Electric Locomotive" was presented by Mr. E. P. Price, and another on "The Development of the Electric Locomotive for Passenger Service on the Mountain Division of the C. M. & St. Paul Railway" was read by Mr. L. B. Walker. Both of these papers were illustrated by lantern slides. Mr. W. J. Weeg gave an interesting talk on "Alternating Current vs. Direct Current for Electric Railways. Attendance 21.

Virginia Military Institute.—June 2, 1920, organization meeting. Election of officers as follows: Chairman, H. C. Land; Secretary-Treasurer, L. Womeldorf. Attendance 17.

University of Washington.—May 4. 1920, Forestry Hall. Subject: "Electrification of the Chicago, Milwaukee & St. Paul Railway." Speaker: Mr. A. B. Van Dusen. Mr. Van Dusen illustrated his lecture with about one hundred slides. A three reel film entitled "The King of the Rails" was also shown. Attendance 91.

Washington State College.—May 14, 1920, Mechanic Arts Bldg. Business meeting, and election of officers as follows: Chairman, Chester H. Eitel; Secretary, Albert Hanson; Treasurer, Claude Kriesher. Attendance 16.

University of Wisconsin.—April 14, 1920. Engineering Bldg. Subject: "Central Stations Problem." Speaker: Mr. Newton, of the Madison Gas & Electric Company. Attendance 35.

May 12, 1920, Engineering Bldg. Subject: "Electric Train Control in the New York Subways." Speaker: Mr. Harold P. S. Day. Attendance 40.

June 9, 1920, Engineering Bldg. Election of officers for 1920-21 as follows: Chairman, R. E. Hantzsch; Secretary-Treasurer, E. D. Johnson.

Yale University.—May 18, 1920, Dunham Laboratory of E. E. Subject: "The Stevenson Power Plant." Speaker: Mr E. J. Amberg, of the Connecticut Light & Power Company. Attendance 150.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held on June 7 and 21, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

Recommended by the Board of Examiners June 7, 1920

To Grade of Fellow

FERNOW, BERNHARD E., JR., Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

PIERCE, ARTHUR G., Manager, Central District, Cutler-Hammer Mfg. Co., Pittsburgh, Pa.

RICE, RALPH H., Principal Assistant Engineer, Board of Supervising Engineers, Chicago, Ill.

To Grade of Member

BARRON, JACOB T., General Supt. of Production, Public Service Electric Co., Newark, N. J.

BATCHELLER, WILLIS T., Electrical and Mechanical Engineer, Seattle Municipal Light and Power System, Seattle, Wash.

BROWN, L. E., Superintendent, Springfield Light, Heat & Power Co., Springfield, O.

HILL, WILLIAM S., Supt. Light & Power, Springfield Gas & Electric Co., Springfield, Mo.

KILNER, RALPH H., Commercial Engineer, Westinghouse Electric & Mfg. Co., Chicago Ill.

KOONTZ, JOHN A., JR., Electrical Engineer, Great Western Power Co., San Francisco, Cal.

MCKENZIE, DANIEL A., Asst. Engineer, Operating Dept., Hydro-Electric Power Commission, Toronto, Ont.

O'CONNELL, WILLIAM T., Estimator & Designer, Elec. Div., Panama Canal, Balboa Heights, C. Z.

PEARCE, WALTER C., Supt., Electric Dept., Syracuse Lighting Co., Syracuse, N. Y.

PRINDLE, EDWIN J., Senior Partner, Prindle, Wright & Small, New York, N. Y.

SMITH, HAROLD L., Designing Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

WESTMAN, ADOLF J., Electrical Engineer, Montreal Tramways Co., Montreal, Canada.

Recommended by the Board of Examiners June 21, 1920

To Grade of Fellow

BEEUWKES, REINIER, Electrical Engineer, Chicago, Milwaukee & St. Paul R. R. Co., Seattle, Wash.

MORTON, ROBERT B., Electrical Engineer with Toltz, King & Day, St. Paul, Minn.
MURPHY, GEORGE R., Manager, Pacific District, Electric Storage Battery Co., San Francisco, Cal.

To Grade of Member

BAKER, FRANK J., Vice-President, Public Service Co. of Northern Illinois, Chicago, Ill.
BALDWIN, ROBERT L., Electrical & Mechanical Engineer, Burns & McDonnell, Kansas City, Mo.
BARNES, DONALD C., Manager, Seattle Division, Puget Sound Power & Light Co., Seattle, Wash.
BERGSTROM, CARL O., Manager, Electrical Dept., B. F. Sturtevant Co., Hyde Park, Mass.
BRILL, OSCAR C., Office of Chief Engineer, American Telephone & Telegraph Co., New York, N. Y.
DURAND, WILLIAM F., Professor of Mechanical Engineering, Standford University, Stanford University, Cal.
EVANS, CLARENCE T., Development Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
EVANS, LLEWELLYN, Superintendent of Electric Works, City of Tacoma, Wash.
FAWELL, THOMAS A., Chief Draftsman, Anderson, Meyer & Co. Ltd., Shanghai, China.
FERRIS, LIVINGSTON P., Electrical Engineer, Dept. of Development & Research, American Telephone & Telegraph Co., New York, N. Y.
GAFFEY, JOHN J., Assistant Engineering Manager, Harry M. Hope Engineering Co., Boston, Mass.
HURLEY, WALLACE P., Sales Engineer, Westinghouse Electric & Mfg. Co., New York, N. Y.
McALPINE, DOUGALD D., Contract Engineer, Canadian General Electric Co., Toronto, Ont.
MILLER, ALVIN A., Manager, Power & Railway Divisions, Westinghouse Elec. & Mfg. Co., Seattle, Wash.
OETTING, O. W. A., Chief Engineer, Willard Storage Battery Co., Cleveland, O.
PACE, GORDON, District Operating Engineer, Hydro Electric Power Commission of Ontario, Toronto, Ont.
READ, ERNEST K., Circuit Breaker Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
ROBLEY, ROY R., Operating Engineer, Portland Railway, Light & Power Co., Portland, Ore.
VAN HORN, IRVING H., Physicist, Lamp Development Lab., National Lamp Works of General Electric Co., Nela Park, Cleveland, O.
WARNER, RUSSELL G., Instructor in Electrical Engineering, Yale University, New Haven, Conn.
ZIMA, LUDWIG A., Assistant Cable Engineer, Interborough Rapid Transit Co., New York, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member, objecting to the election of any of these candidates should so inform the Secretary before July 31, 1920.

Adams, Charles W., Saginaw, Michigan
Andres, Paul G., E. Lansing, Mich.
Bankus, John, Portland, Oregon
Benington, William F., Syracuse, N. Y.
Betts, Andrew G., Tacoma, Wash.
Blanton, Burt C., Dallas, Texas
Boring, Herbert A., Seattle, Wash.
Brainard, Charles D., Chicopee, Mass.
Brown, Robert Q., Seattle, Wash.
Bryant, Le Roy C., Chicopee, Mass.
Campbell, Allan B., Des Moines, Iowa
Carpenter, James W., St. Louis, Mo.
Casey, Francis, Chicago, Ill.
Chamberlain, Leon H., San Francisco, Cal.
Cobb, Frank E., St. Louis, Mo.
Cockburn, Donald, Boston, Mass.
Coffin, Frank C., Worcester, Mass.
Conrad, Lester L., Los Angeles, Cal.
Corson, Le Roy, Long Island City, N. Y.
Counts, Hilda, E. Pittsburgh, Pa.
Crawford, Vernon W., Pittsfield, Mass.
Denn, Edward J., Springfield, Mass.
Eckert, William S., Hastings-on Hudson, N. Y.
Edwards, Weightman, New York, N. Y.
Fairfield, Donald H., Kenosha, Wis.
Fisher, William H., Akron, Ohio
Fleming, Samuel W., Harrisburg, Pa.
Fletcher, John A., Vancouver, B. C.
Flowers, William E., (Member), Atlanta, Ga.
Frankel, Charles B., Chicago, Ill.
Franklin, Townsend U., New York, N. Y.
Friday, Casper S., Schenectady, N. Y.
Gifford, Clarence C., San Pedro, Cal.
Glass, Howard G., Baltimore, Md.
Godwin, Jimmie J., St. Louis, Mo.
Govier, Charles E., State College, Pa.
Grant, Royal E., Dracut, Mass.
Gregory, Philip S., Montreal, Quebec
Guy, Richard W., Ottawa, Canada.
Henyan, George W., Schenectady, N. Y.
Herrold, Charles D., San Jose, Cal.
Hills, Charles B., Bathurst, N. B.
Hobson, Albert, Dallas, Texas
Hofert, Fred A., Chicago, Ill.
Hood, Clifford F., Worcester, Mass.
Hopkins, Henry D., Akron, Ohio
Hrubes, James A., Chicago, Ill.
Hubbert, William, Seattle, Wash.
Hult, George A., Sioux Falls, S. Dak.
Insel, Emanuel M., New York, N. Y.
Irland, George A., Sparrows Point, Md.
Jahn, Emil, New York, N. Y.
Jansky, Cyril M., Jr., Minneapolis, Minn.
Johnson, Clarence L., San Francisco, Cal.
Johnson, Tomlinson F., Jr., (Member), Atlanta, Ga.
Kawabata, Itsuo, Boston, Mass.
Keiser, William P., St. Louis, Mo.
Krasnoff, Nathaniel, Annapolis, Md.
Kyle, George L., Niagara Falls, N. Y.
Lane, Robert S., Orange, N. J.
Lang, William I., Jr., New York, N. Y.
Lindell, Arthur G., Chicago, Ill.
Malloy, William E., New York, N. Y.
Manchester, Mark D., (Member) Dawson, Yukon Territory
Meeker, Royal, Pittsfield, Mass.
Merrill, Zadoc E., Olympia, Wash.
Meyer, Grover C., New York, N. Y.
Millan, A. M. M., Seattle, Wash.
Moses, Marcus H., New York, N. Y.
McCain, Vernon E., Tacoma, Wash.
McFarland, George I., Salt Lake City, Utah
McKeen, Ernest E., Portland, Oregon
McKenzie, Ernest F., Schenectady, N. Y.
O'Brien, Brian, New Haven, Conn.
O'Leary, Joseph T., New York, N. Y.
Peck, Henry S., (Member), Seattle, Wash.
Pilcher, Basil B., Philadelphia, Pa.
Ploetz, Charles M., Milwaukee, Wis.
Prescott, Clifton S., Chicago, Ill.
Price, Tyler, G., Chicago, Ill.
Pritzker, Asher, Toronto, Ont.
Quinn, John T., New York, N. Y.
Rhudy, James T., Lexington, Va.
Roddey, Marvin M., Cleveland, Tenn.
Roell, Frank A., Seattle, Wash.
Ryder, Harry M., E. Pittsburgh, Pa.
Rurey, Burdett F., Shorewood, Wis.
Schweizer, Albert C., New York, N. Y.
Scott, James P., Pittsburgh, Pa.

Self, Wayne K., Weirton, W. Va.
Shoemaker, Guy T., (Member), Davenport, Iowa
Skinner, William E., Milwaukee, Wis.
Smallidge, Frank E., Wenatchee, Wash.
Smith, David M. B., McGill, Nevada
Starkey, William C., Mansfield, O.
St. Clair, Harry, Chattanooga, Tenn.
Tait, Andrew S., (Member), Montreal, Que.
Thompson, Charles S., Wilmington, Del.
Underwood, Cecil H., Schenectady, N. Y.
Vodicka, Frank J., Edgewood, Pa.
Wagner, C. E., Portland, Oregon.
Watson, Leon A., Cleveland, Ohio
Waugh, Louie E., Detroit, Mich.
Webster, Clarence A., Hog Island, Pa.
Webster, Marshall, Oak Park, Ill.
Wessels, Louis H., Kearny, N. J.
White, Bryant, (Member), Lynchburg, Va.
Whiteman, Ralph A., Johnstown, Pa.
Widrig, John, Seattle, Wash.
Wiggin, Parker E., E. Pittsburgh, Pa.
Williamson, Harold P., Chicago, Ill.
Winter, Parker D., Wenatchee, Wash.
Wolfe, Nelson B., New York, N. Y.
Wood, Harold B., Roundup, Mont.
Woodcock, Vincent J., Worcester Mass.
Total 115

Foreign

Andrews, B. Harding, Frankton, N. Z.
Arnold, Hugh T., Manchester, Eng.
Bickerstaff, Ernest, Addington, Christchurch, N. Z.
Bowles, Cecil J. V., (Member), Parnahyba, Sao Paulo, Brazil
Briggs, Arthur P., Barranquilla, Colombia, S. A.
Bunyard, Frederick C., Cambridge, N. Z.
Chacon, Fernando E., Santiago, Chile, S. A.
Correia, J. N., Lisbon, Portugal
Gomes, Francisco, Rio de Janeiro, Brazil
Gosset, Edward L., Tauranga, N. Z.
Howgrave-Graham, Robert P., London, Eng.
Ingleby, Henry S., (Member), Leeds, Eng.
Kahn, Max, Birmingham, Eng.
Kojima, Tatsu, Kobe, Japan
Mandeno, Lloyd, Tauranga, N. Z.
Mitchell, Robert B., (Member), Glasgow, Scotland
Niwa, Yashujiro, Tokyo, Japan
Orme, Basil S., (Member), Manchester, Eng.
Portengen, J. A., Soengeiliat, Banka, Dutch E. Indies
Radbone, Victor J., London, Eng.
Reyes, Ceasar A., Rancagua, Chili, S. A.
Schulz, Thomas N., (Fellow), Kristiania, Norway
Tang, Min K., Kiangpeh City, Chungking, China
Tseng, Chou C., Peking, China
Varma, Ganesh L., Ajmer-Rajputana, India
Wilford, George McL., Wellington, N. Z.
Wilmot, Louis B., (Fellow), Johannesburg, S. A.
Total 27

STUDENTS ENROLLED JUNE 30, 1920.

11576 Hale, Laurence H., Carnegie Institute of Technology
11577 Schweitzer, George E., Pennsylvania State College
11578 Nelson, Clyde A., Pennsylvania State College
11579 Lyman, Arthur F., Wentworth Institute
11580 Bagg, Raymond J., Pratt Institute
11581 Greiner, Joseph A., Murray Hill Trade School
11582 Intemann, William F., Pratt Institute
11583 Mickey, Ralph S., Pennsylvania State College
11584 Moss, John, New York Electrical School
11585 Speir, William P., Georgia School of Technology
11586 Humrickhouse, Ralph R., Case School of Applied Science
11587 Porter, Frederick M., Lehigh University
11588 Pearson, James W., Johns Hopkins University
11589 Beck, Herbert H., University of Wisconsin

Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.

*Deceased.

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

Calvert Townley, Chairman, 165 Broadway, New York.
N. A. Carle, W. A. Hall, George A. Hamilton,
L. F. Morehouse, W. I. Slichter, C. E. Skinner.

FINANCE COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Hall, L. F. Morehouse.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
L. W. Chubb, E. E. F. Creighton, John H. Finney,
L. R. Jorgensen.
Chairman of Committee on Technical Activities, the chairmen of all technical committees, and the chairmen of all Sections.

PUBLICATION COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
N. A. Carle, Wm. A. Del Mar, F. L. Hutchinson
Harold Pender

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
H. N. Latey, J. H. Morecroft, Wm. S. Murray,
H. H. Norris, E. M. Sawtelle, Clayton H. Sharp,
Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, Murray & Tregurtha Corp., Atlantic, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd,
and the chairmen of all Institute Sections *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker,
Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose,
G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb,
A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins,
D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 111 Fifth Ave., New York.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, 644 Riverside Drive, New York.

H. V. Bozell	John B. Fisken,	W. S. Gorsuch,
L. G. Ireland,	A. H. Kruesi,	J. F. Meyer,
S. G. Rhodes,	Allard Smith,	E. H. Sniffen,
	P. B. Yates.	

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.

C. R. Dooley,	F. F. Fowle,	Charles S. Howe,
C. E. Magnusson,	E. B. Merriam,	L. F. Morehouse,
G. H. Pfeiff,	H. W. Price,	R. F. Schuchardt,
W. I. Slichter,	William R. Work.	

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.

James Burke,	Alexander Churchward,	A. M. Dudley,
C. E. Eveleth,	G. Faccioli,	B. G. Lamme,
A. C. Lanier,	R. B. Williamson.	

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.

F. F. Ambuhl,	E. R. Berry,	Joseph L. Dixon,
I. R. Edmands,	L. E. Imlay,	F. A. Lidbury,
W. R. Whitney,	J. L. Yardley.	

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.

P. G. Agnew,	H. D. Arnold,	E. F. Burton,
L. W. Chubb,	J. C. Clark,	C. P. Eldred,
E. P. Hyde,	Chester W. Rice,	C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.

P. H. Adams,	E. V. Buchanan,	H. W. Cope,
Wm. E. Date,	James Dixon,	A. M. Dudley,
R. H. Goodwillie,	H. D. James,	W. C. Kalb,
R. H. McLain,	E. H. Martindale,	A. H. Timmerman,
L. E. Underwood,	H. Weichsel,	R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 124 E. 15th St., New York.

C. W. Baker,	Wm. M. Bradshaw,	H. B. Brooks,
F. P. Cox,	F. V. Magelhaes,	Charles Robbins,
	Clayton H. Sharp.	

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.

F. B. Crosby,	F. D. Egan,	Gordon Fox,
Eugene Friedlaender,	E. S. Jefferies,	W. C. Kennedy,
D. M. Petty,	Wm. T. Snyder,	Wilfred Sykes,
R. B. Williamson,	Fred H. Woodhull,	J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.

G. N. Chamberlin,	J. R. Cravath,	Terrell Croft,
N. S. Dickinson,	Bassett Jones,	F. D. Newbury,
P. G. Nutting,	R. C. Powell,	E. B. Rosa,
W. D'A. Ryan,	W. M. Skiff,	G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.

R. A. Beekman,	Eskil Berg,	A. R. Cheyney,
Maxwell W. Day,	E. G. Gallagher,	H. L. Hibbard,
W. F. James,	C. A. Jones,	C. S. McDowell,
W. P. Meschenmoser,	I. H. Osborne,	G. A. Pierce, Jr.
J. B. Porter,	L. B. Sinclair,	H. M. Southgate,
Wilfred Sykes,	W. E. Thau,	A. E. Waller
	F. W. Wood.	

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.

R. T. Andrae,	F. H. Armstrong,	Graham Bright,
L. C. Isley,	R. L. Kingsland,	A. B. Kiser,
Wills Maclachlan,	E. B. Woodward.	

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.

J. T. Barron,	A. E. Bauhan,	E. T. Brandon,
H. W. Eales,	W. L. R. Emmet	W. S. Gorsuch,
H. P. Liversidge,	I. E. Moultrop,	Frank D. Newbury,
H. S. Putnam,	R. F. Schuchardt,	Russell W. Stovel
H. L. Wallau.	R. B. Williamson.	

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.

G. E. Armstrong,	P. H. Chase,	W. H. Cole,

INSTITUTE REPRESENTATIVES

ON AMERICAN BUREAU OF WELDING

W. L. Merrill.

ON AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, Wm. S. Murray, F. N. Waterman.

ON AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart. C. E. Skinner.

ON AMERICAN YEAR-BOOK ADVISORY BOARD

Edward Caldwell.

ON BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon. Calvert Townley.

ON COMMISSION OF WASHINGTON AWARD

John Price Jackson, Charles F. Scott.

ON COUNCIL OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

H. H. Humphrey, John B. Taylor.

ON ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle, Charles S. Ruffner, C. E. Skinner.

ON ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

ON FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt L. B. Stillwell.

ON JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, Calvert Townley, E. W. Rice, Jr.

ON JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, Samuel Sheldon.

ON JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATOR PINS

J. T. Barron.

ON LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle, Samuel Sheldon, W. I. Slichter.

ON NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

ON NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood, Percy H. Thomas.

ON NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

ON NAVAL CONSULTING BOARD

Benjamin G. Lamme, Frank J. Sprague.

ON SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

P. G. Agnew, F. Conrad, F. P. Cox, F. C. Holtz, A. E. Kennelly, Farley Osgood, S. G. Rhodes.

ON U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.
Guido Semenza, N. 10 Via S. Radegonda, Milan, Italy.
Robert Julian Scott, Christchurch, New Zealand.
T. P. Strickland, 61 Hunter St., Sydney, N. S. W.

An Engineering Analysis of the Labor Problem

President's Address*

BY CALVERT TOWNLEY

THE Constitution prescribes that the President must deliver an address at the Annual Convention,—whether you want to hear it or not. It has been sometimes customary for the Executive who is about to retire from office to summarize the achievements of his term. It has seemed to me that these have been better chronicled as they occurred in the pages of your JOURNAL. The pastime of prophecy has some attractions, but is of doubtful value, and somewhat dangerous as well. The advances in the art are well covered by many valuable technical papers of the year including those which are to be submitted at this Convention. There remain broad public questions regarding which engineers are peculiarly well qualified to have opinions and to influence the opinions of others and it has therefore seemed to me that I might perhaps come nearer justifying the constitutional provision by dealing with one of these.

One of the most important problems which the American people now have to solve is that of the relations between the employer and the employee classes, generally referred to as capital and labor. A large measure of our national success will depend upon this solution, and as engineers are even more directly affected by and therefore more intimately connected with industrial prosperity than are the other professions, for example, of law, medicine and theology, it is more obviously their duty to assist in the solution of the problem as much as they can. Although this subject has been voluminously discussed by numberless people for a long time, it has usually been treated from the standpoint of what ought to be— according to the views of one or the other of the interested parties. Questions of justice and injustice, legality, the so-called "rights" of labor and the protection of capital, of expediency, are brought in. There is one angle from which, so far as I know, it has not been treated, namely from the standpoint of what is, instead of what ought to be; that is to say, from the engineering standpoint,—one of fact, human nature and of economic laws as contrasted with the laws enacted by man. It therefore may be now opportune, especially to this audience, to offer a contribution from this view point, with the belief that the direction of the attention of the members of our organization to the fundamentals of so important a question may serve to clear away some of the fog which always seems to becloud the view.

To begin with, the first law of nature is self preservation. It is manifested in its highest form as patriotism, in its lowest as sordid greed. Between these two extremes appear all forms of selfishness, many of them by no means blameworthy, others under control, or not infrequently dormant, but nevertheless certain to manifest themselves when circumstances compel. For example, selfishness is the actuating motive in barter. It leads the seller to try to sell at the highest price and the buyer to try to buy at the lowest. Barter and trade are at the foundation of industry and having been always recognized as essential to prosperity have been encouraged and protected. This form of selfishness has acquired great respectability—but while the practise of matching wits in trade is supported by the people of all lands, the sanctity of contract is also fundamental, *i e.*, that form of selfishness which leads to the violation of an agreement once made is everywhere decried and condemned. It has been demonstrated that selfish human nature will assert itself and that good faith cannot be relied upon, therefore recourse has been had to another powerful trait, fear. The exercise of the police power, with its penalties for tansgression, is based on fear of consequences.

The ideal condition for barter is where both parties are absolutely free agents and neither therefore under duress. Although such a condition is seldom realized, when the duress becomes so extreme as to constitute oppression, the desperation of the oppressed may be counted upon to devise resistance. Just as surely as political oppression has throughout all history led to political revolution, so has commercial oppression caused commercial revolution. Too great power, if continued long enough, will always be abused and just as such power in government becomes tyranny, similarly too great advantage in barter begets com-

*Delivered at the 30th Annual Convention of the A. I. E. E. White Sulphur Springs, W. Va. June 29, 1920.

mercial robbery. These statements sound like platitudes and I should hesitate to repeat them were it not for the fact that they not only bear directly on the present situation between labor, capital and the public but they seem to be so frequently forgotten or ignored. Please remember that I am not blaming or praising any one. I am trying to recite cold facts and to call things by their right names.

In the time-honored barter between employer and employee, the employer formerly held the strategic position. If he refused to pay the wages demanded by any individual there was usually some one else willing to accept a lower rate and the unemployed one, not being mobile and usually having to work to live, was soon forced to yield. As business concerns grew larger this advantage naturally increased and just as naturally the employers' power was abused. By and by the resulting oppression became sufficiently acute to provoke general resistance and the labor union came into being. Workmen banded together to eliminate competition among themselves. It should be noted that the establishment of unions did not suspend the operation the law of supply and demand; rather did it allow that law freer play by counterbalancing the power of the union against the previous strategic advantage of the employer. The effect was generally beneficial because it corrected an evil, and the general public while not particularly interested looked on approvingly. But early in their history the unions made a serious although not a surprising blunder. They set up a system of contracts between employer and employee and, because they could escape doing so, provided no means by which the workmen could be penalized for violation, except by the union itself. This flagrant flouting of a fundamental did not for a time have any serious effect, but the blunder once made was never thereafter corrected and it is probable that even today it would be difficult to find a labor leader who could be made to see the seriousness of this mistake, much less to endeavor to rectify it. I pass quickly over a long period of years after the first organization of unions during which unionism had its ups and downs and came to be regarded, if not with equanimity, at least with tolerance by the employer class, and come to the recent period of the World War. Here an entirely new condition was created—an imperative demand for men came up almost over night. It simply had to be satisfied at no matter what price. At the same time not only was the supply diminished by those required for the armed forces but immigration stopped as well. The effect on the price of labor was axiomatic—it rose. The unions being the vehicles through which the demands of many classes of workmen could most readily be expressed at once became active. The law of supply and demand was fighting on their side and they made the most of it. Wages and prices rose to hitherto unheard-of figures. Labor had too much power; its demands had to be met whether or no, and of course it abused its power. Then the unions made another mistake. They credited too much of their successes to their organization and failed to appreciate the part played by the law of supply and demand, also they underestimated the power of resistance which could be engendered by oppression. In their turn they became the oppressors—insistent, arrogant. Where their principal weapon, the strike, was not effective as against the employer class in one industry, they enlisted the workmen in other industries, and who had no grievance, in sympathetic strikes. They asserted their power to dominate the public convenience, safety and health in order to coerce their opponents into submission to their will. Were it necessary I could recite many specific instances to prove this fact but I assume it to be so generally known and accepted that a recital would be superfluous. Now this is the condition to day and it is one which has caused much grave concern and has produced many strange ideas. We hear that a new order of things has come to pass; that the "rights" of labor must now be respected; that the workman will hereafter have a greater share of the products of his toil; that he must share in the management of industry and have a recognized place in government, and the like. To my mind the facts warrant none of these assumptions. There is no new order,—economic laws are the same as they always have been. They are as ruthless and as inexorable as are the laws of physics. Neither has human nature changed. The unions are in the saddle, but, to use a hunting expression, they are riding for a fall. Please let me remind you again that I am not blaming the unions, or any one else. I am trying to confine myself to statements of facts and to logical opinions based thereon according to the precept and training of the engineer. Suppose we analyze the fundamentals.

In our system of govermnment where every man can vote and have his vote counted, and with our multitude of newspapers informing everybody of what is going on, there is little chance that a condition can arise such as that of China or of Russia or even of Germany. Further while we talk a great deal of politicians and parties, we know that on any really vital question the people are going to make up their minds themselves and will elect men who will carry out the wishes of the majority. In other words the great majority rules.

The number of workmen in labor unions is variously estimated to be from ten to forty per cent of the men employed in trades where there are unions. These figures represent the extreme claims of the contending parties. We shall probably not be far wrong if we take a compromise figure of say 20 per cent. In the largest class of all, the farmer there are no unions and similarly none in many other avocations, so if we consider the total voting strength of the country, the percentage of men in unions is certainly not over

10 per cent and probably not over 5 per cent. Of this small proportion a few are the leaders, a larger number enthusiastic followers and the great majority largely governed by conditions. By that I mean they are loyal unionists when the union is succeeding but desert on small provocation when it is defeated. This is almost obviously true because the workmen are banded together to accomplish selfish purpose and no other. The individual workman cares no more for his fellow as a class than does the employer. It follows therefore that a union must continue to succeed or it will disintegrate and disappear. The history of the last thirty years has recorded many once powerful unions even the names of which are now almost forgotten. The "Knights of Labor" and "The Amalgamated Association of Iron and Steel Workers" are two examples which illustrate this point. The strength of organization contending against the mob is very great and it is probably true that so small a proportion as ten per cent or even as five, would prevail under these conditions. That in fact is the situation confronting the nation today. This small organized percentage supported by the operation of the law of supply and demand has prevailed, but looking into the future, it seems clear that there is only needed a sufficient incentive to induce the unorganized 95 per cent, or even a small part of them, to get together in opposition to the five per cent in order that the latter may be overwhelmed. This incentive has been or will be furnished by union oppression. I say "has been or will be" because the abuse of too great power always grows. Therefore if the unions shall still continue to gain their ends, even in the face of their present insolence and ruthless disregard of others, their arrogance and self confidence born of such successes, will inevitably lead them on to acts of greater and yet greater oppression until they force their opponents to combine against them for defense or even for self preservation. The moneyed class never has had, and probably never will have much sympathy or cooperation from the general public for the very obvious reason that the general public is jealous of it. Sympathy goes naturally to those who are worse off. The moneyed class being better off than the great majority therefore comes in for sympathy with a minus sign, that is, jealousy. An incentive which will induce the public to oppose the unions can therefore be sufficient only when the reason is strong enough to overcome this jealousy. That reason becomes sufficient when the need for self preservation is made clearly apparent. Already there are indications that the people will not much longer submit to domination by the unions. The Governor of Massachusetts defied them, was shortly thereafter reelected by an abnormally large majority and has now been nominated on the Republican National ticket for Vice-President which latter distinction it is safe to say he owes almost entirely to this incident. The State of Kansas has enacted a law to curb union interference with the peace and comfort of her citizens and her Governor has become a popular National figure in consequence. The temper of much of the daily press has changed, and where formerly there was much said about the so-called "living wage" and criticism of "capitalistic greed" "there now appear articles about the vicious cycle of mounting wages and costs", "loafing on the job" and the "need to teach the people thrift and economy". These and other signs are merely symptoms of the incentive to resistance that may be expected to be superinduced by oppression. The aroused public would not be just to the unions, and an attack once thoroughly launched might be expected to go further than it should. However I am not here discussing justice or how either party should behave but rather what they have done in the past and under pressure of human nature and economic laws most certainly will do in the future.

Whether or not an aroused public does curb union domination, the present high wage era will not be radically affected. That is a condition controlled, not by the unions at all, but by the law of supply and demand. Even the complete abolition of the unions while it might check further increases and perhaps bring about some recessions, and while it would reduce living costs some what by cutting out interruptions, and tend to increase production, would not itself either increase the supply of workmen available nor decrease the demand for their services. Indeed while I have discussed the fundamentals of barter between the employer and the employee and have endeavored to show the natural reactions resulting from barter with either party under duress, it is not at all certain that conditions will become so extreme as to bring about the reaction described. That is to say, instead of the abuse of power by the unions being curbed by the organized opposition of other classes of our people it may be reduced or even thwarted by the operation of the law of supply and demand. Lest I may be misunderstood I might here state that because I have been confining myself to a discussion of the relations between the employer and the employee and have had much to say about the employee's abnormally high wages, I do not want to be understood as giving that condition as the only cause of the prevailing high prices. Advantage has very generally been taken of the opportunity to increase profits by those who had wares to market, which is only another way of saying again that selfishness is a universal trait of which no class or classes has a monopoly. A bettering of conditions may be affected by a decrease in the demand for or an increase in the supply of labor. Already there is a marked reduction in the sales of certain products resulting from an unwillingness or the inability of many people to pay the exorbitant prices asked. Government re-

ports of falling exports indicate that the expected lessening of the foreign market for our high priced products is approaching and it is not at all unlikely that this may be followed by heavy increases in our imports which will displace American made goods. This result may come about both because foreign nations are getting into their stride of production again and because the high prices prevailing here have naturally created an attractive market. A combination of these and other conditions will reduce the demand for our products and consequently for the workmen to produce them. The immigration authorities of the port of New York report their facilities overtaxed to handle the large numbers coming to our shores, and say that even those numbers would be far larger if there were only more ships to carry the people who want to come. It is natural to suppose that as the heavy burdens of after-war taxation are brought home to the foreign people an increasing percentage will seek to escape them by coming here to live, and also that the gradual restoration of trans-Atlantic shipping to its normal schedules will afford the greater facilities thus demanded. This augmentation of population—largely workmen of course, will swell our supply and likewise tend to correct any shortage that may exist.

If my analysis of the facts is correct, it is clear that the present domination by organized labor is temporary and also that the era of high prices will pass. Therefore, no material permanent change in either our social order or in our industrial stucture is to be anticipated. In the contest between brains and brawn, waged since the world began, brains have always won and brains always will. Free play for the natural forces of trade may be counted upon to exercise a beneficent influence and it should be hampered and interfered with by government restrictions as little as possible. We cannot of course determine from history or from any facts at hand, how long a time it will take for conditions to become normal again but what we need now is clear thinking, courage and patience. I know that we can rely on the engineer for clear thinking and I haven't the slightest doubt about his courage, but I am not so sure about his patience. You should be leaders of thought in your several circles. You can help to allay much of the present anxiety about the so-called unrest and the apprehension as to the future; therefore I feel warranted in asking you to give your close consideration to the subject matter of what I have said this morning.

CORRESPONDENCE

TRANSMISSION OF MUSIC BY RADIO

To the Editor

In the July number of the JOURNAL under caption "The Transmission of Music by Radio" is described a recent transmission of music giving the impression that the possibility of this method resulted from research work at the Bureau of Standards, Washington, D. C. As a matter of record, perhaps the first radio telephone transmission in this country was that of music in the spring of 1907, from the old building at the corner of 39th Street and Broadway, which housed the Telharmonium apparatus. The radio music there transmitted was first "picked up" at the Brooklyn Navy Yard by Mr. George Davis, then Chief Electrician in charge of radio.

In 1909 radio music was sent out from my laboratory at 103 Park Avenue; Mme. Mazarin, of the Manhattan Opera Company singing on one occasion the "Haberana" from Carmen, to a select radio audience in Newark. A little later a temporary installation was made on the roof of the Metropolitan Opera House, and music picked up by microphones on the stage was sent out.

During the summer and fall of 1916 regular nightly "concerts" of phonograph music were maintained at the Highbridge Radio Laboratory, this music being heard at that time as far as Buffalo. Parties in New Jersey danced to this music played 35 miles away.

Since last winter radio music from Ossining has frequently been heard in Chicago and at points even farther west. From the stage of the California Theatre at San Francisco daily and nightly distribution of music from a 50-piece orchestra has been carried on for the past two months. This music has been heard in St. Paul, Minn.

LEE DEFOREST

ELECTRON TUBES AS DETECTORS

The currents which electric waves produce in radio receiving apparatus are extremely small and alternate at very high frequencies. Because of the rapid reversals and the feebleness of these currents, they cannot be detected by ordinary electric-current indicating instruments, and special apparatus must be provided for this purpose. This is usually designed to convert these currents into a form which can be detected with a sensitive galvanometer or telephone receiver.

One device for this purpose is the electron tube, sometimes called an audion, which has entirely replaced the crystal detector formerly used. There is a need for exact knowledge of the properties and behavior of electron tubes, in order to secure such designs as will work most effectively in a particular circuit. Methods of measurements have been devised and an investigation carried out at the Bureau of Standards, as a result of which the mode of action of these tubes as detectors has become more definitely known. A special form of electric measuring bridge has been constructed, by means of which the four coefficients upon which the action of the tube depends are easily measured.

Information on this and other work on electron tubes is included in a treatise on the subject which is now in preparation by the Bureau of Standards.

Sawmill Refuse, Powdered Coal, and Oil Fuels

BY DARRAH CORBET

Charles C. Moore & Co., Seattle

THE writer realizes in attempting to present any paper on as broad a subject as seems to be indicated by the one in hand that of necessity a great deal will have to be omitted and many subjects touched on but briefly which could well be analyzed to great length.

There are three fuels under consideration—saw-mill refuse, powdered coal, and oil. On the first of these fuels there is available comparatively little authentic information. On powdered coal a great deal has been written, and although this fuel has been in use for twenty years or more it is only just recently that successful installations have been made in power plants, and it is only in such installations that the writer will interest himself in this article. On oil fuel on the other hand a great deal has been written and a great many data are available. This fuel has been used for a long time and probably on account of its convenience and very extensive use in certain sections and on account of the accuracy with which determinations can be made when using this fuel, data have been compiled for operations and tests under almost every conceivable condition.

On account of the recent very rapid increase in the costs of coal and oil fuel there has been a strong tendency, particularly on the Pacific Coast, towards the use of sawmill refuse fuel. This fuel is probably available in larger quantities in this Northwestern territory than in any other part of the world at the present time and it would certainly seem that it was high time that use was made of this fuel, which for years and years has been wasted and has been a really heavy expense to the producers in ridding themselves of it.

The writer intends to analyze more particularly at this time sawmill refuse fuel and the results that have been secured with its use in such installations as are able to furnish us with data. As previously stated the available information on this subject is not very extensive and we wish you would bear this in mind and realize that later experiments and tests may indicate that results can be secured different from and far better than those referred to herein.

In the case of oil fuel, that secured from one locality does not differ very greatly from that secured from another, percentages of moisture and foreign matter vary slightly and the heat units per pound also vary a little but the general characteristics of the fuel, the method of firing it, applies equally well to one oil or another. On the other hand coal fuel is recognized as having a considerable variation, coals are graded according to fineness. They also vary materially as to the number of heat units per pound, as to the amount of foreign matter and ash present in the fuel and as to their characteristics in burning. We refer to them as anthracite, bituminous, sub-bituminous, lignite, etc. Some are coking coals, and some are not, the exact reasons for which have not been determined. In burning coal, very great care is always taken to try and design a furnace suitable for the particular fuel to be burned in the plant. It has been learned by experience that this is necessary, and desiring to secure the best possible results, operators use all information available in order to improve their operating conditions. As regards sawmill refuse fuel, however, it has in general been customary to assume that a furnace with grates and surrounding brick walls or boiler heating surface suffices to make a good combustion chamber, and although this fuel has been used for the greatest number of years, certainly there is available less information as to its use in boiler plants than for any of the other fuels referred to hereinbefore.

A description of sawmill refuse fuel is desirable, particularly for those who, from close contact with the sawmills, may not be familiar with it and it is probable that the average man does not realize what a diverse class of fuel is referred to as sawmill refuse. Sawmill refuse fuel, as it is ordinarily termed, contains wood of every kind and size, from the finest dust from sanders to chunks and blocks of wood as large as probably a twelve-inch cube.

In general it is fortunate that the fuel is delivered somewhat in these diverse dimensions, in the ordinary plant, for they unquestionably would not be able to operate satisfactorily with either of the extreme sizes alone, and it is questionable whether a very satisfactory combustion could be secured with very fine sawdust alone, particularly if it be wet, in any type of furnace and this same applies in the case of fine coal. It is unquestionable that furnaces for sawmill refuse fuel should be designed for the fuel to be handled, and in general the two important elements to be considered are the shape of the fuel and the percentage of moisture in it. More recently, particularly in order to secure additional fuel, the mills have been putting slabs through a hog, thereby securing a fuel made up of chips of various sizes but of such shape as to burn readily and such shaped fuel is highly desirable in almost every plant burning mill refuse. The chips from a hog should average bits of wood approximately the size of one's finger, but when hog knives are dull frequently very much larger pieces go through. Of course the fuel is not round but is more particularly in flat chips. Of sawdust there are various sizes, from that from sanders, gang saws, band saws, and circular saws up to that which comes from shingle machines and from box board plants where the majority of the cuts are

Presented at the Pacific Coast Convention A. I. E. E., Portland, Ore., July 21-23, 1920.

with the grain of the wood resulting in sawdust which closely resembles excelsior. This latter also is a very desirable shape of fuel. From planers there are delivered shavings of various sizes and dimensions, the majority of which, however, are of a size to have an area less than that of a half dollar, and comparatively thin.

There is available as refuse from sawmills a great variety of woods. In some respects these woods are very similar but there is a great variation in some of their characteristics, particularly as regards the moisture content. The writer is giving below a list of the principal woods available in the different districts referred to and their approximate moisture content as ordinarily received as fuel from the sawmills:

CHARACTERISTICS OF PRINCIPAL SAWMILL REFUSE FUEL

Name of wood	Location	Percentage Moisture	Fuel Characteristic
Birch	Michigan	40 to 45	Fair burning
Cedar	Western Washington—Oregon and British Columbia	45 " 55	Fair
Cedar	Central California	40 " 50	"
Cypress	Florida, Texas, Mississippi	35 " 54	"
Fir	Washington —Oregon, British Columbia	35 " 45	Good
Fir	Central California	35 " 50	Poor
Hemlock	Washington, Oregon, British Columbia	40 " 50	"
Hemlock	Michigan	45 " 55	Poor burning
Maple	Michigan	40 " 45	Fair "
Pine-Cork	Eastern Washington—Idaho	35 " 45	Fair
" long-leaf	Florida and Gulf Coast	40 " 50	" burning
" Short "	" " " "	40 " 50	"
" " "	" " " "	20 " 40	"
" White	Mexico	45 " 55	"
" "	California	30 " 45	"
" Sugar	California	40 " 65	Poor
" Yellow	Central California	40 " 45	Fair
Redwood	California	45 " 50	Poor

It is interesting to note that dry non-resinous woods give off practically the same amount of heat in burning. This averages approximately 8500 B. t. u. per pound. From the above statement the reader should not be confused to the extent of assuming that the same volume of dry non-resinous woods give off the same amount of heat in burning. In order to make this perfectly clear the writer is pleased to give below a table secured from the United States Department of Agriculture Forestry Service showing the relative fuel value of non-resinous woods based on their specific gravities:

RELATIVE FUEL VALUE OF NON-RESINOUS WOODS BASED ON THEIR SPECIFIC GRAVITIES

	Specific Gravity (dry)	Relative Fuel Value per Unit Volume (dry wood)
Hickories, average	0.64	100
Oaks, average	0.58	91
Beech	0.56	89
Birch	0.55	87
Maple	0.55	87
Ash	0.52	81
Elm	0.52	81
Tamarack	0.49	76
Chestnut	0.42	65
Douglas Fir	0.42	65
Hemlock	0.39	61
Lodgepole Pine	0.37	58
White Pine	0.36	56
Redwood	0.35	55
White Fir	0.35	55
Spruces, average	0.33	52
Alpine Fir	0.31	48

The fuel value of woods varies considerably due to the amount of resin present. In general the woods ordinarily encountered in the Northwest territory do not contain large percentages of resin, however, some of them do contain certain percentages and consideration must be given to this in considering the fuel value of the refuse. Long-leaf pine encountered in Florida or the Southern Gulf Coast probably contains a larger percentage of resinous matter than any other woods in this country and the writer understands that in certain cases the resin content is as high as fifty per cent. As the calculated calorific value of resin is about two times that of wood, it is evident that the resin present has considerable influence on the heating value. Below is given a table compiled by the Forestry Service showing the relative fuel value of long-leaf pine containing different amounts of resin, and compared to hickory. In calculating the table the fuel value of resin as taken is 9400 calories per kilogram or approximately 16919 B. t. u. per pound:

APPROXIMATE RELATIVE FUEL VALUE OF LONG-LEAF PINE CONTAINING DIFFERENT AMOUNTS OF RESIN AND HICKORY

Resin Contents Per cent	Specific Gravity (dry)	Relative Fuel Value Unit Volumes of Dry Wood—Hickory 100
0	0.44	69
10	0.49	84
20	0.55	103
30	0.63	128
40	0.73	160
50	0.88	206

The other woods whose calorific value varies according to the amount of oil and resin they contain are short-leaf pine, loblolly pine, Western yellow pine, pinion pine, pitch pine, cedar, fir, juniper, cypress, etc.

It is interesting to note that non-resinous woods from an ultimate analysis are shown to contain about 50 per cent of carbon and the other parts principally hydrogen and oxygen in the proportions which burn to water. An analysis of woods most generally referred to is as follows:

ULTIMATE ANALYSIS OF WOOD

	Per cent Carbon	Per cent Hydrogen	Per cent Oxygen	Per cent Nitrogen	Per cent Ash	B. T. U. per lb.
Ash.....	49.18	6.27	43.91	0.07	0.57	-8,480
Beech...	49.06	6.11	44.17	0.09	0.57	8,591
Elm....	48.89	6.20	44.25	0.16	0.50	8,510
Oak.....	50.16	6.02	43.36	0.09	0.37	8,316
Fir......	50.36	5.92	43.39	0.05	0.28	9,063
Pine ...	50.31	6.20	43.08	0.04	0.37	9,153

There have been comparatively few ultimate analysis made of sawmill refuse fuels but the writer is pleased to include a few reports of analyses made which are particularly interesting because they are so scarce, though in general it will be noticed that they do not vary much from the analyses given hereinbefore. It is very difficult to make satisfactory ultimate analyses of wood samples and this is probably the reason why more have not been made.

ANALYSIS OF HOG FUEL SAMPLES

Sample No.	Per-cent mois-ture	Per-cent vola-tile	Per-cent fixed carbon	Per-cent ash	B. T. U. Per pound dry fuel	Per-cent carbon	Per-cent hy-drogen	Per-cent oxygen

1. Mixed refuse from Yosemite Lumber Co.
2. Average mixed fuel, Portland territory
3. Average fuel from manufacturing plant (using kiln dried material, Portland territory)
4. Average mixed fuel from lumber mill, Portland territory
5. Sawdust from first cut average fir log, Grays Harbor territory
6. Sawdust from heart clear fir logs, Grays Harbor territory
7. Mixed fuel from sawmill, Grays Harbor territory
8. Mixed Spruce refuse, Grays Harbor Territory.
9. Sawdust from clear spruce logs, Grays Harbor territory.

Sawmill refuse as we ordinarily secure it is seldom if ever segregated so as to contain but one class of fuel and particularly is this the case in the Northwest territory where the fuels are a mixture of various kinds of woods, the mills themselves cutting various kinds of logs, more or less as they happen to be delivered. The moisture content of the refuse is also a very variable item due to the fact that the refuse may come from not only the different kinds of woods but from different parts of the manufacturing plant where they may be handling very wet or kiln dried lumber. Then in addition a very large amount of moisture is added to the sawdust from some of the saws, particularly large band saws where water is kept running on the saw in order to keep it cool and assist in the cutting.

Quite a good many analyses have been made of the heat content of various samples of sawmill refuse fuel and the writer is pleased to give herewith a table showing some of these, with a memoranda indicating the source of the fuel as this is of the greatest interest and value. A few of these analyses were made for the Portland Railway and Light & Power Company by the Experimental Engineering Department of the Oregon Agricultural College, and by the Oregon Independent Testing Laboratory, Portland, Oregon, the rest of the analyses having in general been made by the Babcock & Wilcox Company.

The woods particularly considered in this article are those encountered on the Pacific Coast. The total amount of fuel available in this district is a matter very difficult of analysis but tests have seemed to indicate that approximately a total of one-half a unit of fuel is available per thousand board feet cut by a sawmill and as the total cut of the Pacific Coast, including Nevada, California, Oregon, Washington, and Idaho, during 1919 was approximately 9,250,-

000,000 board feet there should be available approximately 4,625,000,000 of units of mill refuse fuel per year. Certainly a considerable portion of this fuel is and will be used as slab wood and mill wood in the home. At present a larger amount of wood is used in this manner than is used in the industries outside of the sawmills themselves whose consumption of fuel it is difficult to judge.

The writer has referred to a unit of fuel and as the definition of a unit of fuel is frequently asked, an explanation at this time is in order. The writer believes that the Grays Harbor Railway & Light Company Plant at Aberdeen, Washington, was the first electrical generating station of material size designed to use sawmill refuse fuel. When the people operating the plant went out into the market to buy fuel it became necessary for them to arrive at some unit as the basis of a measure of fuel. Some experiments were made by putting a cord of slab wood through a hog and measuring the resulting fuel and although this seemed to indicate that approximately 177 cubic feet of hog fuel was the equivalent of a cord of wood before being put through the hog, there was established, the writer believes, by Mr. E. A. Bradner, the standard of 200 cubic feet as the measure of refuse and this was designated as a unit.

It is probably unfortunate that the unit has been established as a measure of sawmill refuse fuel as it is certainly not a good indication of the available heat units in such fuel. There is a very considerable variation in the weight of a unit of fuel due partly to the moisture content and partly to the settling of the fuel if it is allowed to stand for any length of time, particularly when subject to a superimposed load as is the case in high piles. No very accurate information is available to show just how much the fuel may settle but it is probable that there is a variation of a quarter or a third as a maximum from very loose fuel to that tightly compacted. Those who have had experience in piling sawmill refuse fuel in high piles or storing same in large fuel houses, realize how the fuel is compacted when they endeavor to remove the same, finding it so hard that it is frequently necessary to chop it out in order to remove it from the pile. It is practically impossible to remove it from the bottom of the pile while the load is carried overhead and it is necessary to remove the fuel by starting at the top and working down.

Certainly one of the reasons why mill refuse fuel has not been more extensively used is the difficulty of transporting and storing the same. The fuel is very bulky and on account of its characteristics is rather difficult to handle. It has only been very recently that this class of fuel has been transported any material distance and even now it is seldom that the fuel is moved more than a hundred miles on account of the high cost of transportation. The methods in use at the present time to transport the fuel consist in the main of barges, railway cars with special bodies and trucks. The latter are of course used only for comparatively short hauls. The difficulty is practically always in loading enough fuel into the transporting vehicle to give it an economical load. This condition is most nearly reached in the case of barges, and it is unquestionable that this is at the present time the best means of transporting the fuel, but of course the supply available where it can be loaded conveniently into barges and transported to the consuming plant is limited.

In general it is found that refuse fuel can be loaded quite conveniently if it is loaded directly from the mill and not run into previous storage. As long as the fuel is kept moving it is comparatively easy to handle, but when it is put into large piles or large storage bins then the question of handling it becomes a serious problem.

In the sawmills this class of material has in a great majority of cases been handled over chain conveyers; these are of various types but the principle is to scrape the fuel along a smooth trough from one point to another. The other principal means of moving it is by blowing the lighter fuels, such as planing mill shavings, etc., with fans and a strong blast of air from one point to another where the fuel is separated out from the air and deposited into bins or other conveyers. The sawmill men, having had a great deal of experience in handling this class of fuel, have, as is natural, hit upon a satisfactory means of moving it, and the writer knows of no more universally satisfactory means than the two referred to above; however, when large quantities of fuel have to be handled conveyers of this type become extremely heavy, expensive and hard to operate and in such installations it has been found that belt conveyers work admirably.

There are limitations to the use of belt conveyers. It is the writer's opinion that they should not be used with wide boards, and narrow belts are unsatisfactory because so much of the fuel is lost over the side. Then again it is not very satisfactory to unload the belt at more than one point unless a tripper is used, which is a piece of apparatus so expensive that its use is not warranted in small plants. There is a question as to whether belt conveyers should be troughed or flat, the writer prefers and sees no serious objection to the troughed belt and he would recommend it.

There is no use in this article to describe conveyers, particularly chain conveyers, which are of numerous designs and are in general well-known. The type of conveyer for any particular plant depends upon the fuel to be handled, and the service required. The writer has already spoken briefly of the storing of this class of fuel and has stated that it is easy to store the fuel but very difficult to get the fuel out of storage. In sawmill plants it has been the custom to store the fuel in fuel houses at which point there is collected all of the various kinds of refuse that come from the mill,

excepting of course the larger sticks and pieces which are usually burned up in a refuse burner. Such storing of the fuel is quite satisfactory where large quantities do not have to be handled but experience has indicated that a great deal of difficulty is experienced in removing this fuel from large fuel storage bins. In such containers when the fuel is allowed to stand for a time it settles down into a very compact mass and some mechanical means should always be had for loosening the fuel up on the surface and gradually working it down from the top.

On account of the difficulty of storing the fuel in houses large quantities have recently been stored in the open and later reclaimed for fuel use. The two largest storages at present consist of the one at Station "L" of the Portland Railway Light and Power Company and at the plant of the Northwestern Electric Company, both at Portland, Oregon. It is really not very expensive to store fuel in this manner if ground space is not too valuable. The fuel is moved with specially designed rakes and in a well designed installation but little labor is necessary.

There has been a great deal of discussion as to the possible fire hazard in storing large quantities of this fuel either in fuel houses or out in the open. Some years ago, the writer being particularly interested in the subject, investigations were made and the Forestry Bureau was appealed to for information as well as the fire insurance companies. No record was had of any fire having started in a fuel house or in a pile of fuel due to spontaneous combustion and but few fires have occurred which have destroyed fuel houses. When piled up in a large mass this fuel is very hard to burn and can be burned from the surface only, so that severe conflagrations are not at all likely, as a matter of fact it is very difficult to get the fuel to burn when in large piles even in furnaces. It is the writer's belief that there is very little fire hazard indeed from storing this fuel as it is ordinarily received. Very dry sawdust and shavings from kiln dried lumber might cause difficulty if they alone were stored in large quantities but this condition is practically never encountered.

There is unquestionably some depreciation in the fuel value of mill refuse when stored, particularly in the open for a material length of time. The writer is very much of the opinion that this amounts to but little under ordinary circumstances. He has heard of one or two instances where fuel of this kind has been recovered after years of lying out in the open and with its use satisfactory steaming of the boilers was secured. At least one sample of fuel having been stored eight months in the open was analyzed by the Portland Railway Light & Power Company which seemed to indicate that there was a large increase in the moisture content of the fuel, some slight increase in the amount of ash and a little falling off in the B. t. u. per pound dry fuel, doubtless due to the ash present. The writer is not certain as to just how this sample was selected but it is certainly not always the case that in storing fuel the moisture content is increased as certainly in many cases the fuel is dried out somewhat as lumber is air dried. In drying out in this manner a certain portion of the water is quickly given off, particularly if atmospheric conditions are at all favorable. The evaporation then slows up very suddenly and a considerable amount of moisture is always retained.

The type of furnace for sawmill refuse fuel is a matter that should receive most careful attention. The writer has tried to explain hereinbefore that sawmill refuse fuel is of very diverse types and a consideration of the particular fuel to be burned should determine in a large measure the design of the furnace.

There are, however, a few fundamental features in the design of the furnace which from analyses and from experience evidently are correct. Although it is quite probable that as good or possibly better efficiencies could be secured with hand firing, the great majority of installations feed the fuel to the furnace in a more or less continuous stream, the fuel being delivered through a hole in the top of the furnace to pile up in a cone on the grates. This method of firing is much the most simple and economical from a labor standpoint, one man being able to take care of several thousand horse power of boilers in a properly designed plant.

Considering fuel to be delivered to the furnace in continuous manner referred to above, then one can readily see that in order to expose the greatest possible amount of surface of the cone for burning and yet to prevent excessive infiltration of air through the grates each fuel pile should cover practically a square section of grate. Experience has indicated also that this is essential for the best operating conditions. If additional grate surface is desired in front of a boiler then the furnace can be so designed that there will be two fuel piles per furnace, piles being arranged in tandem, the grates then being pratically twice as long as they are wide.

The writer is of the opinion that a furnace approximately six feet wide is ideal but in many installations it is impossible to secure ideal conditions and therefore furnaces have to be designed, many of them operating entirely satisfactorily, which vary widely from the width specified above. It is very probable that a reduction in the width of the furnace is more serious than an increase in the width of the furnace from the figure referred to and as a matter of fact it is quite possible, and many satisfactory installations have been made, where furnaces are as much as 12 feet wide but in such cases the grates are covered by at least two fuel holes across the width of the furnace. There are some structural difficulties in making a furnace wide, as that of the support of the fire brick arch, which should be over the top of the grates.

Experience has indicated that with any type of

fuel furnace temperatures can be varied by changing the area through the throat of the furnace. Any tendency to bottle up the furnace results in a material increase in furnace temperatures. High temperatures are desirable for burning ordinary sawmill refuse and this bottling effect can and is secured most advantageously by running the bridge wall up to such a point as will give the desired temperatures without interfering materially with the draft. The furnace should be surrounded on the top and sides with incandescent fire brick. The reflected heat aids in the combustion of the fuel and the distillation of the moisture present.

The area through the throat of the furnace referred to above is a variable quantity and shouldbe figured out carefully for the installation. The writer cannot give a detailed analysis of this particular feature but in general will state that the area through the throat of the furnace should be from 6 to 14 square inches per rated boiler horse power, depending upon fuel conditions, design of furnace, the rating which is to be expected, and the available draft.

The question of the proper admission of air to the furnace is a matter of considerable importance. As the combustion is mostly on the surface of the cones of fuel the air should be available at these points. It is undesirable to have excess air with this class of fuel as with any other. In some installations it has been found desirable to keep the fuel holes at the top of the furnace open for the admission of air and in other installations far better results are secured by closing these up by one means or another. As with almost every class of fuel slight adjustments are necessary after the plant is put into operation; the writer believes that this particular point of the admission of air through the fuel holes is one that should receive special consideration at that time and there is no very good way of telling before hand just what to expect.

The analyses of this class of fuel that have been made indicate that it contains a very large percentage of volatile. It can readily be understood that this will be quickly distilled off in a hot furnace and in addition much of the finer fuel is quickly carried with the force of the draft out of the furnace. These conditions make it highly desirable that the installation be provided with a combustion space back of the furnace and before the heating surface of the boiler is reached, in order that this unconsumed fuel can have an opportunity to burn before it reaches the heating surface of the boiler. In this combustion space there should be tuyeres and a door or damper to control the admission of air to them. In this manner supplementary air is added at this point and combustion conditions are materially improved. In general the most convenient place for the admission of this secondary air for combustion is through the bridge wall. Experiments have indicated that the most satisfactory place for admitting the air is either on the top of the bridge wall or on the back face of it. On the top of the bridge wall the air can be admitted through grate bars and on the back face of the bridge wall through openings made by leaving out a brick now and then. The difficulty with the opening on the top of the bridge wall is that it may become clogged with soot or ash and it permits this matter to sift down into the space below.

Under any circumstances, for the most efficient conditions, the arch of the furnace should extend beyond the point where the supplementary air is admitted as this arrangement brings the gases and the air most intimately in contact with each other.

The height of the arch above the grate is a factor depending upon the width of the furnace and the kind of fuel to be handled. The height of the arch determines in a great measure how hot the arch will be. Experiments have indicated that a change in the height of the arch of a foot or even less will change the temperature of the arch so much that the effect upon combustion is very marked. In general the arch is approximately five to seven feet above the surface of the grates. In a wide furnace it will, of course, be necessary to have two fuel holes across the width of the furnace in order to cover the grates from this height. The crown of the arch is a matter for an engineering design and cannot be covered at this time.

There are as many different designs of grates for sawmill refuse as there are colors in the rainbow. It is the writer's opinion that the simpler grates are much the best, either the straight bar or the herring bone. It is desirable to secure a grate with as large a percentage of air space as possible and yet have the bar strong enough to stand up under the rather severe conditions encountered with this fuel. The writer believes that the smaller bars are preferable due to the fact that in overheating they will not warp so far out of line as a longer bar and it is less expensive to replace them. The width of air opening in the grate is very important and depends upon the class of fuel to be handled. Where there is a great deal of fine sawdust of course the width of air space should be less. With coarser fuels the width can be increased. It seems that practically always there is a certain amount of fuel that falls through the grates and this should be prevented as far as possible. Experience has seemed to indicate that the width of the air space should not be more than one-half in. and in a great majority of cases less than this. The writer has never seen any experiments made with sawmill refuse fuel on shaking grates but on account of the very large percentage of air space (35 per cent or more) which can be secured with this type of grate and with an air opening not to exceed one quarter in. we believe that this grate in a properly designed installation would readily pay for itself. It would be particularly easy to keep such a grate clean. Ordinarily there is a certain amount of dirt fed into the furnace with sawmill refuse which clings to the bark of trees, etc., which collects

on the grate surface and periodically has to be removed.

In the majority of plants the ash pit below the grate is comparatively shallow, and the fuel which sifts through the grates, on account of the high temperature, readily burns and great difficulty is experienced in making grate bars and bearers stand up under these severe conditions. Practically all installations are provided with some means or other for flooding the ash pit or quenching fire in the ash pit with a hose or other means of that kind. Water in the ash pits unquestionably helps to keep the grates cool and adds to their life.

There are two schemes which the writer would like to recommend as offering a better solution of this difficulty, they are not original but are seldom used—one is to have a means of washing the cinder from the ash pit in a trough either carrying running water or provided with a means of turning water into it for flushing purposes and the other is to make the installation with a considerable distance between the grates and the bottom of the ash pit so that the grates will be kept cool. In practically every installation either one or the other or both of these schemes would be well worth the investment.

Experience with sawmill refuse fuel has seemed to indicate that logs which are transported in salt water pick up an amount of salts which makes the fuel from such logs harder on brick work in furnace settings. It seems quite probable that sawmill refuse under any circumstances contains certain chemical elements which make the action on brick work different from that of other class of fuel. Where one particular brand of brick would work out with oil it might not do so well with mill refuse. The writer mentions these items at this time due to the fact that we have not on the Pacific Coast as good quality of fire brick as can be secured in the Eastern states, and we always experience more or less difficulty here with our refractories. Experience is the best guide as to the type of brick to be used. In laying up a furnace for this class of fuel, as for any other, an item that has the greatest bearing upon the stability of the installation is the workmanship and the writer would like to see better brick work jobs than we are accustomed to getting in this territory. Where fire brick are laid close together and fitted with care the flames do not have much opportunity to get between the fire brick, but a well laid up job with mediocre brick will probably out-last a poor installation of good brick.

The writer has assumed the average ultimate analysis of fir wood as follows:

C	50.36
H_2	5.92
O_2	43.39
N	0.05
Ash	0.28

and from this analysis has figured the amount of air theoretically required for combustion; the total weight of the products of combustion with various percentages of excess air; the percentage by weight of the various products of combustion with different percentages excess air; and the percentage by volume of the different products of combustion with varying percentages excess air. The table of these values is given herein and from these results has been plotted a curve which indicates for the analyses as assumed, complete information within the range covered.

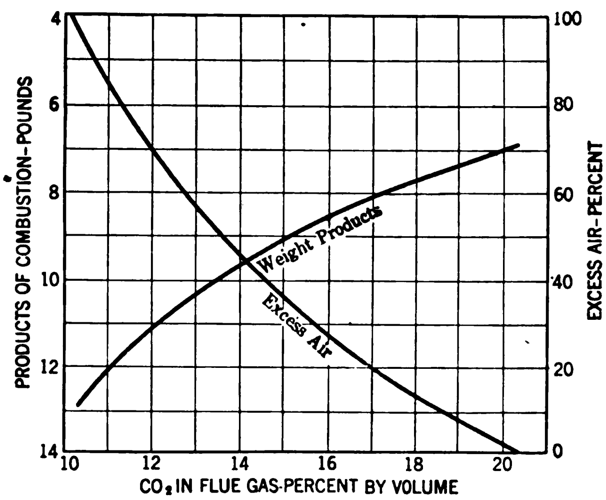
It is probable that the average analysis of sawmill refuse fuel on the Pacific Coast does not vary much from the wood analysis which has been used and it is probable that the results indicated are approximately correct for average conditions. Where analyses of flue gases can be made, comparison with this curve will give

an approximate indication of the combustion which is being secured.



It has been customary and seems to be quite satisfactory to figure stack capacities for sawmill refuse fuel on the same basis that we figure stacks for coal fuel. We can probably figure a little less stack area for sawmill refuse fuel than is figured for the standard tables of stack sizes for coal fuel. However, sufficient information has not been secured as yet so that a definite figure can be given. On the other hand with the average installation the owner is always desirous of getting large overload capacities out of his installation and to assist in this it is desirable to have tall chimneys. When one realizes that the capacity of an installation is dependent in a large measure upon the stack capacity it is readily realized that a little bit of additional money spent for a larger chimney is well invested.

In the average sawmill plant at least one or more boilers are shut down over the week end for washing out. Where steel stacks are used there is a distinct advantage of having one stack for a battery of two boilers, due in large measure to the fact that with such an installation it is always possible to keep one boiler of the battery in operation over the week end and keep the stack hot and prevent in a certain measure the corroding action which seems to be quite marked in steel stacks where sawmill refuse is used.

It is unfortunate that complete information from various sources is not available to indicate efficiencies of boilers and furnaces when using sawmill refuse fuel. We believe that the most complete tests that have been made so far have been in the plant of the Portland Railway Light & Power Company, Portland, Oregon. The writer is indebted to the courtesies of the management of this concern and to the personal assistance of Mr. H. S. Bastian, Assistant Engineer, for the very complete set of tests, reports of which follow. In giving the results as indicated by these tests, the writer wishes to call attention to the fact that the tests were made to try to provide the best type of furnace construction for the boilers at the plant. This means that they were not entirely at liberty to change the furnace design in order to secure the best possible arrangement but had to be limited largely with space available.

These tests are particularly interesting in view of the fact that very complete analyses of fuel were made from liberal samples taken during each test and all measurements were carefully taken in order to assure accurate results being secured.

It might be interesting to indicate briefly the general changes in furnace design that were made at the time the tests given in the following Table were run.

Test No. 1 was made with the boiler and furnace as found.

Test No. 2 was made with the same boiler and furnace as Test No. 1. but here hand firing was resorted to in an endeavor to show that by so doing better results could be secured from an economical standpoint than by firing through fuel-holes as was done in the first test.

In test No. 5 the same general furnace arrangement was used as in the two previous tests but a single fuel hole was used instead of two in parallel.

Test No. 6 was made on a Babcock & Wilcox Cross Drum boiler with a Riley stoker. Three feed chutes fed supplementary fuel through the front of the furnace.

Before Test No. 7 the bridge wall construction was changed and a curtain wall or hanging arch was provided almost directly above the bridge wall. There was a marked decrease in the amount of cinders discharged from the boiler during the test.

Test No. 8 was run with the general construction of furnace as in Test No. 7 except that four fuel holes were used to feed the furnace rather than one. Before this test the grate area was reduced from that in previous test by taking out some of the grates at the back of the furnace. During this test but two of the front firing holes were used.

In Test No. 10 especially dry fuel was used. The general furnace arrangement was as in previous test.

Test No. 12 was made on boiler No. 6 at Station L of the Portland Railway Light & Power Company plant. The grates were eight feet long. The front portion of the grates being about 6 feet 5 inches below the crown of the arch and in the rear about 7 ft. 10 in. The grates were therefore considerably lower, approximately 1 ft. 1½ in., than the grates in boiler No. 3.

In Test No. 13 boiler No. 7 at Station L was used. Grates were 7 ft. 2 in. long by 12 ft. 2 in. wide. Two fuel holes covered the width of the grates. Secondary air for combustion was admitted through grates placed at the top of the hollow bridge wall.

The writer wishes to call attention to the fact that efficiencies given in report of tests, based upon available heat in fuel are determined from the total heat per pound dry fuel by calculating the available heat per pound of fuel, assuming 600 degrees stack temperatures and 60 degrees temperature in fuel as fired.

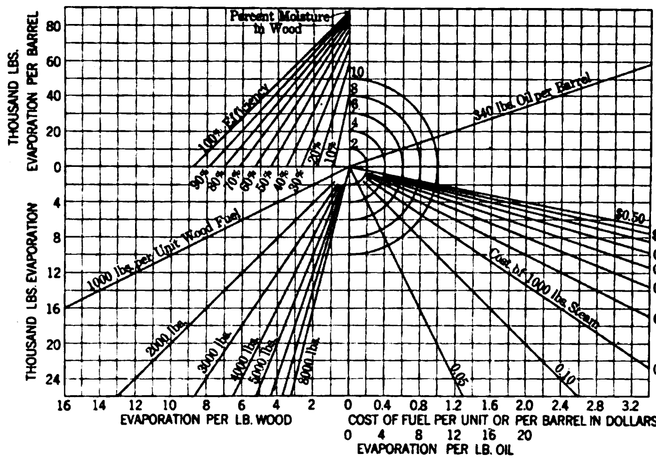
In addition to the above tests the writer is permitted to publish some tests made by the Babcock & Wilcox Company at the C. A. Smith Lumber Company plant, Marshfield, Oregon. During these tests as during the majority of tests with sawmill refuse fuels, no effort was made to determine the efficiency of combustion of the fuel and absorption of heat by boiler. The effort was to secure good combustion and determine the capacity at which the boilers were operating with the fuel available. These tests were made on Stirling boilers provided with extension furnaces or what is commonly termed the Dutch Oven setting, and each furnace was provided with two fuel holes placed in tandem in order to cover the grate area. Each boiler had two furnaces and each furnace was approximately five feet wide. The tests indicate very satisfactory combustion conditions when one notes the capacity secured from the boilers.

A great many tests have been made by the Babcock and Wilcox Company in order to determine the best possible furnace arrangement for various classes of sawmill refuse fuels and to determine the capacities that could be secured with boilers with these different fuels. As most of these tests were made in sawmill plants where fuel was of no particular value, economic results were not determined. It would, therefore, be of no particular value to repeat at length such tests at this time as they do not indicate results materially different from those already given.

It will be noted that considerable information in reference to the use of sawmill refuse fuel is yet to be secured. It would seem that we had not reached efficiencies as high as are possible, but as it is very expensive to make accurate tests, it is probable that little testing work will be done until such time as extensive purchasing of this class of fuel may make it necessary to secure more complete data.

The majority of the power plants on the Pacific Coast at the present time are using oil fuel and in order to indicate the comparative results that might be expected with sawmill refuse and oil fuel the writer has made up a set of curves for this purpose. On the sheet is indicated the assumptions that have been made and as the B. t. u. value of dry wood is quite uniform it is probable that the assumptions are not greatly in variance with the average conditions.

It is to be noted that the evaporation per pound of wood as shown by the curves is based upon the available heat in the wood as calculated. There are various ways of stating efficiencies and this particular matter should not be confused. Efficiencies can be stated on the basis of the total heat per pound of fuel as determined by a calorimeter; based upon the total heat of a pound of dry wood as determined by a calorimeter; based upon a pound of combustible; based upon the available heat as shown by a calorimeter or based upon available heat as calculated from the total heat of a pound of dry wood. This latter method is quite satisfactory and we believe applicable in the majority of cases, as was the case in the tests of the Portland Railway Light and Power Company.



Wood and Oil Fuel—Curve of Comparative Values
Assumptions: 8500 B. t. u. per lb. dry wood
200 cu. ft. = 1 unit
550° Stack temp.
60° Wood fuel temp.
Evaporations from and at 212 deg. fahr.

As an explanation of the use of the curve we can assume the following conditions and follow through a determination. Oil $1.00 a barrel, 12 lb. evaporation per pound of oil. Sawmill refuse fuel containing 45 per cent moisture, weighing 20 lb. per cubic foot efficiency 60 per cent. The problem is to determine what can be paid for sawmill refuse fuel per unit to equal the fuel value of oil at the price stated.

Starting with the value of 12 lb. of evaporation per pound of oil, directly above this at the point of intersection with the line indicating the pound of oil per barrel we note that on the left the total evaporation per barrel of oil is 4080 pounds. Transferring this below the line as indicated by the semicircle and carrying 4080 lb. evaporation across to the right we note that under the figure $1.00 per barrel, the cost of one thousand pounds of steam is about twenty-four and one-half cents.

Starting again with 45 per cent moisture in the sawmill fuel and going to the left to the point of intersection of 60 per cent efficiency we note that the evaporation per pound of wood is approximately 2.3 lb. water, or with 4000 lb. per unit this is equivalent to about 9200 lb. of water per unit of fuel. Carrying this to the right to the point of intersection with the line indicating cost of steam twenty-four and one-half cents per thousand pounds, we note $2.25 as the equivalent cost of a unit of fuel.

On the same basis if oil cost $2.00 a barrel the equivalent cost of sawmill refuse would be twice the above or $4.50 a unit. In this manner a ready reference is secured and the curve can probably be read far more accurately than will be the assumptions made.

There has not been a very extensive use of sawmill-refuse fuel in power plants, up to the present time, due

to the fuel being so bulky and inconvenient for handling in large quantities, and also because other fuels have been available at prices which make them more attractive. However, recent heavy advances in the cost of coal and oil have driven a few concerns to the use of sawmill refuse. Besides the other large consumers referred to in this article attention is called to the fact that quite a number of small users are now relying upon sawmill refuse which is delivered to them in trucks. Such plants are laundries and the like where the boilers installations are not large. The writer is advised that some ofthese plants are getting their fuel at a very low cost indeed. There is no reason why this class of fuel cannot be used more extensively by such people where reasonable continuous delivery of fuel can be secured.

It is interesting to note that the Portland Railway Light & Power Company has secured very satisfactory results with the use of sawmill refuse fuel on Riley stokers. The fuel fed through the retorts of the stoker is supplemented with additional fuel fed from overhead chutes. Although one can readily understand that the installation of stokers for sawmill refuse fuel would not be warranted, nevertheless, that this class of fuel can be burned on a stoker with satisfactory results makes it possible to shift quickly from coal to mill refuse or back again as the case may require. The Babcock & Wilcox Company, before the war, had prepared an installation of Stirling boilers with Jones stokers for the Washington Pulp & Paper Company, Port Angeles, Washington, which installation was not completed on account of the war.

On account of the recent curtailment in the supplying of oil for fuel purposes it is quite probable that we shall soon see a much more extensive use of sawmill refuse. The writer would be pleased to see stopped the tremendous wasting of materials so satisfactory for fuel purposes, which has continued for so many years.

Pulverized Coal as a Power Plant Fuel

A great deal has been written for and against the use of pulverized coal as a power plant fuel, therefore, a few statements regarding reasons for its utilization as well as citations of some of the installations which are operating successfully will be more convincing as to its merits than a lengthy discussion of its theoretically good qualities.

One of the best reasons for pulverizing coal is that it permits of the utilization of all kinds and sizes of coal with approximately equally good efficiency, whereas, with either hand-fired or stoker-fired boilers the efficiency varies greatly with the quality and size of the coal used. The standard degree of fineness for pulverizing coal for boiler use is 95 per cent through a 100 mesh sieve and 85 per cent through a 200 mesh seive. With this fineness the surface exposed is increased on an average seven or eight hundred times and it is possible to obtain a perfect mixture of these particles with air for combustion.

The northwest territory contains large quantities of low-grade coal and consequently has been and undoubtedly will be a good field for the general use of pulverized coal. The first successful installations in this territory were made by the Pacific Coast Coal Company, of Seattle, Washington. This company now having three pulverized coal plants. One of these, a five ton per hour plant is located at its Black Diamond Mine, Black Diamond, Washington. A subbituminous coal mined at Newcastle, Washington, is shipped to this plant, dried and pulverized and burned under 250 h.p. vertical water tube Wicks' boilers and nine 125 h.p. return tubular boilers. This coal is a very fine buckwheat, all of which passes a 3/16-inch screen and before the advent of pulverized coal was not marketable and had been wasted down a creek and deposited in Lake Washington. During the past winter part of this coal has been reclaimed, some of it being used in this plant and some sold for use in a pulverized coal plant in Seattle.

Another five ton per hour plant is located at Newcastle, Washington, where the coal mined is used under eight 125 h.p. Horizontal Return Tubular Boilers. Both of these plants are so constructed that it requires only one man to operate the machinery. The driers are fired with pulverized coal and all the machinery is driven by one steam engine through belts and line shafting.

The other installation of this company is a nine ton per hour plant built in connection with their Briquet Plant at Renton, Washington, fourteen miles distant from Seattle. This plant is used as a central plant from which delivery is made by railroad cars and auto trucks to small boiler plants in Seattle. The pulverized coal is loaded by a screw conveyer from the mills into a specially designed railroad car and transported into Seattle, where it is stored in an 80-ton bin which is constructed so that the pulverized coal can be fed out by gravity into auto trucks built to haul five tons a load to the various consumers. The coal is unloaded from the trucks by gravity through dust-tight connections into the consumer's bin located in or adjacent to the boiler room.

The following named installations have been made in Seattle:

The Seattle Natitorium	two 100-h.p. horizontal return tubular boilers
The New Richmond Hotel	one 75-h.p. dry back Scotch marine boiler and one 50-h.p. dry back Scotch Marine Boiler.
L. C. Smith Building	one 300- and one 200- h.p. B. & W. water tube boilers
The Broadway High School	three 125-h.p. horizontal return tubular boilers
Independent Laundry	one 85-h.p. horizontal return tubular boilers

The installation in the L. C. Smith Building has brought forth considerable favorable comment, due to its simplicity and neatness, as well as the central location of the building and its fame as a 42-story building.

The above mentioned commercial installations are unique in that the powdered-coal storage bins are located some distance from the boilers and not in the same rooms. This was done to conserve valuable space in the boiler rooms and in some instances to facilitate delivery from tank trucks. The pulverized-coal feeders are located beneath these bins and are driven either by friction or variable speed motors and in either case the controls are located in the boiler rooms. Primary air pressures, varying from one and a half to three pounds, are used for mixing and conveying the coal to the boiler furnaces, this pressure depending upon the distance and number of bends in pipe lines. This air is admitted at the feeders, induces with it additional air for combustion and transports the pulverized coal through pipes laid beneath the floor to the boiler furnaces. These pipe lines are so equipped with gates and valves that any or all of the boilers may be fed from any part of the storage bins. These storage bins vary in capacity from six to twenty-five tons, the larger ones being built of concrete and the smaller ones of steel. The boilers of all of these installations were formerly fired with oil and due to low boiler settings it was practically impossible to enlarge furnaces, and outside of removing the grates no changes were made in them. Nevertheless the operation of these boilers has been quite satisfactory, undoubtedly due to the fact that in all but one of the installations boilers are operated at not more than their rated capacity though in this one case, boilers have been operated at from 150 to 200 per cent rating, but not for more than a six-hour period.

The Puget Sound Power & Light Company formerly used fuel oil in their Western Ave. Steam Heat plant, but during the first part of 1917 at the time the price of oil was advancing and oil companies were refusing to contract for future deliveries on account of war conditions, they decided to run some tests on pulverized coal because they desired to determine what fuel could be best used to displace the oil. Coal for these tests was dried and pulverized at the Briquet Plant of the Pacific Coal Company, at Renton, Washington, and transported to their plant in a specially constructed railroad car. All the various kinds of coals, including lignites, sub-bituminous and bituminous mined in the vicinity of Seattle were tried out and it was demonstrated that approximately equally good efficiencies were obtained with all these coals.

As a result of these tests this company started the erection of a pulverized coal plant and the equipping of 4100 h.p. of Babcock & Wilcox water tube boilers with pulverized-coal burning equipment. This plant was completed in 1918 and has been operating since that time. The greater amount of coal used in this plant is a washery sludge coal from this company's mine at Renton, Washington. This sludge coal is of a very fine size, about 50 per cent will pass a ten-mesh seive. This size renders it totally unfit for use in any existing form of mechanical stoker. About 200,000 tons of this coal have accumulated during the past fifteen years. By analysis it runs 20 per cent moisture, 25 per cent ash, and about 7500 B. t. u. per pound. This coal is very difficult to handle to conveyers and driers, but nevertheless it has proved, when pulverized, to be an efficient fuel, so that this plant has provided a way of utilizing the coal that heretofore has been worthless and even an expense, as it was necessary to provide a place for its storage. It is interesting to note that the average evaporation at this plant is about five pounds water from and at 212 degrees Fahrenheit per pound coal as received. Test results indicate an evaporation even better than nine pounds per pound dry coal Issaquah screenings containing 11,400 B. t. u. per pound.

The other large boiler installation in the Northwest using pulverized coal is the one located at Vancouver, British Columbia and owned by the British Columbia Sugar Refining Co. This plant is using a coal from Vancouver Island, which runs between 25 and 30 per cent ash but has given very good boiler efficiencies during the fourteen months of the plant's operation. With Nanaimo bituminous slack this plant on test has had about eight pounds evaporation per pound dry coal containing 9364 B. t. u. per pound. Complete reports of these tests have previously been published and need not be repeated here.

Other concerns using pulverized coal in this section are three cement companies, which are using a sub-bituminous coal of quite high moisture and ash content and also the Tacoma Smelter, where the pulverized coal is fired in a reverberatory furnace used for smelting copper ore. This furnace is provided with two 500-h.p. Stirling waste heat boilers, which develop about 1000 h.p. with an evaporation of five pounds of water per pound of coal fired to the furnace. This is being accomplished with a coal of 11,000-B. t. u. value.

In this Northwest territory there are large deposits of low-grade lignite and sub-bituminous coal yet to be developed, whereas, practically all of the fields of better grades of coal have been developed and operated for a considerable time and the estimated life of these properties is fairly short. So it is reasonable to suppose that the source of fuel supply for this territory will in the future have to be from the poorer grades of coal, and as the attempts to burn these coals with mechanical stokers and by means of gas producers has been unsatisfactory, pulverized coal will undoubtedly become more generally used.

The utilization of the poor grades of coal by pulverizing is not confined entirely to the Northwest territory. In the anthracite fields of Pennsylvania the old culm piles are being used in this way. The N. A.

Hanna Company, at Lytle, and the Susquehanna Collieries at Lykens have made installations at their boiler plants and have been obtaining very high efficiencies and general good results.

The writer understands that order has recently been placed by the Milwaukee Electric Railway & Light Company, Milwaukee, Wisconsin, for powdered coal burning equipment for a new 40,000-kw. station to contain eight 1308-h. p. boilers to be operated at 250 per cent of their rated capacity continuously. This same company has at present in operation five 468-h. p. boilers which installation was operated so successfully that the new plant will be equipped with similar coal-burning machinery.

The Bethlehem Steel Company has just recently put into operation a plant containing four 500-h. p. boilers with furnaces designed for powdered coal to operate continuously at 150 per cent of rated capacity of the boilers. The coal at present being burned is pumped from the Susquehanna River; it is an anthracite coal and a notable feature of the installation is the type of burner which throws a fan-shaped flame vertically downward. This arrangement seems to permit the heat to penetrate the flame very rapidly and very quick ignition of the fuel is secured. The boilers are operated with induced draft fans and back of each boiler is a Green economizer, and the installation has proved so satisfactory that this same company is contemplating the installation of pulverized coal for all of its boilers in this power house at Lebanon as soon as it is able to secure the pulverizing equipment. This same company has been using pulverized coal for certain parts of its work for approximately fifteen years and is therefore very familiar with its general operation.

The writer also understands that Mr. W. B. Uihlein of Milwaukee, Wisconsin, is installing a plant in connection with a food produce manufacturing establishment to contain four 500-h. p. boilers designed to operate at 200 per cent rating.

It is of course not necessary that a poor grade of coal be used in a pulverized coal installation; the better coals will evaporate more water per pound or per ton and are therefore more desirable.

A great deal has been said about the difficulty with ash and fine dust coming from the stack of a powdered coal installation. The amount of this ash seems to depend in considerable measure upon the kind of coal being burned, and the quality of the ash. If the ash is very fine and light it is easily carried out of the boiler setting with the force of the draft, in other cases the ash may be heavy enough to deposit in the boiler setting or in settling chambers provided for that purpose. It seems that it is very desirable where a plant is installed in a thickly settled district to provide some means of taking care of this ash. A very tall chimney will of course distribute ash in smaller quantities over a wider distributed area and this may suffice in the majority of installations, however, there is a certain amount of ash which comes out of any stack burning powdered coal and the time may come when it will be necessary to take care of this.

In the city of Seattle where powdered coal plants are in operation in the heart of the city, we believe that there has been no recent complaint on account of the ash, however, it is quite evident that some ash is being scattered around and the greater use of powdered coal might cause this to become such a nuisance as to call for legislation.

On account of the ability to light powdered coal quickly, to put it out quickly, and to carry heavy overloads quickly where necessary, it seems probable that this fuel will find a field of usefulness not only in order to take care of poorer grades of coal but also in stand-by plants where the above features are of very considerable importance.

It is interesting to note that the Pacific Coast Coal Company recently fired some powdered coal which had been in storage for almost a year and found that it worked very satisfactorily. They had no difficulty in keeping the coal in storage for this length of time, as being perfectly dry there was no evidence of overheating.

Since practically all tests of powdered coal installations have been published and as there are no recent tests in the Northwest territory which have not been published, the writer is not endeavoring to restate these here.

Fuel Oil

There has recently been a great deal in the papers and a considerable discussion about the probable shortage of fuel oil in the near future, and it is certainly a fact that a number of users have been notified that they will have to rely upon some fuel other than oil to carry their load. The writer believes that none of the oil companies are writing any new contracts at the present time. However, it is very probable that oil fuel will be used for many years to come, and although a great deal has already been written about oil, nevertheless, some features of its use which are being developed from time to time will be interesting to those who are fortunate enough to have this fuel available for their use.

It is the understanding that the production of oil last year was the largest in the history of the production of crude oil in the United States, and totaled over a million barrels of oil per day. The present apparent effort on the part of the oil companies to curtail the use of this fuel is evidently on account of the depletion of their reserves. At the beginning of 1918, there were approximately one hundred and forty million barrels of oil in storage; at the end of 1918 in the United States there were probably not more than about one hundred and twenty million barrels, and at the end of 1919 there were about one hundred and twenty five million barrels in storage in the United States. Although there has been a slight gain in the amount of oil in storage during

the last year this is still not back to the normal pre-war amount. The writer understands further that the storage accumulated during the winter is depleted during the summer months, and there is threatened to be a really severe shortage this present summer.

There has been published some information in periodicals to indicate that at the present rate of consumption the available fuel oil in the United States will be used up in about twenty years. The writer questions this very much and of course the present rate of production will probably not be kept up. It also seems probable that other sources of supply of oil will be discovered to increase the present known oil-producing districts. However, it does seem probable that there is going to be an increase in the cost of fuel oil, which may be so marked as to make it necessary for us to confine the use of this fuel to certain installations where it is particularly advantageous or in standby plants where it is an ideal fuel.

The writer wishes at this time to call particular attention to the use of fuel oil in standby plants. There has been so much information published in connection with the general use of fuel oil that reports of tests of the ordinary kind at this time would add little to the information which we all have. Ability to get up steam in a cold boiler in 30 minutes and to be operating the boiler at 200 per cent of rating or more in a very few minutes thereafter makes this fuel ideal for emergencies in standby plants.

In considering the use of oil fuel in standby stations, where it is frequently necessary to carry heavy overloads, it is desirable to secure as high evaporative efficiencies as is possible at these heavy overloads. Records of tests with oil fuel have in general indicated a considerable falling off in efficiency as soon as the boiler was operating at a little above its rated capacity. This is a condition which is to be expected and applies to any fuel, but experiments have been made with apparent success to indicate that we can secure better efficiency at overloads than we have been accustomed to getting in the past.

Through the courtesy of the Babcock & Wilcox Company the writer is permitted to publish some tests made at the Bayonne Works of the Babcock & Wilcox Company on a Babcock and Wilcox boiler, with a mechanically atomizing oil burner of the Lodi type, which is the latest development in oil burners by that company.

The results of the tests of the mechanical oil burners are shown in the table which is so marked. The average results are indicated by a curve shown in Fig. 1 which, also shows a curve for the net efficiencies obtainable with steam atomizing burners. By net efficiency is meant the efficiency based on the total steam evaporated less the steam blown to waste in atomizing the oil.

Fig. 2 shows a Lodi burner, the parts being numbered and the functions of the parts being indicated thereon.

There are a few features of particular importance brought out by these tests. It will be noted that the efficiencies are well maintained even at very heavy overloads. The other remarkable feature is that in a very restricted furnace volume enormous quantities of oil were burned and even at the high percentages of rating the combustion, as indicated by the flue gases analysis, was maintained very uniform.

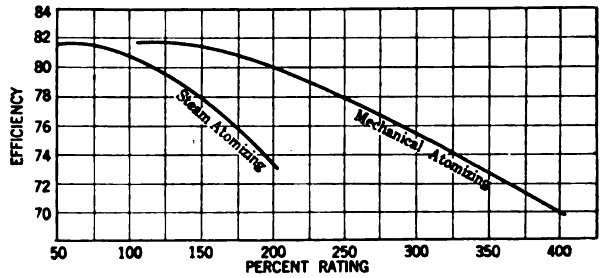

Fig. 1

The use of mechanically atomizing oil burners has been very extensive in marine practise for a number of years but in stationary work experiments heretofore have failed to indicate that there was a marked advantage in their use. It seems to be true that efficiencies with steam atomizing oil burners can be secured as high as or probably higher than with the mechanically atomizing burner, but the writer believes that there have been no tests with steam atomizing burners at ratings equivalent to those reported in the tests herein where efficiencies were secured as high as are shown by those tests.

The Babcock & Wilcox Company is still experimenting with mechanical atomizing oil burners for stationary boiler plants and it is to be understood that later developments may make it possible to secure results even better than those reported herein. However, these results are so satisfactory that it seems

probable that there is a big field for the use of this type oil burner. The Portland Railway Light & Power Company is now installing a Stirling boiler to be equipped with Lodi oil burners.

OIL BURNER TEST—BABCOCK & WILCOX BOILER
BAYONNE, NEW JERSEY

In boiler plants, using oil fuel, where overloads are frequently carried, there has always been a great deal of trouble with refractories. This is particularly the case on the Pacific Coast where the fire brick are not of the very first quality and where the extensive use of oil fuels has forceably brought to our attention the fact that one always has to allow for certain shut-downs for repairs to the furnace brick work.

To help overcome the difficulties with the brick work it has been customary for us to figure on increasing our furnace volumes, particularly where it is necessary to carry overloads. Certainly these increased furnace volumes have helped but have not entirely overcome the difficulty, and the cost of such large furnaces both on account of brick work and the space occupied may be very considerable. With the mechanical oil burner of the type used on the tests above it is evident that since such satisfactory combustion can be secured in a rather limited furnace volume it is reasonable to suppose that we can get along with this type burner in very much smaller furnaces than is possible with steam atomizing burners and still not increase the difficulties with brick work that have been heretofore experienced. The mechanical burner makes efficient use of a much larger percentage of the furnace volume than does the other type, on account of the shape of the flame. The burner makes a much shorter flame than the steam burner because of the finer atomization of the oil and should not require any extra protecting wall in the furnace, such as is frequently used with steam burners.

With mechanical burners it is necessary to have a greater furnace draft than where steam is used, as the air must be delivered at high velocities in order to secure an intimate mixture with the oil. This draft pressure can be either induced or forced as may be necessary. By referring to the tests one will note that it is not necessary, even at heavy overloads, to carry excessive oil pressures, these being well below average steam pressures in modern plants. Temperatures and pressures unquestionably will vary with the quality of the oil but it is probable that even with the heavier oils now being sold no difficulty will be experienced along these lines.

The writer does not wish to recommend unreservedly operating boilers at as heavy overloads as can be secured with this type mechanical burner, because such operation requires the most careful attention; boilers must be clean; and the feed water of the best quality. We usually find very excellent water in the Northwest territory, but in certain plants it may be necessary to purify or distill the make-up and in such instances the mechanical burner eliminates the loss with the steam atomizer.

With the ordinary steam atomizing burner it is frequently necessary to take the burner out and clean it. This seems to be particularly true of the more efficient types of burners using small amounts of steam for atomizing, whereas, with the mechanical oil burner of the type used in the above tests very little difficulty is experienced with burners clogging, although, of course, this trouble cannot be eliminated if the oil is not properly strained, but there is not the probability of carbon

depositing on the burner tip as is frequently the case with the steam atomizers.

The mechanically atomizing burner operates very quietly and on that account in certain installations it would be preferred. Fires are easily lit and put out and burners can be quickly and easily removed. On account of the size and shape of the flame it is also most readily adaptable to installation in existing coal furnaces where oil might be used as an emergency fuel.

In comparing net efficiencies of mechanically atomizing burner installations with the steam atomizing burner one cannot assume that the steam used with the steam atomizing burner is entirely eliminated in case of the mechanically operated burner, for it is necessary to use more steam to raise the oil to a higher temperature and to deliver it at higher pressure in the case of the mechanically atomizing burner. However, the amount of steam used to heat the oil and to deliver it at the pressure required in the one case is probably not as much as the steam used to heat, pump and atomize the oil in the other case, and this is particularly true in the average plant where the greatest care is not exercised in controlling the steam to the burner resulting in a considerable waste at this point.

Summary

Summing up the information contained in this article it seems probable that it will be necessary to curtail somewhat further developments in the use of oil fuel. This leads to the greater consideration of coal which will unquestionably be more extensively used in the future, both in stokers and in powdered form. There is a limited field for the use of sawmill refuse, but where it is possible to secure this fuel at approximately present prices it can unquestionably be used to greater advantage, and a more extensive use of it may develop a better and more efficient means of handling and burning it than we have at present.

A PARABLE ABOUT THE MEAN RADIUS OF THE ELLIPSE

At the recent annual convention of the American Institute of Electrical Engineers a rather heated discussion took place regarding the definition of the power factor of an unbalanced polyphase system. A Joint Committee's report was presented in which N. E. L. A. members participated, and two conflicting definitions were presented. Among those who took part in the discussion was Professor Vladimir Karapetoff, Cornell University, who was opposed to the very concept of power factor in application to an unbalanced polyphase system, and called the procedure "pouring new wine into old bottles." To illustrate his point he told the following parable which created considerable amusement among those present, and helped to swing the consensus of opinion to the rational view advocated. "In a certain country, at a certain stage of its development, the circle used to be the only curve known, and any objects that could not be made square or rectangular were made of circular cross-section. It came to pass, however, that in the course of industrial development the advantages of a flattened circle or ellipse were gradually realized. At first the forms of the ellipse used departed but slightly from the circle, and everyone was speaking about 'the mean radius of the ellipse' without thinking of any exact definition of the term. By and by more oblong forms of the ellipse began to be used, and with them came ambiguities, controversies and even law suits, until it became necessary to appoint a joint committee for the definition of the mean radius of the ellipse.

"The committee began its activities by holding a public hearing to consider the interests of those concerned. First came the representatives of makers of canned meats who stated that the public preferred elliptical boxes of the same height and contents as the former round boxes. So these representatives wanted the mean radius of the ellipse defined as that of a circle of the same area. Next came the makers of labels to go around the sides of the same boxes. They complained that they could not figure out correctly the length of the paper strip for the new elliptical boxes and they wanted the mean radius of the ellipse defined as that of a circle of the same circumference and not of the same area. Finally came the representatives of elliptical pie makers, who wanted two separate definitions for the mean radius of the ellipse. According to them, for selling purposes, the largest radius of an elliptical pie should be defined as its 'equivalent mean arithmetical radius', irrespective of the other dimension. For purposes of taxation the shortest radius should be used and defined as the 'equitable mean geometric radius'.

"The committee was in great difficulty to decide among these proposals, when a shabby looking underpaid college professor appeared and bashfully ventured the opinion that the thing really needed was not a fictitious definition of a mean radius of the ellipse, but a careful study of the actual properties of the ellipse. Then, he continued, the area as well as the circumference of the ellipse could be expressed in terms of its dimensions, and each industry could be provided with the needed data. Besides, such an investigation would open the way to further progress in the arts.

"The rest of the committee and the audience did not like this speech; they rent their garments in wrath, and they took the blasphemous man out of their city to be stoned. Then they delivered him to the judge and the judge delivered him to the attorney general, to be deported with other radicals and criminals who preached violence".

Gaseous Conduction Light From Low-Voltage Circuits

BY D. McFARLAN MOORE

Moore Light Dept., General Electric Co.

THE production of artificial light is one of the most important activities concerning the welfare of humanity. It is a very large subject, since both its practical and theoretical aspects cover vast fields. Yet, there are less than a dozen distinct methods of making light artificially, and some of them are not developed commercially, although theoretically, they possess great possibilities.

This paper is written to consider some of these methods of producing artificial light that have to do with electricity and that come under item 5 of the following list:

1. Torch (and candle)
2. Oil,
3. Gas,
4. Solid Electric Conductors,
5. Gaseous Electric Conductors.

Electricity can be used to agitate into light either solids or liquids or gases. The light of the incandescent lamp is due to electrically-heated solids, and when electricity is conducted by a gas under suitable conditions, light also results. Many varieties of lamps of this nature both in design and construction are indicated in Fig. 1, the scope of which can be enlarged almost indefinitely; for example, by the use of many other gases and vapors.

High-tension lamps require the special auxiliary transforming apparatus to generate the high potential.

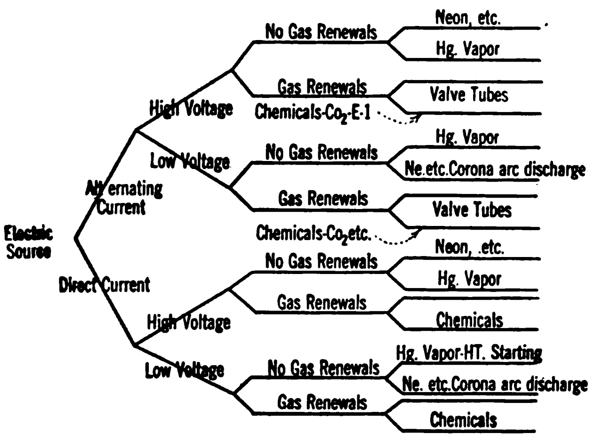

FIG. 1

The two major factors of all of these types are (1) the electrodes, (2) the gaseous conductor.

Both electrodes of alternating-current lamps can be similar, but in direct-current lamps the cathode differs from the anode. Electrode materials differ with the gas used. It is therefore seen that the construction and design of each one of the scores of lamps indicated, is a distinct, and difficult problem, the solution of many of which, has hardly been seriously attempted.

As might be surmised the specific type of lamp I wish to emphasize, is the one that I have been most interested in recently, but in order to give it its proper setting, it is necessary to hastily review the past. The first natural electric light was lightning, or the aurora. It was due to gaseous conduction and so also

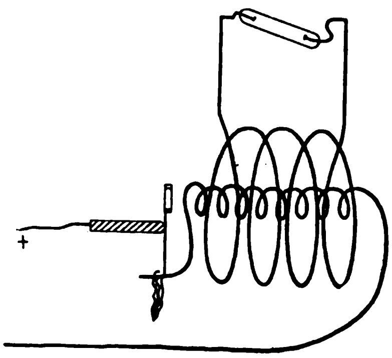

FIG. 2

was the first artificial electric light, which was produced with the revolving glass sphere of Hawksbee in 1750.

A hundred years later, Geissler first operated his small tubes from an induction coil. See Fig. 2. In 1879 Crookes modified them in many ways including obtaining high vacua. About 1891 Nickola Tesla delivered his famous lectures on "High Voltage and High Frequency."

Due to the rapid and very objectionable blackening that was deposited over the inside of incandescent lamp bulbs in 1893, I first began talking and thinking about the possibility of constructing a lamp without a heated filament—a filamentless lamp. In connection with the American Institute of Electrical Engineers, I explained that I meant a bulb form of lamp, the light source of which was to be, not an incandescent solid conductor but to emanate instead, solely from the enclosed gas or vapor electrically agitated by the low-tension circuits in common use.

During the twenty-six years that have intervened, this simple thought has never left me, though the tortuous road has been very dark at times, but it is now brighter than it has been before.

In order that I may not be misunderstood, I must hasten to say, perhaps sorrowfully, that it is still far too dim to even think of its competing in brilliancy with that splendid array of present day commercial illuminants—led by the incomparable tungsten lamp. Dreaming about the "Light of the Future" resulted in the effect shown in Fig. 3.

My first attempts in 1893 to obtain any light from

Presented at a meeting of the New York Section, A. I. E. E., March 26, 1920.

a lamp without a heated filament on 220 volts, resulted in no light whatever. All known gases were unsuccessfully tried. Light from many of the common gases proved very interesting; for example, the bluish white light from CO_2, or the pinkish, hot and almost non-luminous light of hydrogen or the efficient orange yellow light of nitrogen, or the dull whitish light of oxygen; also many mixtures were tried together with chlorine, bromine, etc., and various vapors like those of sulphur or mercury. The prediction was made that progress would only result after the discovery of some of the gases indicated by the table of the periodic law of the elements. It was necessary therefore, in 1894, to resort to the high voltage of an induction coil,

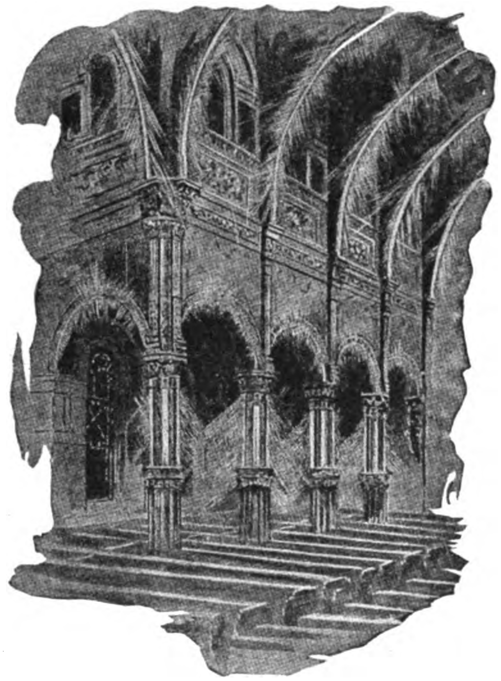

FIG. 3

in order to obtain some light from the first gaseous conductor bulb lamp. In 1895, the vacuum vibrator displaced the induction coil and on direct-current circuits, the bulb lamps were filled with negative glow light. See Fig. 4 which shows vibrator and connections and Figs. 5 and 6 showing negative glow lamps and Fig. 7 depicting the use of negative glow for advertising purposes and means for increasing its intensity. Detailed information of the nature will be found in some of my previous papers.[1]

After neon was discovered as hoped for, and I made nineteen years later, the first low-voltage gaseous conductor lamp, there was a certain satisfaction in proving that my original conception of utilizing the feeble light of the almost despised negative glow was correct. In 1896, seven foot vacuum tubes with external electrodes displaced the bulb lamp. See Fig. 8 for circuits. Fig. 9 shows the meeting hall of the A. I. E. E. thus lighted.

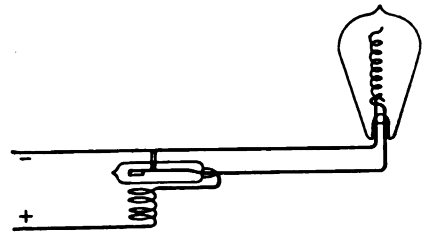

FIG. 4

The vacuum rotator succeeded the vibrator in 1897 and 98. Fig. 10 shows the Rotator Cabinet and Fig. 11 the interior of the historical "Moore Chapel." The first 220-volt direct-current tubes, started with a higher potential, from both vibrator and rotators were made and used. See Fig. 12 for the 5-in. tube which was used in taking the first instantaneous

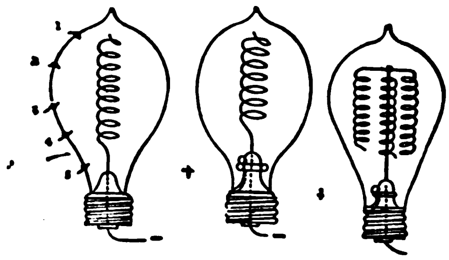

FIG. 5

electric portrait, Chauncy M. Depew being the subject.

The anticipated discovery of neon was announced in 1898, but even samples of it were impossible to obtain in America. Sir Wm. Ramsey, Lord Raleigh, Travers, and their brilliant contemporaries announced in rapid succession the five new monatomic elements, argon, helium, neon, xenon, and krypton, all of which

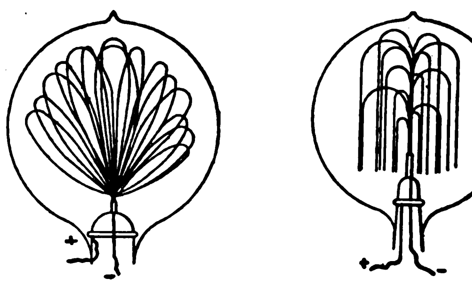

FIG. 6

will probably ultimately take important places in the world of commerce and some of which have already done so.

Vacuum-breaks were displaced in 1899, for a combination of resonance coils and a low-frequency generator, and later high-frequency generators. As shown in Fig. 13 the laboratory was thus lighted.

A New method for the Control of Electric Energy, TRANS. A. I. E. E Sept. 20, 1893.

Recent developments in Vacuum Tube Lighting, TRANS. A. I. E. E. April 22, 1898.

Light from Gaseous Conductors within Glass Tubes, Moore Light, TRANS. A. I. E. E. April 26, 1907.

In 1902, the "long tubes" (about 100 feet) appeared and they were improved in 1903 with internal electrodes. The beauty of the first long tube (Fig. 14)

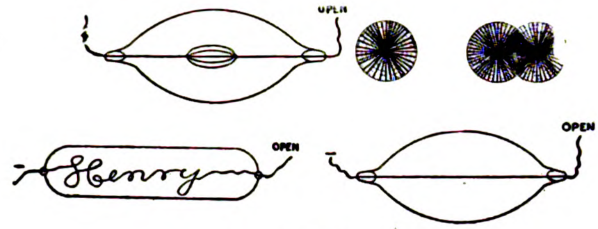

FIG. 7

was admired by thousands. The first rotary high vacuum oil pump was developed for the exhaustion of "long tubes" built in situ. Also a 24-in. CO_2 tube

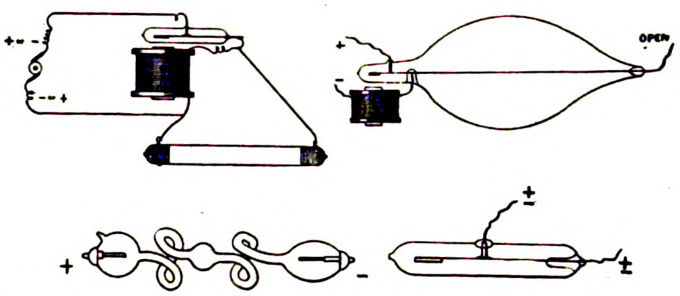

FIG. 8

lamp provided with a carbon filament cathode was started with higher potential on 220-volt direct current and the resultant light was highly efficient.

Other though similar tubes and lamps, had metallic cathodes buried in lime, etc., and it was noted that

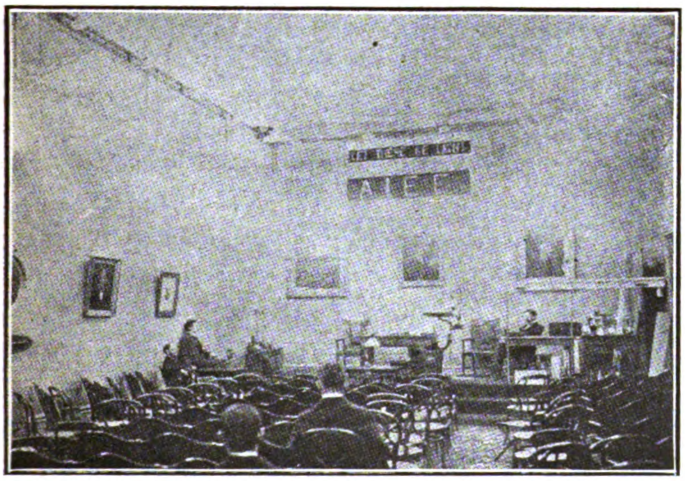

FIG. 9

when operated on alternating current, rectification took place. The combination of chronium and boron nitride with neon and also with some of the gas-feeding methods looks promising. These interesting types of lamps are shown in Fig. 15.

It was a great advance in 1904, and 1905, to discontinue the use of a special generator with each "long tube" installation and obtain brilliant illumination from the distributed street circuits, by the use of nitrogen gas. See Fig. 16. Special electrodes were

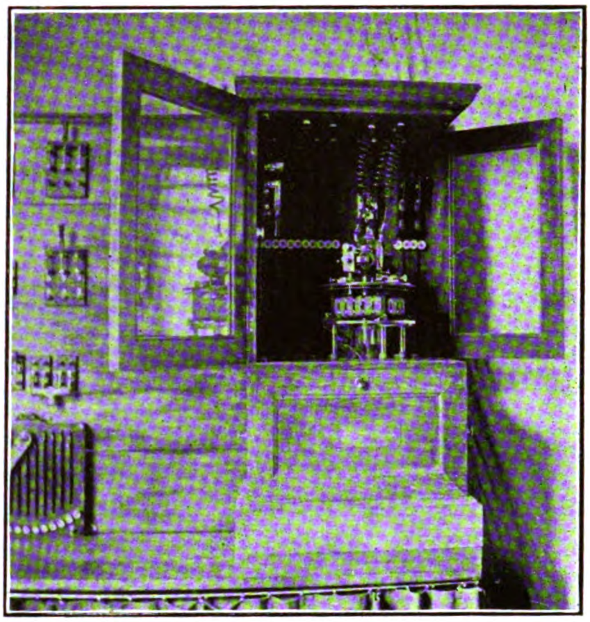

FIG. 10

also constructed with auxiliary circuits, similar to those later used in rectifiers, pliatrons, and X-ray tubes.

The life of these long tubes was extended to 10,000

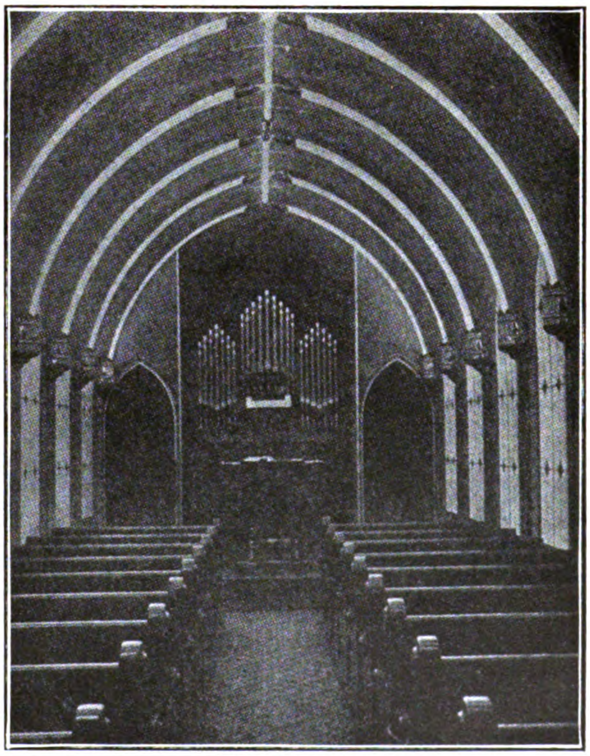

FIG. 11

hours, 1906—1909, by the invention of the electromagnetic feed valve, and over four miles of light-giving tubing was commercially installed. The lobby

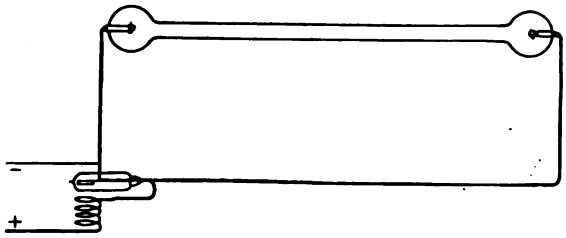

FIG. 12

of Madison Square Garden is shown in Fig. 17. Fig. 18, shows the details of the magnetic feed valve and Fig.

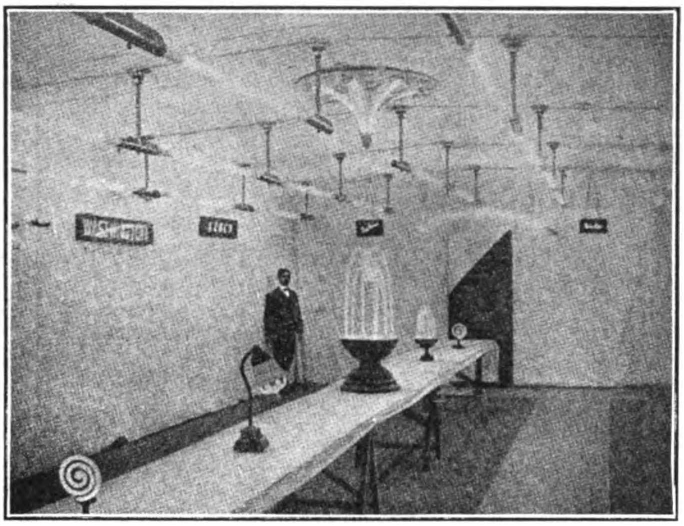

FIG. 13

19, the straight line tubes in the New York Post Office. No light source known today equals in

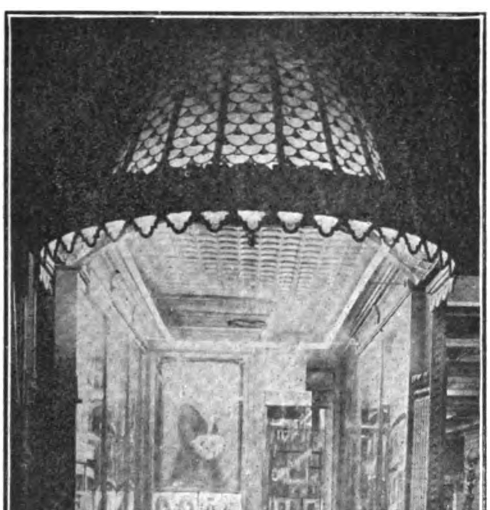

FIG. 14

efficiency a neon tube 1¾ in. in diameter and 200 ft. long. The "long tube" system is theoretically correct in so far as it provides means for generating light at the exact intensity most suitable for the eye; this in contradistinction to the generation of concentrated light at an enormous intensity and temperature that

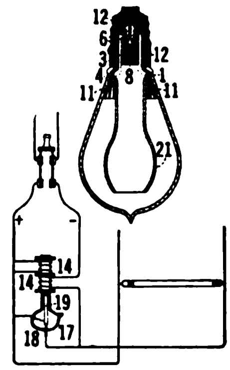

FIG. 15

must, before it can be used by the eye, be either greatly reduced in intensity by means of some kind of semi-transparent or diffusing screen, or widely scattered by a reflector. Fundamentally the first cost of a "long tube" system is less than that of a complete incandescent lamp system and its life is longer with a resulting lower maintenance cost. It is simpler. During 1910-1911, the long tubes in the form of portable artificial daylight windows made their appearance, as shown in Fig. 20.

FIG. 16

Between 1913-1915, several types of small tube lamps, dependent upon the new chemical gas feed principle, were invented and marketed for color matching purposes. The spectrum of this type of color matching lamp will never be surpassed as a standard light by which to judge colors. See Figs. 21, 22, and 23. Simple neon tubes operable from transformers were designed and made in many varieties. Some were equipped with screw lamp bases.

These outfits consume 13 watts and are light enough to be screwed into an ordinary incandescent lamp socket. Lamps of this kind have run without change over 4000 hours.

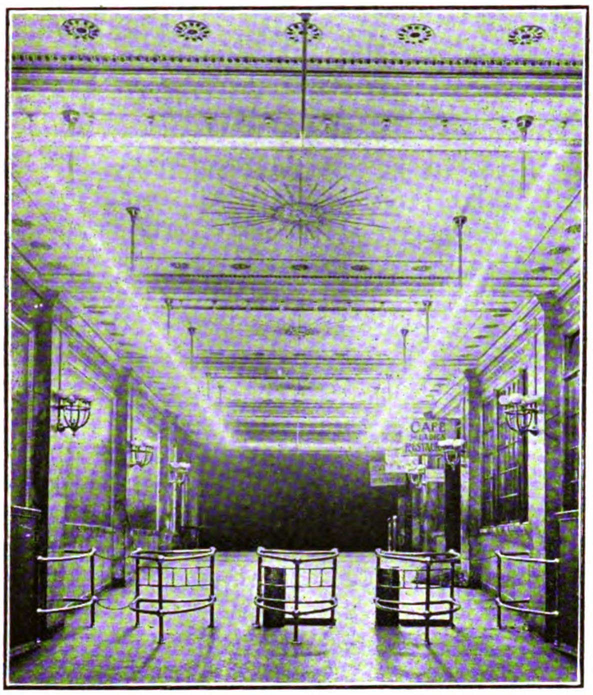

Fig. 17

In the Fall of 1916, there was exhibited the first portable and thoroughly commercial neon tube outfit

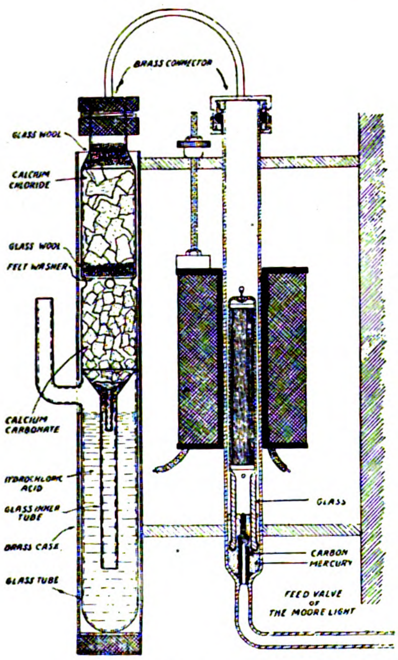

Fig. 18

of high intensity and efficiency operated from a step-up sixty-cycle transformer. It resembles Fig. 21, except that the tube housing is twice as long. The tube was in the form of a hair-pin and had a total gas column length of 101 in. at 7/8-in. diameter. The specific consumption of this type of lamp was 0.74 watts per spherical candle power.

Even this high efficiency can be improved considerably by using purer neon (that is, neon gas that does not contain 25 per cent helium and other impurities) together with a longer gas column of greater diameter. Also the electrode losses can be reduced. But the photometric measurements on this brilliant

Fig. 19

type of tube lamp showed a total of 180 mean spherical candle-power of 2260 lumens with 0.162 ampere passing through the gas column. Simple straight tubes about 1¾ in. diameter and 8 ft. long could be arranged as a continuous line of light and used for

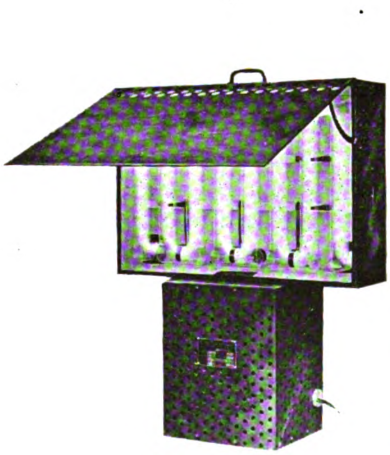

Fig. 20

Fig. 21

the lighting of large interiors or for streets. The initial installations would have great advertising or display worth. The red rays will also be valuable for signaling purposes, etc.

Various alternating-current tube lamps, provided with two similar metal electrodes, were also made to

operate on 220 volts alternating current without a step-up transformer, but they needed a momentary higher voltage to start the gas column discharge which is most simply obtained by short-circuiting a series inductance. The length of the gas column of this type of lamp is too long (about 3 in.) to permit 220 volts to pass any current but it will maintain the discharge, which is positive for an indefinite length

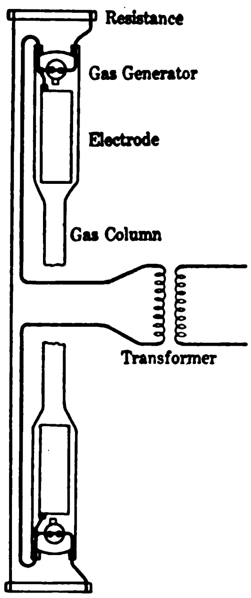

FIG. 23

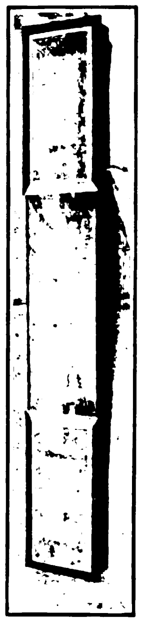

FIG. 22

of time, after once started. The necessity for starting apparatus is an objectionable feature of this particular type of lamp. When the gap or gas column between the electrodes of a tube lamp on 220 volts alternating current is less than about 1¾ in. the light is negative glow.

The direct-current lamp of the type requiring high potential for starting, involves, even when filled with neon gas, a special cathode of mercury of a K-Na amalgam. Still another type of 220-volt direct-current neon tube was started by using an auxiliary current to raise to a high temperature a portion of the cathode. Space will not permit the listing of many other varieties of gaseous lamps.

However it is to the type of lamp that has cold electrodes and is designed to start and operate without using high potential, that your attention is particularly called. As previously stated it is by no means completely developed but it seems to fulfill the original conception of a gaseous conductor lamp without any auxiliaries, for low-potential circuits.

The current of a 220-volt circuit passes through the neon gas and causes it to give light in a manner analogous to the way current passes through a tungsten wire and causes it to give light. No potential raising transformer is required or used. When the particular problem was the production of small units of light, its satisfactory solution by the use of the transformer was commercially impracticable, but it seemed for many years impossible to obtain any light without its use.

Fig. 24, shows a form of this type of lamp, for alternating circuits. Scores of modified designs have been made. It is a novel type of lamp. I hope that many will see in it, with me, the possibilities of a lamp of this kind. In fact diligent inquiry among scientific men has failed to find anyone who did not agree that all theory seemed to indicate the great probability that artificial light of high efficiency will result from the further development of lamps of this kind. The handwriting on the wall seems to unmistakably indicate that to further increase the luminous efficiency of light sources in general, we will need to resort to gaseous radiation, by which means it may be possible to reduce to about one-tenth the energy now required.

Since the ice now seems to be broken on the problem, it is my earnest hope that many of the ablest of inventors will become actively interested, and through the combined knowledge, experience and ingeniousness of all who have studied and worked on gaseous conduction phenomena, the many problems involved will be solved. I believe that a very great deal remains to be learned and discovered.

The lamp shown in Fig. 24 resembles an incandescent lamp in outward form and perhaps is far more simple,

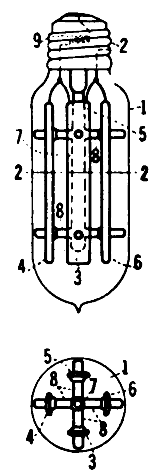

FIG. 24

yet it is not an incandescent lamp. Four electrodes made of aluminum, each 6 in. long, ⅝ in. wide, and $^1/_{16}$ in. thick, are mounted in a 3-in. straight-sided bulb about a common center. A glass bulb, provided with radial arms of glass, supports the electrodes, which have holes in them, and through which the arms extend. The capacity of the solid radiators is objectionable and yet the effect of a solid radiator is approached by radiators, made of very fine meshed netting. An effort was made in designing this lamp, to take advantage of every factor that required minimum voltage so that it would operate on 220 volts or less impressed upon it.

The potential is least (volts per centimeter) for the negative glow. All of the light radiated from this new type of lamp is produced by the negative discharge; —not by the positive column as is the light in all of the long vacuum tubes when in operation from either a-c. or d-c. circuits. All text books and investigators have heretofore considered that the amount of light given by the negative glow in any vacuum tube discharge was so small as to make it entirely negligible as a light source.

An ordinary long tube discharge consists of (a) next to the cathode, the short first dark space (b) the short and not bright negative glow (c) the short second dark space, (d) the long brilliant positive column extending to the anode. But in the lamps herewith described, the positive column has been practically eliminated and substantially the only luminous discharge in the lamp is the negative glow which appears in the form of a velvety glow or corona of yellowish light over the entire surface of the alternating-current electrodes and also a uniform gaseous radiation throughout the entire interior of the bulb.

The lamp shown in Fig. 24, is designed for operation on 220-volt a-c. circuits. At this voltage it uses from the line about 0.11 ampere and 21 watts, but of this amount 3.6 watts at 33 volts is used by an ohmic resistance about 1 in. long placed in the skirt of the lamp base, because due to impurities, principally in the neon gas and the aluminum radiators, a slight blackening may form between them in time, which may cause the lamp to short-circuit.

The finished lamp will probably require no series resistance, but at the present time, the use of such a resistance affords a convenient method of adjusting the total watts consumed, the life or intensity. The specific efficiency of this particular type of lamp is low. When this lamp is consuming 17.4 watts, it gives approximately 1.16 s. c. p., which corresponds to 15 watts per s. c. p. Therefore, the most important problem still to be solved is how to decrease the number of heat waves and increase the number of luminous radiations. When the line voltage was reduced to 135 on this lamp, the light was suddenly extinguished.

The neon used had a helium content of about 25 per cent, but if it had had a nitrogen impurity of a fraction of 1 per cent, the neon lines would have been greatly reduced. The pressure of the gas when sealed off was 3.5 millimeters. The bulb temperature is about 40 deg. cent. but of course is increased when the watts are increased. The color of the light of this lamp is a beautiful yellow.

Some of the important factors given special attention in the designs of this new lamp are:

1. The attempt to use a gaseous conductor of maximum conductivity.
2. Electrodes that are subdivided and of as large a total area as possible.
3. A gas column (discharge gap) as short as possible.
4. The planes of the electrodes of opposite polarity placed parallel to each other.
5. The length of the radiator electrodes greater than the gas column and perpendicular to it.

Since the light is entirely due to negative glow, cathodic disintegration of the electrodes is one of the problems in connection with this type of lamp but it is practically nil when the cathode fall equals its minimum value. It is greater at lower gas pressures and increases as the square of the current, assuming a constant electrode area and gas pressure, but it is not an essential to transmission of current and seems to be largely due to the occluded gases, particularly hydrogen. The bulb blackening is far less with aluminum radiators than tungsten, nickel, copper, etc. Carbon in pure form is difficult to obtain. Iron radiators as well as various radiators combined with fluorescent coatings offer promise.

One of the troubles connected with the use of carbon was the difficulty of removing all of the occluded gases. However, this may be overcome by heating not only carbon electrodes but all other varieties of radiators. Radiators of whatever material should be as pure as possible and be cleansed in the best manner. A combination of light from the glowing gas, and from an incandescent radiator in the same bulb does not seem entirely practical.

This corona type of lamp produces a luminosity that is not due to arcing or even pure discharge phenomena but is due to the glow of light emanating from electrodes or radiators that normally have a temperature below red heat. According to the theory of ionization, the temperature within the negative glow, is higher than within the positive column and the velocity of the negative ion is greater than that of the positive, and this is one reason why the potential required to produce a luminous discharge from a negative pole is less than from a positive, together with the fact that in the negative glow the number of positive and negative ions are about equal.

The exceptional luminous efficiency of neon makes it unique among light sources. Immediately upon the announcement of its discovery in 1898, I proposed its use for lighting purposes. Its great scarcity until recently has made rapid progress impossible. Within the last few days announcement has been made that it can now be bought in almost any quantity and of a high degree of purity. Its luminous spectrum is almost ideally located to affect the eye in a maximum manner. It is a splendid example of selective emission or radiation that eliminates the long and therefore inefficient waves. It does for gaseous conductors just what the Welsbach mantle or the impregnated arc lamp electrode does for heated solids.

The maximum emission is between wave lengths 590 and 650 which is one of the remarkable properties of this gas. It produces over a hundred times as much luminosity for the same watts as does argon for

example. Its dielectric cohesion is 5.6 which is extremely low when compared with air at 419. It has less than one-half the resistance of nitrogen. It is fortunate that the color of the resultant radiation of neon from a positive column is different from that of a negative glow.

Neon gas when used as a positive column of light has a color so reddish that it would be objectionable for

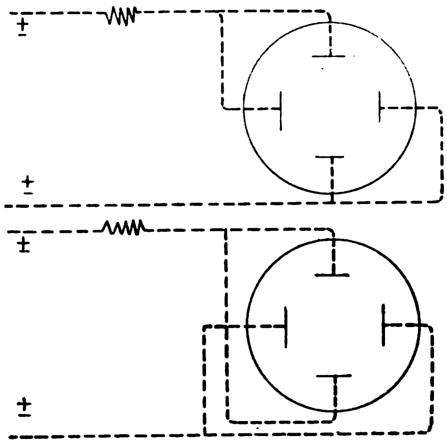

Fig. 25

many purposes but when the same gas is used as a negative glow, the color is yellowish. It has no blue or violet or indigo lines and very few infra red rays. It is four times better as a light producer than the yellow-white light of helium or the violet of xenor, both of which have many infra red rays. The

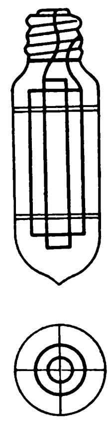

Fig. 26

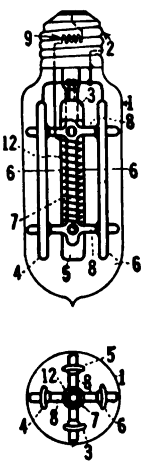

Fig. 27

characteristic crimson of neon has been displaced by a uniform mass of soft yellow light that somewhat resembles the color of a high class oil lamp, or that from the electric incandescent carbon lamp, the intrinsic brilliancy of which is theoretically too great.

The connections of the four radiators are shown in Fig. 25A, but the total flux of light is not very much less when the connections are as per Fig. 25B.

Scores of modifications and varying designs have suggested themselves. For example, such a type of lamp that is suitable for alternating circuits will differ from a properly designed direct-current lamp. But all alternating-circuit lamps will give some light on a direct current of the same voltage. That is, only one of the radiator poles (the negative) will give any light.

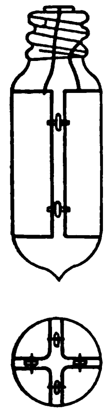

Fig. 28

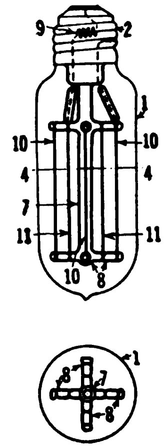

Fig. 29

Therefore, in the case of the lamp shown in Fig. 24, only two of the four radiator plates will be luminous.

The positive poles will remain absolutely dark. This fact is given recognition in the design of the direct current lamp, shown in Fig. 26. The inner cylinder is of sheet aluminum and the outer cylinder is of aluminum netting and made the negative pole.

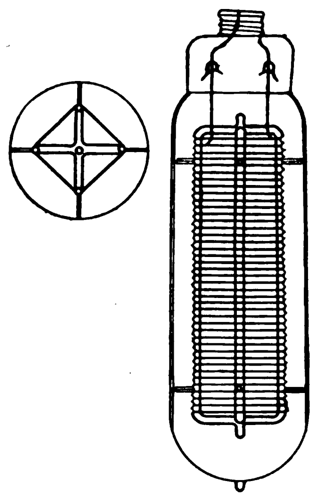

Fig. 30

Fig. 27 which is taken from the United States Patent No. 1,316,967, which was applied for November 30th, 1917, shows the positive electrode in the form of a spiral on the axis of the lamp.

Fig. 28 shows a very simple lamp for alternating circuits that is constructed by inserting into a 3-in. straight-sided glass bulb four right angles made of aluminum netting, of 0.052 wire having a mesh of eight wires per inch. Each right angle is 5 in. long. Eight glass buttons or spacers keep all portions of these four angles at a uniform distance of $^3/_{16}$ in.

from each other, and they are all held in place by the walls of the bulb.

Just as a final mechanical form for the major designs of the tungsten lamp was arrived at, so also will doubtless be the case with lamps or tubes based on the corona principle. These lamps should be so designed mechanically that a maximum amount of the light that is generated has free exit or is reflected in the best manner.

Fig. 29 has a construction that closely resembles that of a standard tungsten incandescent lamp, and Fig. 30 shows wire electrodes wound parallel to each other on a glass drum. Fig. 31 shows such a lamp in the form of a tube.

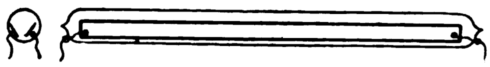

Fig. 31

The dozen most important factors involved in the design of these lamps should be examined theoretically and a definite conclusion reached concerning each one, so as to determine definitely its possibilities.

Some of the important variables are:

The gas pressure, for (a) efficiency, (b) life.

Electrodes; material, form (wire) and area, best suited for a definite voltage, life, wattage, intensity and efficiency.

The exhaust programme.

The length of the gas column, that is distance between radiators of opposite polarity.

Volume and shape of the bulb.

When the gas pressure is too high (about 10 millimeters) no light appears but at 6 milliameters it consists of a velvety or luminescent glow that closely envelopes the radiators but extends further and further from them as the pressure grows less until it fills the entire bulb with a suffused glow, which, however, becomes thinner and less luminous when the pressure is still further reduced.

It seems advantageous to subdivide the radiator of each negative pole. The lamp made as shown in Fig. 32, shows that far more light is generated between such subdivisions than between areas attached to opposite poles.

It is apparent that it is very desirable to produce a brighter lamp. Photometric measurements of lamps constructed as in Fig. 30, showed 2.59 spherical candle power on 220 volts alternating current. The higher the voltage, the easier is this problem. Therefore, perhaps it would be best to first develop a lamp for the commercial 500-volt circuits. When the voltage is raised abnormally on most of these lamps they will arc destructively even though the air gap is large. Often times there seems to be less tendency to this destructive "ball discharge" arcing when the air gap is small, than when it is large, because then the ohmic series resistance can be greater. The lamp as shown in Fig. 24, has a discharge gap of 5/8 in. but in other lamps it varies from 1/32 in. to one inch.

The lamps that give the most light on 110 volts are those whose radiators were made of wire of small diameter and small total area as shown in Fig. 29.

Photometric data of various types of these corona lamps have been obtained by the use of an 80-in. sphere. Color corrections were made by the following procedure:

1. Hold Moore lamp at 220 volts and adjust comparison lamp to Moore lamp color.

2. Set galvanometer on zero and maintain comparison lamp at above color.

3. Adjust Mazda "B" lamp to comparison lamp color and note voltage.

4. Ascertain horizontal candle power of Mazda "B" lamp at above voltage.

5. Horizontal c. p. of Mazda "B" lamp x 0.785—s. c. p. of Mazda "B" lamp.

6. Read Mazda "B" lamp and all d-c. or a-c. Moore lamps against comparison lamp as set.

7. Multiply Moore lamp readings by ratio of Mazda "B" reading to Mazda "B" s. c. p.

The tabulations of Table I show first the performances of four lamps constructed approximately as shown in Fig. 24 on alternating current, and then follow the test data of several lamps of varying constructions.

The tabulations of Table II show most of these lamps when operating on d-c. circuits, under which circumstances of course, but one pole gives any light.

It is only safe to consider these data however as indicating very broad generalizations because no two lamps have been made alike, even as regards their mechanical construction, and they also differ as regards the purity of the gas and its pressure, the exhaust programme, etc. There were also encountered difficulties as regards the photometrical and electrical measurements, for example, when such a lamp is consuming less than two watts, yet the amount of light seems considerable to the eye in a dark room.

Nevertheless, I believe that complete and exact specifications should be determined upon for an ideal lamp of this nature entirely independent of its comparative relations to other and seemingly far superior forms of artificial light.

Some of the conclusions that may be drawn are as follows:

1. Efficiency of these lamps is about the same whether operating on a-c. or d-c. circuits.

2. Efficiency is about the same on a-c. circuits over a wide voltage range.

3. Efficiency is about the same on a-c. circuits over a wide range of intensities.

4. S. c. p. varies approximately with the wattage on either a-c. or d-c.

5. That the lamps with a reasonably pure neon color were not as efficient as those in which gas impurities made the color whiter.

6. The general lamp performance is not very sensitive to wide variations in the length of the gas column or gap.

7. The same lamp equipped with the same resistance and operating at the same voltage takes a considerably higher line wattage on a-c. than on d-c., which doubtless is principally due to the light radiating area being double.

8. The c. p. is greater with radiators of large area.

9. The power factor of these lamps is about 85 per cent.

These lamps demonstrate that useful gaseous conductor light, that, to say the least, has advertising value, can now be produced in a simple manner from ordinary commercial circuits. Special uses will be found for such lamps for example as polarity or potential indicators. Since the internal parts are all below red heat gas explosions will not be caused by bulb breakage. Gaseous light, due to electrical agitation has, to a limited extent, been emancipated from all necessity for a heretofore ever present high potential either for starting or normal operation. The basic conception of using a gas to supplant the heated filament in an ordinary lamp seemed wholly impossible, yet, this new type of lamp makes it at least a partial reality. It constitutes an advance in that it adds to our knowledge of a very little developed subject. A new epoch in the history of gaseous conduction lighting has been reached. It is my hope that the great cause of new and better lighting methods in which my deep interest has been centered for years, may be spurred to rapid advancement in a new direction that gives promise of reward to an unlimited number of worthy investigators and inventors.

Installation and operation of electric machinery for handling all materials in manufactories, depots, terminals and other commercial places offers the greatest potential field for development in the industry today, stated Zenas W. Carter, manager of The Material Handling Machinery Manufacturers' Association, of New York City, in his address before the fourth general session of the N. E. L. A. Convention.

Only five per cent of the potential demand for handling machinery has been met, and, since 85 to 90 per cent of all material handling machinery is electrically operated, the opportunity may be realized.

High wages, labor shortage and need for speeding up of production are given as the three cardinal reasons why every effort should be made to develop this field as speedily as possible.—*N. E. L. A. Bulletin.*

Technical Committee Reports

ANNUAL REPORT OF THE ELECTROCHEMISTRY AND ELECTRO METALLURGY COMMITTEE

To the Board of Directors.

THE chairman of the Electrochemistry and Electrometallurgy Committee for the year 1917–1918 suggested to the Board of Directors of the American Electrochemical Society that it should approach the A. I. E. E. with the idea of forming a joint committee to consider matters that were of common interest to the two societies. Such a committee could consider papers which might be of importance to both societies, could bring to each society's attention matters of common interest and make arrangements for occasional joint meetings. The result was that the Board of the American Electrochemical Society appointed Messrs. Fink, Parmelee and Schluederberg "to cooperate with" this Committee.

Nothing was done in this matter in the year 1918-1919; but this year it was taken up again with the result that a joint meeting of the A. I. E. E. and the A. E. S. was held in Boston April 9th, 1920. The meeting was successful, the combined registration amounting to about 425, with the result that the seating space of the rooms used for meeting was somewhat overtaxed.

It is believed that the occasional holding of joint meetings with the A. E. S. similar to that held this year is desirable and it is suggested that the plan be followed up next year when an even more successful joint meeting might be held. The weak point of the April meeting was the failure to print in advance some of the papers presented at the meeting by members of the A. I. E. E. The blame for this rests with the chairman of your committee who had not provided for his unforseen detention in Europe during the first part of the year, with the result that sufficient time was not given to authors to prepare their papers before the meeting. The printing of the papers in advance of the meeting is important so as to stimulate discussion and the exchange of views between the members of the two societies which have so much ground of common interest.

FRANCIS A. J. FITZGERALD, *Chairman.*

ANNUAL REPORT OF THE COMMITTEE ON ELECTRICAL MACHINERY

To the Board of Directors.

THE Committee on Electrical Machinery placed before itself the aim to cover as nearly as possible the range of work in which there had been changes of importance which had not yet become a matter of record in the TRANSACTIONS of the Institute.

The Committee joined with other committees in the presentation of papers at the Midwinter Convention on the general subject of super power stations for the eastern coast states. This subject will receive renewed attention from time to time.

The polyphase alternating current commutator motor for variable speed operation received comprehensive treatment in two papers, one by B. G. Lamme, presented before the Schenectady Section, and the other by John I. Hull, to be presented at the Annual Convention.

The subject of temperature measurements in large alternating current generators and allied questions received a complete and exhaustive treatment in four papers to be presented at the Annual Convention. Rationalization of temperature measurements and uniformity of policy have been established as a result of these papers and of the investigations which led up to them.

A mathematical paper by R. E. Gilman discusses the losses due to eddy currents in stranded conductors embedded in slots, thus carrying on further the fundamental work begun by A. B. Field.

A symposium of papers on the design and the operating characteristics of welding machinery has been arranged for the Annual Convention so as to make a record in the TRANSACTIONS of the progress made in this important direction.

In presenting this brief report, the Chairman desires to point out that he has considered it the essential function of his Committee to trace, through the papers solicited and the meetings arranged, the progress of the art which it was desired to record. Thus it is unnecessary to deal again here with the subject matters comprehensively presented in the papers.

In conclusion, the Chairman wishes to thank the members of his Committee for their support and co-operation.

B. A. BEHREND, *Chairman*

ANNUAL REPORT OF THE PROTECTIVE DEVICES COMMITTEE

To the Board of Directors.

EARLY in the year the Protective Devices Committee appointed a number of sub-committees to investigate, study and report on various subjects and these are discussed in some detail in the following summary.

SUB-COMMITTEE ON TERM, "INSTANTANEOUS RELAY"

E. E. F. CREIGHTON, *chairman*

This Sub-Committee resulted from the criticism of the term "instantaneous" as applied to a relay, it being contended that the term did not properly describe the device. A number of other terms were suggested of

which the term "quick acting" appeared to have the preference. On account of the wide diversity of opinions among the members of the committee on the subject, no definite recommendation has been made, and it was agreed that the Chairman of the Sub-Committee would summarize the various opinions on the subject and submit them for publication in the JOURNAL.

SUB-COMMITTEE ON SCHEMES OF RELAY PROTECTION

P. H. CHASE, *chairman*

Following the recommendation in the Report of the Committee last year, a number of letters were written to the executives on a selected list of operating companies, and about thirty-five replies have been received from companies who were willing to cooperate in the work assigned to this sub-committee, and one of their engineers delegated as the correspondent on the subject. Questionnaires regarding schemes of relay protection have been forwarded to these correspondents. The United States and Canada has been divided into six geographical sections and each section has been assigned to a member of the sub-committee who is with an operating company in that district. These members are charged with examination and classification of replies received and with distribution of the information to the other members of the sub-committee. It is felt that the work of the sub-committee to date has been very largely of a preliminary nature and that its value will be more apparent later in the year.

SUB-COMMITTEE ON OIL CIRCUIT BREAKERS AND SWITCHES

H. R. WOODROW, *chairman*

This Sub-Committee is cooperating with similar committees of the National Electric Light Association and the Power Club, and is securing information on the subject from a limited number of the larger operating companies. There has not been sufficient time since the request for information was issued, to secure answers from the various companies and to summarize the results. The subject of high-tension fuse protection has also been referred to this Sub-Committee.

SUB-COMMITTEE ON SYSTEM DISTURBANCES

D. W. ROPER, *chairman*

It was the opinion of a number of members of the Committee that the serious system disturbances experienced by the operating companies were due in a large measure to the defective action, or perhaps the absence, of suitable protective devices, and that a study of such disturbances might indicate the lines along which the future work and study of the Protective Devices Committee should properly be directed. The members of the Sub-Committee are interchanging information on this subject and in recent months have been somewhat embarrassed by the amount of data available. An unusually large percentage of the larger operating companies have experienced severe system disturbances and in some cases the behavior of the protective devices was an important factor in the disturbances. The Sub-Committee is now endeavoring to formulate some standard method of reporting on such matters, so that the reports can be properly condensed and summarized and be made available for the purposes of the Protective Devices Committee.

SUB-COMMITTEE ON REACTORS

F. E. RICKETTS, *chairman*

In the last few years there has been a marked improvement in the design of reactors such as, methods of winding to reduce eddy currents, improvements in structure to increase the insulation strength, and to work the copper to the best advantage. In some cases this improvement in design has been taken advantage of to reduce the size of the reactor so that the coils of today are small when compared with those of equal rating built a few years ago. This, however, is not a feature that should be carried to extremes as the current limiting reactor is, fundamentally a protective device and this function should be fully recognized in its development. Every effort should be toward the perfection of the design to avoid failure of the device itself and at the same time avoid the reduction of any of the protective features.

The application of reactors has been reviewed at different times in papers presented before the Institute and various schemes of connection have been proposed; but there is still some difference of opinion as to the proper place to insert reactors to obtain the best results, and there are many factors entering into this question. Each application requires a separate study but in general the best protection for the service is obtained by installing the reactors in individual feeders, and this is the practise followed by most companies provided the necessary space is available. However, some engineers prefer to sectionalize the system by inserting reactors in the bus, but when this is done, consideration should be given to the possbility of increasing the chance of the different sections getting out of synchronism which becomes very much of an operating menace where the amount of reactance in the circuits of the generators is much greater than that necessary to give the greatest synchronizing power.

SUB-COMMITTEE ON RESISTORS FOR USE WITH POTENTIAL TRANSFORMER FUSES

R. N. CONWELL, *chairman*

One of the larger companies in New York has made some elaborate and complete short circuit tests on potential transformer fuses installed with and without protective resistors in series. Following these tests a number of companies in and around New York have adopted the standard practise of installing protective resistors in series with the potential transformer fuses which are connected to their high-tension buses for the purpose of limiting the current, and in this manner

preventing damage to apparatus or interruption to service which had previously occurred. A summary of the results of the investigations, with the practise of the several companies is being prepared for submission to the Publication Committee for use in the JOURNAL. A canvass by the Chairman brought forth the information that certain other companies are using a different type of fuse which has given excellent results in service, and which does not require the use of a protective resistor in series.

PRIMARY CUTOUTS FOR LINE TRANSFORMERS

This subject was discussed at some length in the meetings of the Committee. It was the opinion of a number of the members of the committee that are connected with operating companies that the development of primary cutouts for line transformers had not kept pace with the development of the transformers themselves. One company reported they had considerably more trouble originating in the primary cutouts than in the transformers which these cutouts were intended to protect. Several of the larger companies install the larger sizes of overhead line transformers and all sizes of subway types of transformers in manholes without any primary cutout as their experience indicates that they have fewer interruptions in this manner than they would if they attempted to use cutouts with these transformers. It is the opinion of the members of the Committee that if the larger manufacturing companies would devote as much engineering skill to improvements in primary cutouts as they do to improving the design of line transformers, this difficulty which is one of long standing, would very quickly be eliminated.

During the discussion of the subject of primary cutouts it was brought out that one of the largest companies had, some years ago, abandoned the use of all types of cutouts or lightning arresters which were enclosed in an iron case. This was found necessary on account of the troubles with these devices during rain storms and wet snow storms, and that the difficulty had increased with the size of the generating or transforming units which supplied the current to the lines on which these devices were installed. During the past year another large operating company has taken exactly the same action and for the same reason. The Committee therefore, recommends that operating companies take note of this situation as with the increase in the size of their generating and transforming units they will ultimately be called upon to take similar action and they should, therefore, investigate types of such devices without the metal enclosing case with a view to its adoption for their future work.

During the year the Committee has undertaken to make investigations which will not be completed during the fiscal year. The Committee members who are taking an active part in this work all feel that the work is not only of particular interest to the members of the sub-committees, but should ultimately result in something of value to the Institute. It is recommended that the investigations of these subjects be continued next year, and that the members of the sub-committees who have been actively engaged in these several investigations be continued on the Protective Devices Committee during the ensuing year.

D. W. ROPER, *Chairman.*

ANNUAL REPORT OF COMMITTEE ON INSTRUMENTS AND MEASUREMENTS

To the Board of Directors.

THE Instruments and Measurements Committee submits the following report covering its own activities during the past year and the developments and progress in that part of the electrical field covered by its title.

A considerable number of papers was arranged for during the year and at the Mid-Winter Convention in February, one morning session, one afternoon session and part of a second afternoon session were assigned to this Committee. A most interesting and valuable group of papers was presented. The sessions were very well attended and the discussion was limited only by the available time.

The papers presented at the sessions referred to above are as listed below:

1. "Measurements of Projectile Velocities" by Dr. P. E. Klopsteg and Major A. L. Loomis.
2. "A New Form of Vibration Galvanometer" by Mr. P. G. Agnew.
3. "Precision Galvanometer for Measuring Thermo E. M. Fs." by Messrs. T. R. Harrison and P. D. Foote.
4. "Notes on Synchronous Commutators" by Professor J. B. Whitehead and Mr. T. Isshiki.
5. "Oscillographs and Their Tests" by Professor A. E. Kennelly and Mr. A. A. Prior.
6. "The Accuracy of Commercial Electrical Measurements" by Mr. H. B. Brooks.

Without entering into a complete review of all the papers or the discussion, brief mention should be made of the paper on the Check and Calibration of Oscillographs and the paper on the Accuracy of Commercial Electrical Measurements. The oscillograph is rather generally used as a means of practically ultimate analysis of electrical functions and phenomena, and the paper provides the means of checking the functions and characteristics of the oscillograph itself. The contribution to the papers of the Institute entitled "The Accuracy of Commercial Electrical Measurements" is a most thorough and comprehensive analysis, review and statement of the characteristics and limitations of the many commonly used electrical instruments. This paper will, without doubt, serve as a ready reference for many years and should be of value to many engineers in other than actual testing

work. It covers in a thorough and intelligent manner the errors that may be expected in the use of various instruments under various conditions.

The definition of power factor in polyphase circuits is a matter that has been active and of interest from many angles throughout the past year. While it has been the direct work of a Special Joint Committee of the N. E. L. A. and the A. I. E. E., its work falls within the general purview of this committee and a brief mention in this report seems entirely proper The Special Joint Committee canvassed the manufacturing, operating, scholastic and purely engineering branches of the electrical industry and prepared a report of its findings. It was intended to have this report presented at the Mid-Winter Convention last February. It was impossible, however, to analyze and intelligently condense in the form of a report, the volume of material received. It was decided, therefore, to have the report ready for presentation at the Summer Convention of the A. I. E. E. and to have a session assigned to the general subject. Arrangements will be made for discussion by various interested individuals to present the point of view of various interests affected by the settlement of the question. It was hoped that this method of procedure would provide an adequate form for the use of the many interested individuals and permit the ultimate acceptance of a satisfactory solution of the question.

Your committee has surveyed the field of manufacture of instruments and measuring devices and finds in general a few reports of new developments, some reports on standardization and adaptation to commercial usage of the designs dictated by the war and practically unanimous reports from all of the manufacturers of extreme difficulty in contending with the shortage of material and labor turnover in the production of the standard and accepted lines of apparatus.

The various companies manufacturing watthour meters and demand devices, practically all report the completion of experimental models, finished designs or actual production of devices for measuring kv-a-hr. and demand devices for measuring the demands of kv-a. and kw. and power factor. These various devices may make the measurements separately or simultaneously on a single record. Further there is a steady continuation in the development and standardization of maximum-demand devices to complete the series of devices suitable for easy adaptation to d-c. watthour meters, a-c. watthour meters and various frequencies.

Aside from the adaptation to various types of meters there is the continuation of the development providing devices actuated on the time basis, either on spring driven clocks, spring driven clocks electrically wound or motor driven clocks.

The Warren motor referred to in last year's report of this committee continues to be developed in a most satisfactory manner. It is being used for the control of frequency on generating systems through the master clock. It is also being installed in many forms of graphic and recording instruments used for various purposes throughout the stations of generating and distributing systems.

In the field of indicating instruments, both for direct- and alternating-current use, it is found that the designs which were developed particularly for war purposes, have been modified sufficiently to meet the regular demand and there are now available lines of both switchboard and portable types of instruments that were not available two or three years ago. These instruments are in general of a very satisfactory type and serve a very useful purpose in providing other sources of supply of instruments which did not exist some years ago.

The greatly increased activity in the measurement of high frequencies used in wireless work caused the development of vacuum thermal converters. These devices serve very satisfactorily for other purposes than for wireless work inasmuch as they permit the precise measurement of extremely small values of alternating current, a field of measurement which has not until recent times been covered by other than laboratory instruments.

In canvassing the field of telephone and telegraph engineering for instruments and measurements, the committee finds in answer to inquiry practically nothing to report, but mainly the continuation of developments which were started during the war period and previously reported.

Reports from those companies specializing in the manufacture of laboratory and precision instruments indicate a very valuable development of this type of instrument for certain special as well as general purposes. The line of development has been to produce on a commercial scale automatic precision electrical instruments, either of the indicating or the graphic type. Wheatstone bridges and potentiometers are normally considered as indicating instruments or devices manually operated by means of dial switches or plug contacts. One of the companies manufacturing this type of apparatus reports the development of an automatic potentiometer and an automatic Wheatstone bridge, both used for recording or controlling processes or a combination of the two. These automatic equipments are supplied for the control of chemical and electrochemical processes and some installations of these are in actual use. For chemical and electrochemical work the automatic Wheatstone bridge can be operated on a commercial 60-cycle a-c. circuit and a special a-c. galvanometer has been especially developed for this equipment.

Two of the important applications of the a-c. Wheatstone bridge equipment, are the recording of surface condenser leakage in power plant operation and the controlling of the finish point during the evaporation process in plants making condensed milk. The

potentiometer equipment is also used for accurately recording and even controlling the acidity and alkalinity of solutions through the measure of the potential between two electrodes immersed in the liquid.

The recording or indicating potentiometer when used in connection with thermocouples produce a very satisfactory and accurate record of temperature. The measurement of temperatures is, of course, directly related to design and operating requirements of electrical apparatus and these devices serve very satisfactorily indeed to analyze the daily or weekly cycles of thermal performance of cables, transformers, turbine generators or in fact any of the various commonly used types of apparatus in generating and distribution systems.

S. G. RHODES, *Chairman.*

ANNUAL REPORT OF THE TELEGRAPHY AND TELEPHONY COMMITTEE

To the Board of Directors:

FOLLOWING out the plan adopted last year as to the form of annual report to be submitted by the committee the following report includes references to technical progress only. The report is made up of contributions forwarded by each member of the committee.

STANDARDIZATION

During the past year considerable progress has been made in standardizing telegraph and telephone practises of the railroads of this country and Canada. Committees composed of representatives of the railroads, the commercial telegraph and telephone companies, and various manufacturers of apparatus, have prepared specifications for materials, apparatus and methods which, while conforming to the generally accepted standards in each case, include special features adapting them to railroad requirements. It is expected that these specifications will be formally adopted by the American Railroad Association in the near future, and that the desired approach to uniformity of practise will soon follow.

TOLL LINE CONSTRUCTION

Toll circuits may be composed of either open wire on pole lines, aerial cable, or underground cable. Any one of these will give high grade transmission when improved equipment and methods of operation are used. Therefore, the tendency in toll line construction is to build plant which will be most economical and at the same time reduce the cases of interference to service from storm breaks and various other troubles to a minimum.

Underground cables properly installed and maintained are open to the least interference to service. However, it is not economical to place underground construction unless more than two full-size cables are required. Generally, underground cables cannot be justified except between the larger centers and their surburban sections.

Aerial cables are liable to less interference than open wires, but economy restricts their use largely to cases where the existing number of circuits and the rate of increase require extensive rebuilding, or additional pole lines to continue on an open wire line basis. Where the number of circuits will not justify aerial cable, open wire circuits must be constructed and maintained.

UNDERGROUND CABLE CONSTRUCTION

No radical changes have recently been made in engineering or construction methods involved in connection with laying of underground cables. The maximum size of cable used contains 1200 pairs of No. 24 B. & S. gage wires. Experimental work is being carried on for the purpose of increasing the number of wires without increasing the diameter of the cable sheath.

Troubles in underground cables have been due in part to disorderly arrangement of cables in manholes and the manner in which the splices were made. Great stress is now being laid upon the importance of having the manholes in good condition, supporting the cables in an orderly manner, and making splices with extreme care. The cost of labor required for installing underground cables is relatively small compared with the total cost of the cable in place, and therefore it is felt that all reasonable efforts should be made to install and splice the cables in such manner as to reduce the cable troubles to a minimum.

INDUCTIVE INTERFERENCE

The Railroad Commission of the State of California has recently published a comprehensive work entitled, "Inductive Interference," in which is given a large amount of technical information gotten together by the Joint Committee on Inductive Interference, which investigated this subject in California over a period of about five years. This work makes available to interested parties a great deal of information of fundamental importance.

The activity in both the power and the communication fields since the war, has demanded renewed close attention to the study of inductive interference.

The growing use of electric arc furnaces which usually produce great distortion of wave form has given rise to serious new problems in noise interference prevention.

The methods of overcoming interference with communication circuits from abnormal conditions on adjacent power circuits have not been so well developed as the methods of overcoming disturbances from the normal operation of power circuits. Constant increase in the amounts of energy carried by power circuits has also made these problems more difficult. Especial attention must be given, therefore, to this phase of interference, particularly along the lines of limiting

the number of abnormal conditions, reducing the length of time in which the circuits are abnormal and in limiting the magnitude of unbalanced power currents during such abnormal periods.

Information on the subject of interference from electric railways has been increased by two or three important investigations, but is still far from complete.

Printing Telegraph Tendencies

While the invention of systems of printing telegraphs has been active substantially since the introduction of Morse's telegraph in the year 1844, the use of printing telegraphs on a commercial scale in America—aside from stock and news ticker systems—has been extensive only since about the year 1900. During the past twenty years improved printing telegraph systems have been extensively applied in moving traffic over trunk circuits where the volume of business is heavy and continuous. On the lines of the Western Union Telegraph Company practically 80 per cent of the trunk line traffic is so despatched. The Postal Telegraph-Cable Company, on the other hand, makes no use of printing telegraph systems at the present time. On railroad telegraph lines printing telegraphs are used also to a large extent.

The next stage of development—now very likely close at hand—is the application of printing telegraphs to wider uses and to circuits having a much lighter than trunk line traffic load. Extending to light-load circuits the use of printer systems makes simplicity of operation, low first cost, and low maintenance cost of first importance.

With the object of meeting the requirements for simplification work is now under way with tape printing devices. Also, it is probable that two or three other systems of simplified telegraph printing will be given trials in service before long.

Radio Signaling

The year 1919 has seen the application of discoveries and inventions which were necessarily veiled in secrecy during the years of war. Under stimulus of war necessity remarkable progress was made in the application and extension of the known principles of the art, standardization of radio apparatus and of its quantity production and use. These advances were made possible by the cooperation of industrial companies, their engineers, and engineers and scientists with academic connections. The efforts of these individuals or groups were ably coordinated and stimulated by the military and naval branches of the Government.

Progress during the past year has been more in the nature of a consolidation of the scientific advances of the war time than in the nature of an entry into new fields. The entire art of radio communication now stands on a firmer basis, with a greatly enlarged personnel of trained engineers and research investigators.

Radio telephone communication was maintained between the seat of Government and the steamship George Washington, on which President Wilson made his European voyages. In these demonstrations the radio station at New Brunswick, N. J., was used.

The guidance by radio of airplanes engaged in peace-time activities is well illustrated in the directing towards landing places of the planes of the Post Office Department. Communication with planes on long voyages was accomplished in the memorable voyage of the N C-4.

High-speed radio telegraphy has been greatly accelerated by the use of the Hoxie recorder and the Alexanderson magnetic amplifier. Direction-finding by radio compasses and its corollary of directive-receiving has been placed upon a firm scientific basis.

The possibility of selecting signals with reference to their direction has been successfully applied by Weagant, Wood, Taylor, Alexanderson, and others, to the selection of desired signals and the discrimination against atmospheric disturbances and signals of foreign stations. These principles have also permitted engineering advances in duplex, or two-way operation of pairs of stations, and in increased possibilities of multiplex transmission and reception. Knowledge and experience along the lines of duplex and multiplex operation has given added interest to the questions of regulation of wave length, range, and of the effect upon radio development of legislative action.

In the manufacturing field there has been progress not only in standardization of apparatus and in better performance, but also in the production of equipment for high-power continuous-wave stations; compact and simple apparatus for medium-power stations and short-range sets suitable for amateur use.

The withdrawal of military restrictions has resulted in a stimulus to amateur operation. By the encouragement of amateurs and of the research departments of the universities and engineering schools, the art should attract additional workers and provide for its future the necessary increase in an enthusiastic and well-trained personnel.

Automatic Telephony

During the past year there was begun a movement which may become general looking to the converting of manual telephone exchanges to automatic operation. The same movement is said to be under way in foreign countries. From the mechanical standpoint there were no outstanding improvements in automatic telephony brought into public use. Progress took the form of a general refinement of details necessary to meet operating conditions.

DONALD MCNICOL, *Chairman.*

ANNUAL REPORT OF THE COMMITTEE ON TRANSMISSION AND DISTRIBUTION

To the Board of Directors.

THE Committee on Transmission and Distribution submits the following report for the year 1919-1920:

General

Early in the year the Board's Committee on Technical Activities suggested that it might be advantageous to change somewhat the character of the Annual Reports of the Technical Committee so that each of these reports would become an authoritative source from which could be obtained a complete resumé of developments in its particular field.

This matter was thoroughly discussed at a meeting of the Technical Committee Chairmen, who were of the opinion that it would be inadvisable to take such a step

The chief objections to the plan may be summed up as follows:

1. The preparation of a really complete and authoritative annual resume by each Technical Committee would require a great deal more time than could possibly be devoted to it by the Committee members.

2. Several publications prepare annual digests of developments and an attempt by the Institute to prepare similar statements would be more or less in the nature of duplication.

3. The preparation of a summary by the Committee instead of the present method of reviewing papers presented, would eliminate the personal element. This might tend to take away the incentive which now exists for the preparation of papers, as under present conditions, the preparation of papers is solicited, and when abstracted for the Annual report, full credit is given to the author.

It therefore seems that the advance in the art is best recorded by the present methods, and that those who desire a summary of developments, obtain this summary in a more accurate form than would be possible if the Committee's Annual Report were to deal in generalities.

During the year your committee in conjunction with the National Electric Light Association Underground Systems Committee, formed a joint Sub-committee on Cable Specifications.

This Sub-committee, after a number of conferences in which practically all the cable manufacturing companies were represented, completed its standard specification for paper insulated lead covered cable. This specification, which is accompanied by an appendix giving very complete notes explaining the various clauses, is printed in full as part of the report of the Committee on Underground Systems of the National Electric Light Association. The specification is also printed in pamphlet form for general distribution among cable engineers.

As a result of this standardization, cable manufactured under these specifications will be of the first quality and in accordance with the latest and best practise.

In addition to the work on preparation of cable specifications, this Joint Sub-committee is also preparing data and carrying on investigations of the dielectric losses in cables, relation of heating of cables to their load-carrying capacity, and such other information as is essential to the proper operation of underground cable systems.

In this connection, the Sub-committee has plans under way for the construction of an experimental conduit line about 200 feet in length. With the facilities offered by this experimental line the following phases of the problem will be investigated:

1. Relative temperature drops taken up by the cable insulation, air surrounding the cable, duct walls and surrounding soil.

2. Determination of watts lost as related to the temperature curve under various conditions.

3. Best arrangement of ducts to reduce heating to a minimum.

4. Determination of a reliable method of rating cables.

Papers on Transmission and Distribution

There has been considerable discussion during the past year of the desirability of erecting high-voltage tie lines to connect existing or proposed, large power developments.

A paper presented at the Pacific Coast Convention in Los Angeles, September, 18th, 1919, by Messrs. R. W. Sorensen, H. H. Cox and G. E. Armstrong, deals with the high-tension tie line in so far as the state of California is concerned.

The authors summarize the power resources of the state, estimate the probable 1926 demand, and discuss the advantages of an all state tie line. The paper points out that the fundamental problems in 220,000 volt transmission are well understood, and that as the need of such a line is imperative, arrangements should be made without delay for the working out of details, and the construction of the line.

The super-power generation and transmission problem for industries and railroads on the North Atlantic Seaboard has been very thoroughly covered in a paper in the JOURNAL for March, 1920, by Mr. W. S. Murray.

The author's plan, which has the endorsement of the important engineering societies, provides a means whereby the present estimated machine capacity of 17,000,000 horse power, divided 10,000,000 for industrial and 7,000,000 for railroad purposes, in the region between Boston and Washington, can be lifted from a present load factor of 15 per cent to a load factor of 50 per cent or more.

By utilizing the more economical generating apparatus at such a high load factor, it is expected that present fuel consumption can be cut in half and that

the railroads can be relieved of carrying a considerable amount of the coal which is annually transported to the seaboard.

In conjunction with Mr. Murray's paper there also appeared in the March, 1920 JOURNAL, a symposium giving the views of a number of eminent engineers on the subject of super-power generation and transmission.

In the April, 1920 JOURNAL, Mr. H. H. Plumb has contributed an extremely interesting paper on a rational method of determining the economic voltage for a long transmission line. The paper presents a rapid solution for the size of copper conductor based on Kelvin's law, and with this as a foundation, develops the solution of the economic voltage for copper, copper-clad steel, aluminum and other conductor materials.

Mr. W. A. Del Mar in the January, 1920 issue of the JOURNAL, has worked out a method by which different insulating materials may be compared even when the tests are made at different voltages, and on cables of different sizes. This method consists in expressing the specific quality of the insulation, in terms of a quantity which may be termed the coefficient of dielectric loss, and which is the product of the power factor and the specific inductive capacity.

TENDENCIES IN HIGH-VOLTAGE TRANSMISSION

The probable magnitude of the power requirements of the near future, together with a quickened appreciation of need for maximum economy in its production has led to widespread and serious consideration of projects for bulk transmission of power to load centers from distant energy sources. It is of interest to note that similar conditions exist and similar projects are being considered in many foreign countries. The large amounts of power and the long distances involved in such projects are beyond the economic range of transmission voltages thus far in use. In consequence there has been, during the past year, considerable study and discussion of the feasibility, design, cost and characteristics of transmission at a materially high voltage.

The study and discussion have centered largely around 220 kilovolts which has appeared to represent a sufficient increase in transmission capacity to meet the requirements of projects thus far under discussion, and at the same time involve no such large step beyond present practise as to introduce problems not susceptible of present commercial solution.

Development of trunk transmission at such a voltage as 220 kv. would involve new problems arising from the high voltage, the large amounts of power involved, and the high service standards which the importance of the transmission would demand. The various studies which have been made indicate that these problems differ in degree, but not in character, from those satisfactorily handled in present practise. The production of equipment for such a voltage has been the subject of thorough study and investigation by the manufacturers, and definite assurance is given that equipment entirely adequate for the service can be supplied. For transformers in suitably large units for voltages of the order of 220 kv. it is stated that no radical departures are involved in either design or construction. As regards oil circuit breakers, where the problem is one of high capacity rather than of high voltage, it is claimed that satisfactory designs have been worked out. In general, for extr ahigh voltage installations the conclusions from various studies have been that design policy should tend to extreme simplicity of layout and staunchness of equipment. One feature of this policy would probably be omission of arresters or similar protective equipment. While present type of arresters could presumably be adapted for such a voltage, it appears to the opinion of those who have thus far studied the problem that they would be neither needed nor efficient. The idea appears to be becoming quite general among operating engineers that arresters of the usual type, with a series gap, afford little protection against dangerous low-voltage high-frequency surges, while the need for protection against excess potentials becomes progressively less for the higher operating voltages. Both theoretically and in the light of such experience as is available, circuits operating near the corona limit will tend to be self protecting against excess potentials as a result of corona dissipation, while atmospheric lightning disturbances in general appear to have relatively less destructive effects upon lines and apparatus for the very high voltages.

It appears probable that the one problem of 220-kv. transmission to which present practise cannot satisfactorily be extended without considerable modification is that of line insulators. While it is believed that present commercial types of suspension disk insulators could be made to give acceptable service, they are not regarded as likely to prove wholly satisfactory. Even if it could be assumed that the deterioration which has constituted such a serious defect with the earlier disks has in recent types been adequately overcome, it would still appear that both the electrical and mechanical characteristics of these insulators are not well adapted to the conditions of extra high voltage service. With long strings there is an excessive concentration of potential on the end disks and very little would be added to the total flashover of the string by increasing the number of disks. For 220 kv. this condition appears to be so pronounced that probably some remedy would have to be devised. It has been suggested that grading by using several types of disks with different electrostatic capacities would effect an improvement in the potential distribution over the string, although maintenance would be somewhat complicated, while another suggestion is for the installation of suitably shaped electrostatic shields at the ends of the strings. A difficulty con-

sidered even more serious is that mechanically these disks are not strong enough, in a single string, to support with adequate margins of safety the extreme loads which have been assumed as called for by 220 kv. service, due to the large size of conductor, the long spans probably demanded by considerations of economy and the heavy design loadings which the high service standards would dictate. The complication attending the use of two-string or three-string assemblies for suspension units is considered highly undesirable. In view of these limitations of the present commercial type of high-voltage insulator, the need for an improved or radically different design for higher voltages has been strongly emphasized. Some of the insulator manufacturers appear to be making extensive investigations and experiments in this field.

The long lines and high load capacities per circuit, conditions which call for extra high voltage service, have led to the recommendation that voltage be controlled mainly at the receiving end, either by synchronous condenser installations operated as an integral part of the circuit or, where practicable, by the use of excess generator capacity in the receiving system. For a given amount of power to be transmitted, ample condenser capacity, by improving voltage regulation, would reduce the number of circuits otherwise needed and by reducing the values of line current would permit of economical use of smaller conductors.

For 220 kv. transmission the expensive character of substation apparatus and the greater insurance of immunity from operating troubles which is afforded by simplicity of system would both favor keeping to a minimum the number of connections. It may be presumed that the tendency in developing such a system will be to use the high voltage for trunk transmission only, existing lower voltage transmission systems or extensions thereof being employed in general to reach customers and minor or secondary load centers.

The practise of interconnecting power supply systems in adjacent territories, which, during the war, gained new impetus as a result of the need for obtaining the maximum effective output from existing generating capacity, has been further extended, and numerous plans are in progress or under discussion for interconnections of considerable magnitude. The great interconnected system in the Southeastern states has been extended and the interconnections reinforced.

This movement toward interconnection is hastening the tendency, already evident, toward uniformity and simplicity in transmission standards and practises. Standardization of voltages in multiples of 11 kv. is well established, accepted steps being 22 kv., 33 kv., 44 kv., 66 kv., 88 kv., 110 kv., 132 kv., and 154 kv., with 220 kv. projected as the next step. Certain earlier standard steps, such as 60 kv. and 100 kv., are no longer used except in connection with existing systems. The advantage of keeping these standard voltage steps to a minimum are so great, even more from the point of view of future interconnection than of economy in manufacture, that certain of the steps in the above list may fall into disuse. Eighty-eight kv. for instance, does not seem likely to be continued as a standard, while possibly either 33 kv. or 44 kv. and either 132 kv. or 154 kv., may tend to drop out. Sixty cycles, likewise, is becoming firmly established as the standard frequency for the United States, and its virtually exclusive use for general power supply can be predicted for the near future. The practise of using a grounded neutral connection for the higher voltages is considered to have clearly demonstrated its superiority and is rapidly supplanting the isolated delta connection, while for larger systems at least the preference for the grounded neutral connection is evident also in case of the lower voltages.

In general, it is coming to be clearly recognized that interconnection of power supply systems is not to be merely an occasional expedient but the normal condition, and that it will tend to become more and more extensive, adjacent systems being connected into groups, and these groups being joined by trunk transmission lines into systems covering a number of states, probably leading eventually to an interconnected system of nation-wide proportions. With this tendency toward widespread interconnection so unmistakeable, an important obligation rests upon the engineering profession to so plan present work as to enable it to fit into such development with a minimum of waste, particularly in such matters as standardization of voltages and frequencies in adjacent territories. The establishment of a comprehensive power supply system, district or regional, will mean much to the future of the electrical power industry and to the industrial future of the country, in which the question of power supply is clearly destined to become one of the determining factors.

Tendencies in Underground Cable Practise

The lack of accurate information on certain elements influencing the operation of underground cables, has in the past caused this branch of the transmission and distribution to be neglected to some extent, and some of the operating companies have been put to a great deal of trouble and expense on this account. At present, however, there is a growing interest in this subject which has already resulted in a marked improvement in the manufacture of cables, so that the carrying capacity of cables manufactured today is materially greater than that of cables manufactured a few years ago.

The principal improvement is the reduction of dielectric loss at relatively high temperature. This has been accomplished principally as the result of a thorough study of the properties of impregnating compounds. It is now possible to manufacture cable the rating of which will be decreased only a few per cent under temperature as high as 100 deg. cent.

These refinements in manufacture make the three phase underground cable fairly satisfactory for voltages up to 25,000, and for loads per circuit up to 10,000 kw., but if these limits are to be exceeded it will probably be necessary to go to single conductor construction.

During the past year there have been a great many serious burnouts on underground systems where trouble was communicated from one cable to another until sometimes a whole duct line was involved, and at present there is a great deal of attention being given to methods for the prevention of the spreading of such troubles.

Results have been improved by changes in the design of duct lines, such as the wider separation of ducts especially where they enter the manhole. This wider separation tends to prevent the communication of trouble from one cable to another which is very dangerous where there are a great number of important cables in one line. For the same reason it is now the prevailing practise to use some form of conduit construction that gives an individual wall of concrete around each duct, as concrete is a very good arc-resisting material.

Protection of cables from fire in manholes by cement covering is still the prevailing practise. Methods of applying the cement varies to some extent, but the results are uniformly satisfactory.

There is also a recognized advantage in installing separate duct lines for cables operating at widely different voltages in order to avoid the possibility of limiting the load on some of the cables on account of the temperature limits of cables working at another voltage. This temperature influence is very important and should always be considered when there is a possibility of extreme limitations being placed on some cables by the influence of others.

As regards sizes and types of underground cable, manufacturers report a steadily growing demand for cables of 350,000 to 500,000 cir. mils. There is also a tendency on the part of customers to specify sector type cable on account of the smaller overall diameter for a given copper cross section.

The installation of these large size cables makes it more difficult to bend and train the cable in manholes and in some cases requires a modification in the design of manholes to avoid sharp bends.

The rectangular manhole with duct openings in the center of, and flush with one wall, compels the bending of the cable at too short a radius. Oval or rectangular manholes can be used, but as these shapes are not entirely satisfactory, it has been proposed that the rectangular manhole be set at 45 degrees with the center line of the conduit, and the duct entrance be recessed so as to permit of training through the manhole with long radius bends.

The Hochstadter type of cable in which the individual conductors are covered with a thin metal foil, and the assembled conductors sheathed without belt insulation, is now being supplied commercially.

Users of split conductor cable report satisfactory operating results and state that the advantages of the selective protection obtained by the use of this type of cable more than offset the disadvantage of the smaller current-carrying capacity for a given duct size.

E. B. Meyer, *Chairman.*

ANNUAL REPORT OF THE IRON AND STEEL INDUSTRY COMMITTEE

To the Board of Directors,

DURING the Convention held at Lake Placid in June, 1919, Dr. C. P. Steinmetz in discussing the work of the technical committees of the Institute expressed the belief that the annual reports of such committees should be planned to provide for the use of the entire membership of the Institute, a comprehensive record of the present status and recent progress of electrical engineering in the particular industry or branch of the art to which each committee had been organized to apply itself.

Accordingly, Mr. Wilfred Sykes, the Chairman of the Board's Committee on Technical Activities, suggested to the various 1920 Technical Committees that their reports "should cover notable installations or developments during the year and in view of the fact that, in the past, little has been done in this respect, that the reports for 1920 might be a review of the state of the art up to date."

Guided by these suggestions it has been the aim of the Iron & Steel Industry Committee, to at least prepare as a foundation, the present status of electrical application to the iron and steel industry, upon which subsequent committees might base annual reports showing recent progress. The field is an extremely broad one dealing as it must, with practically every process in the transformation of the raw material inos the many forms of finished product. Electricity it utilized in the handling of the ore and provides the means of handling the finished products as well as the final heat treatment of the more highly developed products. From the mechanical point of view, it has been stated that from the ore to the finished product the hand of man has no occasion to touch the materials and it can be stated further that throughout this same transformation, practically no step is taken in which electricity is not playing an increasingly important part.

While the iron and steel industry in America, dates back into the country's earliest history, electricity only comparatively recently began to play its important part, to be more exact, about 1891. At present the total generating capacity required by the industry is approximately one million kilowatts and each new

development in the art of steel making opens up new fields for electrical application so that in many important respects, the making of steel is becoming an electrical industry.

Supplement A has been prepared to indicate the major applications of heat and power entering into the making of iron and steel products from the raw materials, and to show the extent to which electrical heat and power have been or may be applied. As to the auxiliary applications of power in the handling, manipulating, and finishing of the materials and products, electricity is almost universally used as supplementary data will show.

It was decided to consider the mining of the raw materials as outside the scope of the Iron & Steel Industry Committee and it has dealt only with the material after arrival at the blast furnace. Reference again to Supplement A will indicate the processes to which the Committee has applied itself. Furthermore, it has not been intended to prepare a handbook for electrical engineers engaged in the iron and steel industry, but rather provide a source of general information for the large proportion of the Institute membership engaged in the many other lines of electrical engineering.

Using Supplement A as a basis, memorandums have been or are being prepared along the following general lines, believing that brief considerations of each subject separately, could be used to better advantage and more readily added to than to attempt a consecutive description.

Blast Furnace Group

Memorandum A 1—The status of iron ore smelting in the electric furnace.

Memorandum A 2—Synthetic electric furnace pig iron.

" A 3—The electrical precipitation of dust of blast furnace gases.

Electric Melting Furnace Group

*Memorandum B 1—Statistical data—The growth of the application of electric furnaces.

* " B 2—Types and electrical characteristics.

Electric Heat Treatment Furnace Group

Memorandum C 1—Electrical heated soaking pits.

" C 2—Carbon resistor type furnaces.

" C 3—Typical heat treating plants (Carbon resistor).

* " C 4—Metallic resistor type furnaces.

Rolling Mill Group

*Memorandum D 1—Statistical data.

* " D 2—Types of Drives—Non Reversing — Adjustable — Speed — Reversing.

Miscellaneous Group

*Memorandum E 1—The electric hydraulic system as proposed for large forge presses.

The Committee has prepared and sent to all the principal Iron and Steel Companies, the following Questionnaire and the results will be tabulated as a general indication of the extent and characteristics of both electric power supply and application. This data will appear in the form of Supplement B at an early date.

ELECTRICAL STATISTICS

Name and location of plant..

POWER SUPPLY (period January to December, 1919, inclusive)

Purchased from central stations......................... kw-hours

Generated by own steam units from coal-fired boilers....... kw- "

*In preparation for issue at an early date.

Meetings and Papers

No attempt has been made to secure papers or arrange Institute meetings for the consideration of Iron & Steel Industry subjects, owing to the extensive interlocking of the memberships of the A. I. E. E. and the Association of Iron & Steel Electrical Engineers which holds monthly meetings of high grade in Pittsburgh, Cleveland, Chicago, Birmingham and Philadelphia. In some cases joint meetings between the local sections of these organizations have been successfully held and an extension of this practise is recommended. The nature of the papers presented at the A. I. & S. E. E. meetings is made clear by the list supplementing this report (Supplement C) and it is recommended that closer relations be established between the two organizations through the publication, in the JOURNAL of the A. I. E. E., of notices before and after the A. I. & S. E. E. meetings, together with other items of mutual interest.

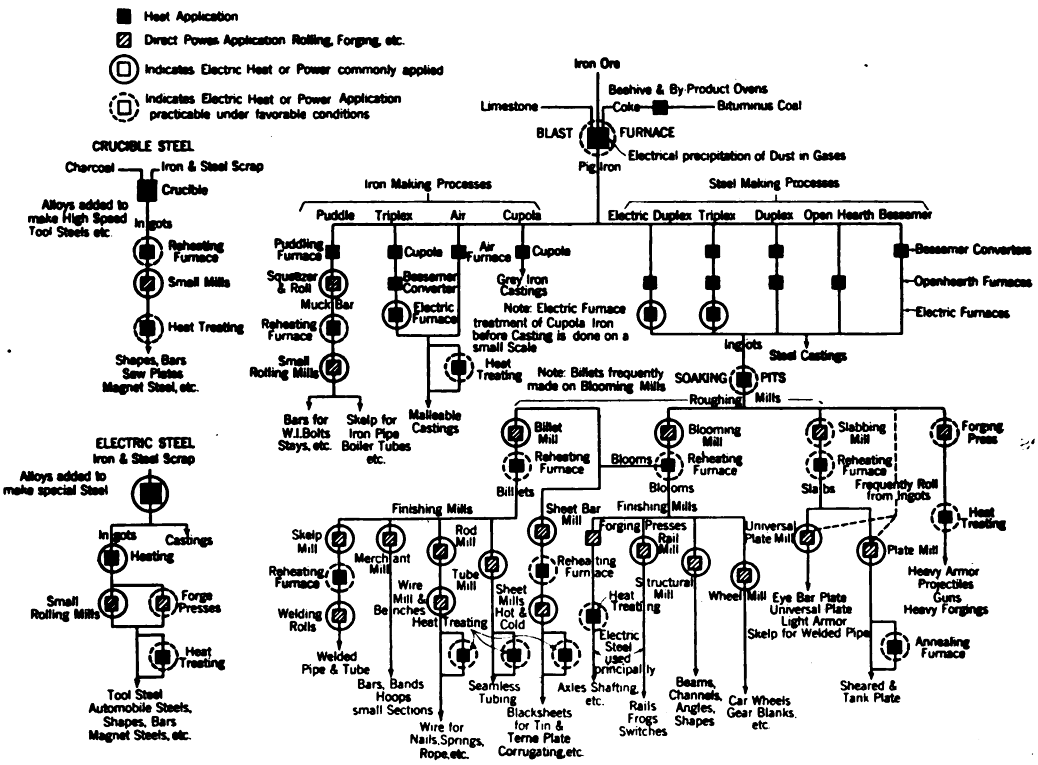
It is further recommended that the Board of Directors consider the scope of the work of the Association of Iron and Steel Electrical Engineers and with the appointment of the iron and steel industry committee for the coming year, formulate a definite policy as to the nature of the Committee's activities in order to avoid duplication of effort on the part of the two organizations, the memberships of which are closely interlocked.

The Board of Directors of the A. I. E. E. has authorized this Committee to discuss with the Board of the A. I. & S. E. E. the question of co-operation in the matter of Standardization Rules and it is regretted that no opportunity for such conference has presented itself. Such action is strongly recommended at an early date.

Many valuable papers relative to electric furnaces in the Iron & Steel making processes are presented in the meetings of the American Electrochemical Society and are recommended for notice and possibly publication in the A. I. E. E. JOURNAL.

The Committee wishes to acknowledge with thanks, the hearty co-operation it has received from the individuals and Companies appealed to in the gathering of the data presented herewith.

frequencies as high as 60 cycles, but 25 cycles is preferable in the large units, such as used in Sweden. The load factor can be made high and the units vary from 2000 to 7000 kw. in capacity. The furnace voltage is low, being below 100 volts, and voltage regulation is accomplished by means of taps in the high tension side which limits the use of very high transmission voltages without intermediate stepdown transformers.



ELECTRICITY IN THE MAKING OF IRON AND STEEL PRODUCTS

NOTE—Practically all auxiliary applications of power for the transportation, manipulation hoisting, pouring, shearing, finishing, magnetic lifting, etc. of the steel and iron materials, raw materials and machinery or tools used, are electrical.

MEMORANDUM A 1

THE STATUS OF IRON ORE SMELTING IN THE ELECTRIC FURNACE

The electric method of smelting of iron ore is in no sense competitive from a commercial point of view with the blast furnace, as commonly used in the manufacture of pig iron, in America.

Pig iron of high grade can be made in the electric furnace, and is so made in considerable quantities, but only at localities that combine the conditions of having ore and charcoal accessible to dependable low cost electrical energy, not exceeding twelve to fifteen dollars per horse power year. The industry has therefore, been confined largely to Norway, Sweden, Italy, with smaller installation in Japan, Switzerland, California and Canada. British Columbia is being considered as having the necessary requirements.

Three-phase furnaces are commonly used and power factors of from 65 to 95 per cent are possible with

The furnaces used in Sweden where the greatest amount of electric pig iron is produced (approximately 70,000 tons in 1918) consist of a furnace shaft quite similar to a small blast furnace independently supported above a relatively shallow crucible of larger diameter which is covered by a circular arch through which the carbon electrodes project into the charge which is fed to the top of the furnace as in a blast furnace.

MEMORANDUM A 2

SYNTHETIC ELECTRIC FURNACE PIG IRON

Conditions of shortage of pig iron and the unusual availability of steel turnings incident to the war period, developed the manufacture of synthetic pig iron in electric furnaces by re-carburizing fusion of steel turning or scrap. This process was used principally in Canada and France, the latter country having made at Levet, Nanterre and Limoges over 150,000 tons during the war period. The future of this industry depends upon cheap water power,

availability of materials and the relative cost of coal.

Typical Furnaces in Canada. A small 250-kw., single-phase furnace at Orillia, Ontario, produced six to seven tons of low phosphorus pig iron per twenty-four hours. A six-ton, three-phase furnace at St. Catherines, Ontario, with 1200-kw. transformers produced approximately 20 tons per day, with a 700-kw. input and with full 1200-kw. input—35 tons per day. For each hundred weight of turnings charged, there was added 5 per cent in the form of carbon and silicon and the yield was approximately 95 lb. of pig iron. The furnaces were of the enclosed type as usual to the making of steel and the current was of standard frequency. The load factor and power factor can be made high.

The French Furnaces. Open type furnaces of greater capacity, are used and are principally of single-phase construction with one moveable electrode and the other imbedded from below in the hearth. Standard frequencies with high load factor and power factor prevail. A 2500-kw. furnace produces 80 to 100 tons per day with a power consumption of 675 kw-hr. per ton. Complete foundries for the casting of shells were in some cases located adjacent to the pig iron furnace and by a further treatment in single-phase electric mixing furnaces of closed type, with an expenditure of approximately 50 to 100 kw-hr. per ton, the metal was made to meet the specifications for such castings (carbon 2.90, silicon 1.75, manganese 0.50, sulphur-trace, phosphorus 0.05).

These single-phase mixer furnaces are operated in groups of three and have one adjustable electrode above with the other electrode imbedded in the hearth from below.

MEMORANDUM A 3

The Electrical Precipitation of Dust of Blast Furnace Gases

The Cottrell system of electrical precipitation has been applied in two instances to the cleaning of blast furnaces gas. The advantages are such that such equipment is likely to become common among the blast furnaces.

In applying this system the gas piping from the blast furnace is arranged so that the gas is conducted through a group of vertical pipes from bottom to top and the high-tension electrode in the form of chains or wires held taut by weights, are supported in the center of the pipes from insulators at the top. The dust and fume particles are repelled by the charged electrode and are deposited on the sides of the pipes from which it is jarred by vibration of the pipes at suitable intervals (once each hour or more). This jarring can be accomplished automatically by relays adjusted to voltage drops and amperage increases which occur when the accumulation of dust becomes excessive. During the shaking down of the dust the precipitating apparatus is shut down for the necessary two or three minutes required.

A typical installation, put into service during 1919, takes three-phase, 60-cycle, 220-volt current from the power system, two 25-kv-a. transformers in open delta being ample for the entire power requirement which is 15 to 20 kv-a. to clean 45,000 to 50,000 cubic feet of gas per minute. The 220-volt current is applied to a small synchronous motor operating at 1800 rev. per min. and driving a mechanical rectifier, and is also fed through transformers which step the voltage up to 35,000 to 50,000 volts, adjustable by taps. The rectifier converts this high-tension current to the undirectional current required by the precipitating electrode. The equipment can be made to suit any standard frequency.

A second installation has been made more recently in connection with a blast furnace and is of about one half the capacity of the first equipment.

MEMORANDUM C 2

Carbon Resistor Type Furnace for Steel Treating

Furnaces of this type are usually rectangular in shape with doors at each end for the receipt and delivery of the materials to be treated. Parallel with the length of the furnace, one on each side, are located two resistor troughs. The resistance elements composed of broken carbon are thrown loosely into these carborundum fires and troughs which are supported on brick pillars along the side wall and protected by being recessed back from the space into which the steel materials are introduced. The heat from the resistance element is radiated to the walls and top of the furnace which is lined with refractory materials which become heated and in turn heat the charge. Carbon or graphite electrodes at each end of the troughs provide the means of introducing the current and the control of the current, hence the heat is effected by varying the voltage impressed at the electrodes, this variation being obtained by means of numerous taps on the secondaries of the special transformers.

The materials to be treated are in some cases put into the furnace on cars for a period treatment and in other cases the operation is continuous, the materials being slowly pushed or conveyed through the furnace.

Advantage is invariably taken of the possibility of making these furnaces automatic, both as regards the cycle of temperature treatment and the charging and discharging.

The following list of furnaces, together with the dates of installation, will indicate the development and application in steel treating:

Plant	Date	Application	No.	Electrical capacity each	Tons of steel heated per 24 hours
No. 1	1915	Annealing castings	1	150 kw.	12
2	1916	Annealing castings	1	300 kw.	24
3	1916	Treating draw-bar knuckles	2	1–600 kw. 1–300 kw. Tandem operation	144 total
4	1916	Annealing steel castings	1	600 kw.	12
5	1917	Treating small steel parts for aeroplanes and tractors	1	150 kw.	24
6	1917	Treating auto gears	1	40 kw.	4
7	1918	Duplicate of plant	3		
8	1918	Duplicate of plant	5		
9	1918	Annealing R. R. axles	1	150 kw.	12
10	1918	Treating cast steel anchor chain	2	1–600 kw. 1–300 kw. Tandem operation	150 total
11	1918	Treating Crank shafts for liberty motors		1–600 1–300 Tandem operation	144 total
12	1918	Annealing steel	1	600 kw.	75
13	1919	Roller bearing and ball race treatment	1	150 kw.	12
14	1919	Annealing steel sheets	1	600 kw.	150
15	1919	(2) Duplicate of plant	10		
16	1920	Treating bolts and nuts	1	40 kw.	4
17	1920	Roller hardening	1	75 kw.	5

MEMORANDUM C 3

Typical Heat Treating Plants

(Carbon Resistor Type)

Plant A. Automatic furnace handling roller bearing and ball races.

Materials to be treated are placed in metal baskets holding approximately 125 lb. each and fed into one end of rectangular carbon resistor type of furnace maintained at approximately 1525 deg. fahr. by an input of 150 kw. A clock contactor regulates, over a variable range, the rate of flow of material through the furnace and ordinarily 1000 to 1200 pounds of material is handled per hour.

The discharge of the heated material is into a drawing or quenching tank, the oil of which is maintained at a temperature of approximately 350 deg. fahr. by means of immersed nichrome resistors requiring about 40 kw.

The temperature control of the furnace and drawing tank is by pyrometers and the adjustable clock contactor devices make the operation entirely automatic as to the temperature, the time in the furnace and the time in the tank. Motor-driven conveyers, door operating mechanisms and oil pumps are all under the control of the time and temperature measuring devices.

Plant B. Annealing furnace for treating low carbon cold rolled strip.

The annealing furnace is approximately 225 ft. long and 22 ft. wide with the heated chamber in the middle. Two parallel tracks pass through the furnace and heated chamber and cars of steel strip each holding about 20 tons of material are fed on to tracks from opposite ends, the purpose being to absorb in the cold carload on one track the heat from the heated carloads on the other track on the way to the discharge point.

The temperature attained in the electrically heated chamber is approximately 1200 deg. fahr. A movement of the cars takes place every six hours, discharging one twenty-ton car of material at each end or approximately 150 tons of annealed material per 24 hours with an electrical input of approximately 120 kw-hr. per ton.

Plant C. Annealing furnace for treating alloy steel.

Arrangement is similar to Plant B except furnace is shorter and the nature of the steel requiring a 40 hour treatment at about 1400 deg. fahr. The ten cars in the furnace at one time each hold 30 tons of steel or a total of 500 tons, 120 tons of which is in the middle electrically heated chamber. The delivery is approximately 72 tons per day with an electrical input of approximately 250 kw-hr. per ton of metal annealed.

ANNUAL REPORT OF THE INDUSTRIAL AND DOMESTIC POWER COMMITTEE

To the Board of Directors,

THE Industrial and Domestic Power Committee has continued its earlier plan of work without change or modification. We are convinced that it is sound. We know the results now appearing will justify the study. We strongly urge its continuance.

Eleven sub-committees are analyzing electrical power applications in eleven different branches of industrial activity. The analysis consist of a study of the various processes involved, the movements in the processes and the electrical application to the movements. No standardization studies are considered. This is a province of other committees. The work is entirely ethical. In no way is our work overlapping studies by other Institute committees, or by committees external to the Institute.

A similar study of the electrical power applications in the use of prominent industrial tools is being conducted.

The work is being reported by monographs. Each monograph comprises a section of sub-committee study, complete in itself and yet forming a part of the whole. Each sub-committee is planning its own work to its own ideas, but all in conformity to the general plan. In the final execution of the plan, a progression of monographs carefully edited and approved by the Industrial and Domestic Power Committee will reach Headquarters and will be available for presentation to Section or Institute meetings; for publication in the JOURNAL or for sale by Headquarters at a nominal fee. With the interest being generated in the plan, we look confidently for extremely valuable returns; for treatises on industry of practical value. They in no sense can replace the work of the consulting engineer. They should be a guide in the study and planning of industrial applications.

In our work we have been helped by men not of the main committee, but regularly appointed by the President to our several sub-committees. These appointments have been cheerfully accepted, and such results as are being obtained are because of their service, and we may suggest that this plan has brought into active Institute service men whose abilities for such service were not otherwise being reached.

The personnel of the several sub-committees follows:

1. SUB-COMMITTEE ON MOTORS WITH PARTICULAR REFERENCE TO SPEED TORQUE CHARACTERISTICS.

A. M. Dudley, *Chairman.*

R. H. Tillman, A. C. Lanier,
Wilfred Sykes, John C. Parker.

2. SUB-COMMITTEE ON DOMESTIC POWER APPLICATION.

H. Weichsel, *Chairman.*

James Dixon, C. L. Kennedy,
A. F. Welch, L. L. Keilholtz.
Bernard Lester, Edgar D. Doyle.

3. SUB-COMMITTEE ON APPLICATIONS IN PRINTING INDUSTRY.

W. C. Kalb, *Chairman.*

W. E. Date, John D. Nies,
J. C. Lincoln, Carl F. Scott.

4. SUB-COMMITTEE ON APPLICATIONS TO CRANES AND HOISTS.

R. H. McLain, *Chairman.*

H. W. Eastwood, E. Friedlaender,
James A. Shepard.

5. SUB-COMMITTEE ON APPLICATIONS TO MACHINE TOOLS.

H. D. James, *Chairman.*

T. E. Barnum, W. C. Yates,
W. T. Snyder, R. H. Goodwillie.

6. SUB-COMMITTEE ON APPLICATIONS TO PASSENGER AND FREIGHT ELEVATORS.

R. H. Goodwillie, *Chairman.*

H. D. James, H. P. Reed,
David L. Lindquist, Charles H. Roth.

7. SUB-COMMITTEE ON APPLICATION IN TEXTILE INDUSTRY.

H. W. Cope, *Chairman.*

C. T. Guildford, S. B. Paine,
J. C. Ramsay, D. H. Sadler.

8. SUB-COMMITTEE ON APPLICATIONS IN CEMENT INDUSTRY.

R. B. Williamson, *Chairman.*

H. Weichsel, C. A. Kelsey,
J. F. Siegfried, Arthur Simon,
S. A. Staege, M. R. Woodward.

9. SUB-COMMITTEE ON APPLICATION IN WOODWORKING INDUSTRY.

L. E. Underwood, *Chairman*

Truman Hibbard, Robert L. Smith
S. A. Staege.

10. SUB-COMMITTEE ON APPLICATION OF ELECTRIC ENERGY IN INDUSTRIAL HEATING.

E. V. Buchanan, *Chairman.*

T. E. Penard, H. O. Swoboda,
W. S. Scott, H. A. Winne.

11. SUB-COMMITTEE ON APPLICATIONS IN RUBBER INDUSTRY.

W. E. Date, *Chairman.*

M. Berthold, A. C. Bunker,
B. T. Mottinger, C. A. Rice,
H. F. Schippel.

Most of the sub-committees have made reports of their activities for the term. It is impossible to give these complete in this report without making it unwieldy. It is impractical to condense them. They should have individual consideration, and their reading amplifies this picture of our work. For this reason they are forwarded herewith for the information and consideration of the Board of Directors. The sub-committees in the main have worked hard and conscientiously to develop the plan, the main committee acting as a clearing house, and in an advisory capacity. All sub-committee chairmen are members of the parent committee. But the burden of the work has fallen to the sub-committees, and their work merits every appreciation.

The outstanding feature in electrical industrial development during the present term has been magnitude of production. Demand has continued greater than supply taxing combined production to the greatest limit. Probably the development and increase in use of fractional horse power motors for domestic and small industrial use has been the greatest

contributing factor in this total. In this fractional field, quantity of production especially is to be emphasized. In general, quantity demand has been the real problem, the design and application of new productions being forced to second place.

In larger horse power fields, the increasing use of the synchronous motor is to be noted. As a corrective of the power factor of industrial loads it continues not only desirable but a growing necessity to meet a continual problem. In this connection, the use of the static condenser has continued as a power factor corrective.

The use of the direct-current motor in its several types continues accurately as does the use of the induction motor. In general there is continued progress in the standards of application of the several types of motors and in the recognition of these standards and away from misapplication, and great credit must be accorded to the discerning intelligence of the engineers connected both with the production and use of motors that has cooperatively tended to bring this about.

The Industrial and Domestic Power Committee particularly appreciates the advice of your committee on technical activities, together with the help constantly accorded from our Secretary's office at Headquarters. As a committee, we have tried to recognize fully the trust imposed and bespeak for our successors your full cooperation in the work we are undertaking.

A. G. Pierce, *Chairman.*

ANNUAL REPORT OF THE MARINE COMMITTEE

To the Board of Directors,

It will no doubt be recalled the inception of the Marine Committee was in 1913. Little actual work was accomplished by this Committee until last year, when the compilation of a set of rules for electrical installation on shipboard was started, together with dissemination of knowledge relative to that subject to the electrical engineers of the newly created ship yards.

The enormity of the work, that of preparing the Marine Rules started, was the more fully appreciated as the work progressed, and while the work of last year's committee was very commendable, the volume of the work completed was performed by this year's committee. The number of members constituting the committee this year was greatly reduced to facilitate the work and curtail expenses as much as possible.

Eight meetings of the committee were held. The first meeting was given over to the appointment of the various Committees and the outlining of the work of each. The Ship Installation, Marine Propulsion and Historical Committees constituted the main divisions. The first two of these committees were supplemented by sub-Committees to look after the vast amount of detail work involved in the activities of the main committee.

In last year's Annual Report of the Marine Committee it was suggested that the unfinished work of that Committee be continued this year. This unfinished work consisted of the completion of the rules for governing the installation of electrical apparatus on shipboard. The work on these rules that was not completed consisted of the following:

Revision of Rules prepared last year.
Control Equipments.
Alternating Current Apparatus Control.
Radio Installations.
Running Lights, etc.
Fire Alarm Systems.
(not completed by sub-Committees.)
Tabulation of Generating Sets.
Storage Battery Installation.
Gyro-Compass Installation.
Gyro Stabilizing Installation.
Tabulation of Wires and Conductors.
Appliances in vicinity of Compass.
